4-Hexylresorcinol and silk sericin increase the expression of vascular endothelial growth factor via different pathways

You-Young Jo1, Dae-Won Kim2, Je-Yong Choi3 & Seong-Gon Kim1,4

Angiogenesis plays an important role in active inflammation and wound healing. Our results showed that silk sericin and 4-hexylresorcinol (4HR) increased vascular endothelial growth factor (VEGF) expression in a dose-dependent manner in RAW264.7 cells. Unlike 4HR, silk sericin increased the expression of hypoxia inducible factor-1α (HIF-1α) and HIF-2α. Pretreatment with an HIF inhibitor decreased the sericin-induced increase in VEGF expression. However, the HIF inhibitor did not affect the 4HR-induced increase in VEGF expression. An inhibitor of matrix metalloproteinase (MMP) declined the 4HR-induced increase in VEGF expression. Silk sericin increased production of reactive oxygen species (ROS), whereas 4HR decreased ROS. M1 markers were increased by silk sericin treatment, and M2 markers were increased by 4HR treatment. VEGF and angiogenin expression were higher in rats treated with a 4HR-incorporated silk mat than in rats treated with a silk mat alone. In conclusion, silk sericin and 4HR increased VEGF expression in RAW264.7 cells via HIF-mediated and MMP-mediated pathways, respectively. Silk sericin exerted pro-oxidant effects and 4HR exerted anti-oxidant effects. Rats treated with a 4HR-incorporated silk mat showed higher levels of VEGF and angiogenin than those treated with a silk mat alone.

Angiogenesis is a vital step in wound healing. Development of pro-angiogenic drugs is necessary to promote wound healing in patients with ischemic disease. Many foreign materials such as bacterial toxins or alloplasts can increase the expression of pro-angiogenic genes at the wound site1. This type of angiogenesis is considered inflammation-induced angiogenesis1. Although the angiogenesis is an essential step in the healing process, the role of inflammation-induced angiogenesis is limited to uneventful wound healing. Inflammation-induced angiogenesis is a mechanism to counter infection and is required for increasing phagocytic activity2. Although inflammation is an important step in the course of wound healing, it should be a transient step1,2. Normal wound healing should be followed by resolution of inflammation3. Accordingly, a pro-angiogenic agent with rapid wound-healing and anti-inflammatoriy properties would be useful1.

Agents that induce dormancy in micro-organisms typically reduce the metabolic rate of the micro-organism as a pro-survival mechanism4. High metabolic rate results in increased the production of reactive oxygen species (ROS), which are typically genotoxic and associated with inflammation5. Considering the relationship between metabolic rate and ROS production, agents that induce dormancy in micro-organisms may reduce any activity that increases the metabolism, such as inflammation, in multi-cellular living organisms. The phase transition from the acute inflammation to the healing is poorly understood. Macrophages play an important role in this phase transition from inflammation to remodeling in wound healing6–8. Macrophages that induce active phagocytosis are known as “M1-like macrophages”, which generate high levels of ROS7. M2-like macrophages play an
important role in the wound remodeling phase\(^7\). To date, no definite markers differentiate between M1 and M2 types of macrophages. ROS levels in macrophages are important in this phase transition.

Among various agents that induce dormancy in bacteria, resorcinol has been studied extensively \(^8\). 4-Hexylresorcinol (4HR) has been used as an antiseptic \(^9\) and anti-melanin agent in the food and cosmetic industries \(^10\). 4HR is a strong inducer of dormancy in microorganisms \(^11\). It exerts anti-cancer effects due to pro-apoptotic activity \(^12,13\). 4HR inhibits the nuclear factor-kappa B (NF-kB) pathway \(^14,15\) and decreases expression of tumor necrosis factor-\(\alpha\) (TNF-\(\alpha\)) in macrophages \(^16\). Both NF-kB pathway and TNF-\(\alpha\) play important roles in the inflammatory process \(^17\). Thus, 4HR can be used to accelerate the healing of deep burn wounds \(^16\). However, pro-angiogenic activity of 4HR has not been established. A recent study showed that 4HR increases levels of matrix metalloproteinases (MMPs) in the macrophages \(^18\). MMPs are proteolytic enzymes, and thus, the 4HR-induced increases in MMP expression accelerates the degradation of xenografts \(^19\) and silk fabric membranes \(^20\). The increase in pro-inflammatory MMPs induced by 4HR \(^18\) is contradictory to its anti-inflammatory effect \(^16\). 4HR has been reported to suppress foreign body giant cell formation \(^21\). MMP levels increase during the process of acute inflammation due to production by M1-like macrophages \(^6\). In addition, MMP levels increase during the tissue remodeling phase due to production by M2-like macrophages \(^7\). Levels of pro-angiogenic factors increase not only in chronic inflammation, but also under normal conditions. A membrane incorporated with silk and 4HR used for the guided bone regeneration technique was found to accelerate bone formation \(^22\). The anti-inflammatory effect of 4HR has been reported previously \(^16\). In this study, we investigated the pro-angiogenic effects of 4HR.

Sericin and 4HR increased expression of VEGF-A, VEGF-C, and angiogenin.

Silk sericin is a hydrophilic and adhesive protein produced by silkworms during formation of a cocoon \(^23\). In addition, silk sericin is an industrial byproducts that is considered a waste product \(^24\). The beneficial effects of silk sericin have been recently studied. Silk sericin is used in wound dressing materials and in cosmetics \(^24\). Silk sericin increases expression of TNF-\(\alpha\) in a dose-dependent manner \(^23\). TNF-\(\alpha\) is a strong activator of hypoxia inducible factors (HIFs) \(^25\), and HIFs can increase expression of vascular endothelial growth factors (VEGFs) \(^26\). Therefore, silk sericin may exert pro-angiogenic effects. Bacterial lipopolysaccharide (LPS) can increase the levels of HIFs and exert pro-angiogenic effects \(^27\). Silk sericin exhibits lower toxicity than LPS. However, the pro-angiogenic effects of silk sericin have not been examined.

