FERTILITY INHIBITOR HETEROBIMETALLIC COMPLEXES
OF PLATINUM(II) AND PALLADIUM(II):
SYNTHETIC, SPECTROSCOPIC AND ANTIMICROBIAL ASPECTS

ABSTRACT
Synthetic, spectroscopic and antimicrobial aspects of some fertility inhibitor heterobimetallic complexes have been carried out. These heterobimetallic chelates \([\text{M(CsH}_7\text{N}_3\text{EM}^2\text{Cl}_2}]\) (\(M = \text{Pd} \) or \(Pt\) and \(M^2 = \text{Si, Sn, Ti and Zr}\)) have been successfully synthesized via the reaction of \(M(C_5\text{H}_5\text{N}_2\text{Cl})\) with group four or fourteen dichlorides in 1:2 stoichiometric proportions. The products were characterized by elemental analyses, molecular weight determinations, magnetic susceptibility measurements, conductance, and IR, multinuclear NMR and electronic spectral studies. A square planar geometry has been suggested for all the complexes with the help of spectral data. Conductivity data strongly suggest that chlorine atoms are ionic in nature due to which complexes behave as electrolytes. All the complexes have been evaluated for their antimicrobial effects on different species of pathogenic fungi and bacteria. The testicular sperm density, testicular sperm morphology, sperm motility, density of cauda epididymis spermatozoa and fertility in mating trails and biochemical parameters of reproductive organs have been examined and discussed.

INTRODUCTION
The complexes of metal ions with macrocyclic ligands are significant because of their resemblance with many natural systems, such as porphyrins¹ and cobalamines². Many of the transition metal ions in the living systems work as enzymes or carriers in macrocyclic ligand field environment. Therefore, meaningful research in this direction might generate simple models for biologically occurring metallo enzymes³ and thus will help in developing our understanding of biological systems. These ligands are also of theoretical interest as they are capable of furnishing an environment of controlled geometry and ligand field strength⁴⁻⁷. A literature survey disclosed that a number of polydentate macrocyclic ligands and their metal complexes have been reported⁸. Their electronic properties and reactivities are resemble those of porphyrins.

On the other hand, the discovery of cisplatin, an important cytotoxic drug used in the treatment of a variety of human cancer, has given a new dimension to the coordination chemistry of platinum and palladium. It may be possible that useful anticancer drugs might be found among palladium complexes. A wealth of data has been accumulated in the search of novel potent antitumor agents. Transition metal chelates of nitrogen donor ligands have been extensively screened for their antitumor activity. Most of them showed some activity but significant activities were exhibited by palladium and platinum complexes. In principle, coordination compounds offer a great variety of shapes and reactivities for use in drug design, the most detailed advances have been in understanding how cis-DDP binds to DNA. A clear knowledge of how platinum antitumor drugs work would have major implications for the further design and improvement of these inorganic drugs. The use of metal as template in condensation reactions has led to the synthesis of a large number of metal complexes of macrocyclic ligands. Macrocyclic ligands are relatively rigid and thus impose a specific coordination geometry on the metal ion⁹. Macrocyclic ligands display a number of chemical interesting features which include unusual structures. The occurrence of metal exchange (transmetallation) reactions is used for the preparation of new metal complexes not accessible by direct synthetic procedure¹⁰.

A wider range of organosilicon compounds¹¹ is being studied due to their importance in resin and liquid polymer Chemistry¹²,¹³. Well known exemplary series of di and triorganotin halides with various nitrogen and oxygen/sulphur containing ligands¹⁴,¹⁵ have been found to possess significant biological and pharmacological activities. Screening data for tin derivatives¹⁶,¹⁷ have revealed that many more diorganotin compounds exhibit antitumour activity than the corresponding mono-,tri-, and tetra-organotins or the inorganic tin chemicals, while within the diorganotin class, the highest activity was given by the diethyl tin derivatives¹⁸. Similarly, some of the organotin have been evaluated as potential mosquito larvicides¹⁹. Transition metal complexes of nitrogen donor ligands have been studied in detail on account of their interesting stereochemistry and wide practical utility¹⁰,¹¹,¹². Transition metals and their complexes have evolved great interest due to their biological potential²²,²³ unusual structural aspects, unique stereo and magneto chemistry²⁴ and ability to form multiple complexes.
Several reports have appeared on multimetallic complexes associated with electrochemical, magnetic and spectroscopic studies and their stable complexes which are of biological interest but studies on the heterobimetallic complexes of palladium and platinum seem to be comparatively limited. Therefore, in view of the above facts it was considered as useful to synthesize such a type of compounds with an aim to characterize them structurally, electrochemically and biologically.

**MATERIALS AND METHODS**

All the chemicals and solvents used were dried and purified by standard methods. The reactions were carried out under strictly anhydrous conditions.

**Preparation of M(C₅H₇N₃)Cl₂**

The solution of MCl₂ (1 mmol) was mixed with the methanolic solution of 2,6 diaminopyridine (2 mmol). The reaction mixture was stirred for 6-7 hours. The resulting precipitate was recovered by filtration washed with methanol and dried in vacuo. The reactions proceed as: MCl₂ + 2C₅H₇N₃ → M(C₅H₇N₃)₂Cl₂.

**Preparation of Heterobimetallic Complexes**

Heterobimetallic complexes were synthesized by stirring a methanolic solution of M(C₅H₇N₃)₂Cl₂ with methanolic solution of group four or fourteen metal dichlorides Cp₂MCl₂, Ph₂MCl₂ and Me₂MCl₂. The reaction mixture was kept at room temperature for overnight and stirred for 6-7 hours to complete the reaction. The coloured solid compound separated out. The excess of the solvent was removed under reduced pressure and the complexes were dried for 3-4 hours in vacuo. The complexes were purified by crystallization. The yield was 60-70%. The analytical and physical data of the isolated precursor and their complexes are given in Table I.

| Complex                  | Colour    | M.P. (°C) | Analysis(%)          | Mol.Wt. Found (Calcd) |
|--------------------------|-----------|-----------|----------------------|-----------------------|
| Pt(C₅H₇N₃)₂Cl₂           | Light     | 110 (d)   | M 26.90 Pd/Pt 9.24 N 21.24 Cl 17.92 | 395.56    |

| Physical Properties and Analytical Data of Complexes

Conductivity measurements were made with a systronics model 305 conductivity bridge. The molecular weights were determined by the Rast camphor method. Infra red spectra of precursors and complexes were recorded in the range 4000-200 cm⁻¹ with the help of Nicolet-Megna FT-IR 550 spectrophotometer in KBr pellets. Electronic spectra were recorded on a Varian Cary/2390 spectrophotometer. ¹H NMR and metal NMR spectra were recorded in DMSO-d₆ versus TMS as standard on a JEOL FX–90Q spectrometer. Magnetic measurements
of powdered samples at the room temperature were recorded on a vibrating sample magnetometer Model 155 at the RSIC, IIT, Madras. Platinum, titanium, zirconium, tin and silicon were estimated gravimetrically as their oxides. Nitrogen was estimated by Kjeldahl's method, and chlorine by Volhard's method.

RESULTS AND DISCUSSION

The elemental analysis and spectral data are consistent with the formulations of the compounds as \(\text{M(C}_2\text{H}_7\text{N}_3)_2\text{Cl}_2\) and \([\text{M(C}_2\text{H}_7\text{N}_3)_2\text{Cl}_2\text{M}'_2\text{(R)}_4]\). The reactions of \(\text{MC}_{12}\) with \(\text{C}_2\text{H}_7\text{N}_3\) have been carried out in 1:2 molar ratios in methanol to yield \(\text{M(C}_2\text{H}_7\text{N}_3)_2\text{Cl}_2\). This complex reacts with group four or fourteen metal dichloride to yield heterobimetallic chelates \([\text{M(C}_2\text{H}_7\text{N}_3)_2\text{Cl}_2\text{M}'_2\text{(R)}_4]\).

The reactions proceed easily at room temperature. The coloured solid products so obtained are soluble in DMF and DMSO. The complexes are monomeric in camphor as indicated by the molecular weight determinations. Magnetic measurements showed them to be diamagnetic. However, the complexes are 1:2 electrolytes in DMSO as indicated by their molar conductance values (200-225 ohm\(^{-1}\) cm\(^{2}\) mol\(^{-1}\)).

SPECTRAL STUDIES

IR Spectra

The IR spectra of bimetallic complexes compare well the spectra of \(\text{M(C}_2\text{H}_7\text{N}_3)_2\text{Cl}_2\). The primary stretch is located at higher frequency than that of the corresponding secondary amine\(^{26}\). The spectra of \(\text{M(C}_2\text{H}_7\text{N}_3)_2\text{Cl}_2\) exhibit a broad and strong band in the range 3280 – 3140 cm\(^{-1}\) assigned to \(\nu(\text{N-H})\). This band is found at lower frequency (3098 cm\(^{-1}\))\(^{27}\) in the complex. This may be taken as an evidence for the coordination of secondary nitrogen to metal. Aromatic ring stretching (\(\sigma-\sigma\))\(^{28}\) are present at 1646, 1520 and 1468 cm\(^{-1}\). The presence of aromatic C-H and C-N bonds in the complex have been confirmed by the appearance of two bands at 3055 and 846 cm\(^{-1}\), respectively.

The coordination of nitrogen to the metal is further supported by the appearance of new bands of medium to weak intensity in the regions 581 cm\(^{-1}\) and 410 cm\(^{-1}\) attributable to \(\nu(\text{Si} \leftrightarrow \text{N})\)\(^{29}\) and \(\nu(\text{Sn} \leftrightarrow \text{N})\) vibrations, respectively. Apart from this, the band at 447 cm\(^{-1}\) and 442 cm\(^{-1}\) may be assigned to \(\nu(\text{Ti-C}_2\text{H}_3)\)\(^{30}\) and \(\nu(\text{Zr}-\text{C}_2\text{H}_3)\)\(^{31}\) vibrations. The bands at ca 520-550 cm\(^{-1}\) are due to \(\nu(\text{Ti-N})\)\(^{32}\) and \(\nu(\text{Zr-N})\)\(^{33}\) bonds.

\(^1^H\) NMR Spectra

The \(^1^H\) NMR spectra of the precursors and their complexes have been recorded in DMSO-\(d_6\) using TMS as an internal standard. The disappearance of the amine proton signal and the appearance of a secondary amine proton signal in case of bimetallic complexes indicated the deprotonation of the NH\(_2\) group after complexation. Chemical shift values of all the compounds are listed in Table II.

| Compound                  | -NH\(_2\) | -NH | -R | -Ph   |
|---------------------------|----------|-----|----|-------|

| Pt(C\(_2\)H\(_7\)N\(_3\))\(_2\)Cl\(_2\)Zr\(_2\)(C\(_6\)H\(_5\)) | -        | 7.93 | 6.42 | 7.00-7.29 |

\(^{119}\)Sn, \(^{29}\)Si and \(^{195}\)Pt NMR Spectra

The four coordination number of tin in these complexes were further get support by the appearance of sharp signals at \(\delta=31.23\) ppm in \(^{119}\)Sn NMR spectra\(^{34}\). In the cases of the silicon complexes, signals appeared at \(\delta=50.99\) ppm are assigned for tetra coordinated state\(^{35}\) around the silicon atom. \(^{195}\)Pt spectra show signals at \(\delta=2721\) ppm, indicative to tetra coordinated state\(^{36}\) of complexes.

\(^{13}\)C NMR Spectra

In the \(^{13}\)C NMR spectra of the precursors and their complexes, considerable shifts in the position of carbon atoms adjacent to atoms involved in complex formation clearly indicate the bonding of metal to the imino nitrogen atoms. Spectral data are given in Table III.
Table III: $^{13}$C NMR Spectral Data (δ, ppm) of Precursors and Their Corresponding Complexes.

Electronic Spectra
The formation of heterobimetallic complexes is further supported by the electronic spectra. Palladium (II) and platinum(II) complexes display d-d spin-allowed transitions due to three lower lying 'd' levels to the empty dₓ₂-y₂ orbitals. Transitions are located from ground state 1A½g to the exited states 1A₂, 1B₁g and 1Eg in order of increasing energy. Three d-d bands are assigned in the ranges 535 – 560 nm, 455–475 nm and 440 – 451 nm in the palladium complexes and 519–530 nm, 440 – 465 nm and 339–376 nm in the case of platinum complexes. These bands are attributed to 1A½g → 1A₂, 1A½g → 1B₁g and 1A½g → 1Eg transitions, respectively. These spectral values support the square planar geometry (Fig.1) around Pd(II) and Pt(II) and are in agreement with those reported earlier for square planar complexes.

BIOLOGICAL STUDIES
Such complexes have served as models for a number of biochemical processes. Therefore, all the complexes of palladium and platinum along with the precursors have been tested on various fungi and bacteria.

Antifungal Activity
The antifungal activity has been evaluated against several fungi by the radial growth method. The compounds were directly mixed with the medium in 100, 150 and 200 ppm concentrations. Controls were
also run and three replicates were used in each case. The linear growth of the fungus was obtained by measuring the diameter of the fungal colony after four days. The amount of growth inhibition in each of the replicates was calculated by equation \((C-T) \times 100\), where \(C\) is the diameter of the colony on the control plate and \(T\) is the diameter of the fungal colony on the test plate.

**Antibacterial Activity**

The antibacterial activity was determined by the inhibition zone technique. All the compounds were dissolved in methanol, paper discs of Whatman No. 1 paper with a diameter of 5mm were soaked in these solutions. These discs were placed on the appropriate medium previously seeded with organisms in Petri dishes and stored in an incubator at 30±1°C. The inhibition zone thus formed around each disc was measured in mm after 24 hours. Data of these activities are summarised in Tables IV and V.

The results reveal that the activity increases on complexation. The newly synthesized complexes have indeed been found to be more active in inhibiting the growth of fungi and bacteria than the precursors themselves. It may be postulated that these complexes might act as uncoupling agents of oxidation phosphorylation. The first uncoupling agent to be described, by Loomis and Lipmann\(^{39}\) was 2,4-dinitrophenol. Today many different uncoupling agents are known. Most are lipid soluble substances containing an acidic group and usually an aromatic ring. These agents allow electron transport to continue but prevent the phosphorylation of ADP to ATP. They uncouple the energy-yielding from the energy conserving reactions. Uncoupling agents function by breaking down a high-energy intermediate or state generated by electron transport. They can promote the passage of H\(^+\) ions through the cell membrane, which is normally impermeable to them. However, these agents are less effective for bacteria. The greater toxicity of metal complexes than the precursors can also be explained on the basis of the chelation theory\(^{40,41}\). Chelation reduces the polarity of metal ion mainly because of partial sharing of its positive charge with the donor groups and possible \(\pi\)-electron–delocalisation over the whole chelation ring. This increases the lipophilic character of the metal complex, which subsequently favours its permeation through the lipid layers of the organism cell membrane, and the normal cell process being impaired.

**Antifertility Activity**

Male rats obtained from ICMR, New Delhi were used. Animals were housed in steel cages and maintained under standard conditions (12 h light/ 12 h dark cycle; 25±3°C, 35 – 60% humidity), water and food were given ad libitum. Proven fertile male rats were taken and divided into nine groups of six each. The group A served as vehicle (olive oil) treated control. For groups B and F, starting material (PdCl\(_2\), 50mg/kg, b.wt.) suspended in olive oil was given for a period of 60 days. The animals of groups C, D and E received same dose of its Pd(C\(_5\)H\(_5\)N\(_3\))\(_2\)Cl\(_2\), [Pd(C\(_5\)H\(_5\)N\(_3\))\(_2\)Sn\(_2\)(CH\(_3\))\(_4\)]Cl\(_2\) and [Pd(C\(_5\)H\(_5\)N\(_3\))\(_2\)Sn\(_2\)(C\(_6\)H\(_5\))\(_4\)]Cl\(_2\) respectively for the same period. The animals of group F received starting material that is PtCl\(_2\), 50mg/kg, b.wt. suspended in olive oil. The animals of groups G, H and I received Pt(C\(_5\)H\(_5\)N\(_3\))\(_2\)Cl\(_2\), [Pt(C\(_5\)H\(_5\)N\(_3\))\(_2\)Sn\(_2\)(CH\(_3\))\(_4\)]Cl\(_2\) and [Pt(C\(_5\)H\(_5\)N\(_3\))\(_2\)Sn\(_2\)(C\(_6\)H\(_5\))\(_4\)]Cl\(_2\) respectively for the same period and dose. On the day sixty first, these animals were autopsied and testes, epididymis, seminal vesicle and ventral prostate
were removed, fat and connective tissue cleared off and kept at −20°C until assayed for total protein, sialic acid, cholesterol, fructose and glycogen by standard laboratory techniques.

Table VI: Alteration in the Body Weight and Weight of Reproductive Organs after Treatment with Various Compounds

See footnote of Table VI

Fertility Test

The mating exposure tests of all the animals were performed from day 55th to 60th. They were cohabitated with proestrous females in the ratio 1:3. The vaginal plug and the presence of sperm in the vaginal smear were checked for positive mating. The mated females were separated to note the implantation sites on day 16th of pregnancy through leproctomy.

Body and Organ Weight

No significant change was observed in the body weight after treatment with the compounds. A significant reduction in the weight of testes, epididymis, seminal vesicle and ventral prostate was observed after treatment with both the precursors and the compounds (Table VI).

Sperm Dynamics

Sperm motility in cauda epididymis and sperm density in testes and cauda epididymis were significantly reduced after treatment with both the precursors and their compounds (Table VII).

BIOCHEMICAL PARAMETERS LEADING TO INFERTILITY

Total Protein

Treatment with both the precursors as well as their complexes resulted in a significant reduction in the total protein contents of testes, epididymis, seminal vesicle and ventral prostate (Table VIII).
Table VIII: Effects of Precursors and Their Complexes on Total Protein Contents of Various Reproductive Organs of Male Rats

| Group | Treatment                        | Testes   | Epididymis | Seminal Vesicle | Ventral prostate |

Cf. Table VI
Glycogen

Testicular glycogen was depleted significantly in all experimental groups (Table IX).

Present study showed that oral administration of PdCl₂, PtCl₂, precursors and their complexes resulted in the reduction of weights of testes, epididymis, seminal vesicle and ventral prostate. The weight, size and secretory activities of sex accessories are closely regulated by androgen levels43. Reduction in sperm density and motility in cauda epididymis is of importance with regards to fertilization44. Significant reduction in the sperm motility and sperm density was observed in treated animals. This may be due to inhibitory effect of these compounds on the enzyme oxidative phosphorylation45. In our study various androgen dependent parameters that is total protein, sialic acid, fructose, cholestrol and glycogen revealed a significant decrease indicating that administration of these compounds resulted in the fall of circulating androgen46,47. It is inferred that compounds of Pd and Pt are found to be more effective than the starting materials in inhibiting the fertility.

ACKNOWLEDGEMENT

The authors are thankful to CSIR, New Delhi, India for financial assistance through grant number 01(1490)/EMR – II.