As 4HR and silk sericin have different effects on expression of TNF-\(\alpha\) in macrophages \(^16,23\), the mechanism underlying their pro-angiogenic effects are expected to be different. Regulation of expression of HIFs and VEGFs is important for uneventful wound healing. Expression of HIFs increases in certain wounds to prevent hypoxic damage and accelerate phagocytosis during the healing process. A pro-angiogenic drug that inhibits expression of TNF-\(\alpha\) may be required for wounds that heal according to a HIF-independent mechanism of healing. The objective of this study was to evaluate the effects of 4HR and silk sericin on the expression of VEGF, HIF-1\(\alpha\), and HIF-2\(\alpha\). In addition, we used inhibitors of HIF and MMP to characterize the role of HIFs and MMPs in 4HR- or silk sericin-induced increases in VEGF expression.

**Results**

**Sericin and 4HR increased expression of VEGF-A, VEGF-C, and angiogenin.** Treatment of RAW264.7 cells with sericin or 4HR increased expression of VEGF-A, VEGF-C, and angiogenin in a dose-dependent manner (Fig. 1). As HIF is known to be a key transcription factor for angiogenesis \(^26\), the effect of sericin or 4HR administration on HIF expression was examined. Treatment with 10\(\mu\)g/mL sericin, but not 4HR, increased the expression level of HIF-1\(\alpha\) and HIF-2\(\alpha\) (Fig. 2). To assess the relationship of HIF in the expression of VEGF-A, VEGF-C, and angiogenin, phenethyl isothiocyanate (PEITC), an inhibitor of HIF, was used. Pretreatment with PEITC decreased the sericin-induced, but not 4HR-induced, increase in VEGF-A, VEGF-C,
and angiogenin expression (Fig. 3 and Supplementary Fig. 3B). Accordingly, sericin-induced increase in VEGF-A, VEGF-C, and angiogenin expression was HIF dependent.

MMPs and VEGFs are expressed in both inflammatory phase and remodeling phase. In addition, the expression of MMPs is closely associated with VEGF expression. As 4HR increases the expression of MMP-2, ARP100, an inhibitor of MMP-2, was used first. ARP100 did not decrease the 4HR-induced increase in VEGF-A expression (Supplementary Fig. 1). Accordingly, 4HR-induced increase in VEGF-A, VEGF-C, and angiogenin expression was not inhibited by blocking MMP-2 only. However, PD166793, broad-spectrum MMP inhibitor, decreased the 4HR-induced increase in VEGF-A, VEGF-C, and angiogenin expression (Fig. 4A and Supplementary Fig. 4B). According to the datasheet, the spectrum of MMP inhibition by PD166793 is dosage-dependent. As increasing PD166793 dosage, the inhibition spectrum of MMP is widening. When the applied 4HR concentration was set as 10 μg/mL, 4HR-induced VEGF-A expression was differentially inhibited by the dosage of PD166793 (Fig. 4B). As increasing the dosage of PD166793, 4HR-induced VEGF-A expression was inhibited more highly.

Sericin increased ROS levels, but 4HR decreased ROS level. The level of ROS is closely associated with inflammation. M1 type macrophages generate high levels of ROS. As M2-like macrophages are associated with remodeling, their ROS level is lower than that of M1-like macrophages. The relative ROS levels in the untreated control were 0.78 ± 0.006 (Fig. 5A). LPS (5 μg/mL to 20 μg/mL, p < 0.001) and silk sericin (10 μg/mL to 20 μg/mL, p < 0.001) treatment resulted in increased ROS production. ROS levels were significantly higher in response to 20 μg/mL LPS compared to 20 μg/mL silk sericin (P < 0.001). LPS treatment from 10 μg/mL to 20 μg/mL resulted in significantly decreased SOD levels (Fig. 5B; P < 0.005), but silk sericin did not alter SOD levels (P > 0.05). The relative SOD levels in response to 10, 15, and 20 μg/mL LPS treatment were significantly lower than those in response to the corresponding concentrations of silk sericin (P < 0.005).

The relative ROS levels in the H₂O₂ treated control were 2.35 ± 0.272 (Fig. 5C). ROS levels were significantly different between the untreated control the 10 μg/mL resveratrol group (P < 0.001). Furthermore, 4HR significantly reduced ROS at 5 μg/mL and 10 μg/mL (P = 0.021 and P < 0.001, respectively). No differences were observed between the 4HR and resveratrol groups (P > 0.05).
The relative total antioxidant capacity in the H₂O₂ treated control was 0.336 ± 0.029 (Fig. 5D). Treatment with 5 μg/mL and 10 μg/mL resveratrol significantly increased total antioxidant capacity compared to that in controls (P = 0.012 and < 0.001, respectively). In addition, treatment with 5 μg/mL and 10 μg/mL 4HR significantly increased antioxidant capacity compared to that of controls (P = 0.041 and 0.001, respectively). No differences were observed between the 4HR and resveratrol groups (P > 0.05).

The relative glutathione peroxidase activity in the H₂O₂ treated control was 0.275 ± 0.020 (Fig. 5E). Treatment with resveratrol significantly increased glutathione peroxidase activity at 5 μg/mL and 10 μg/mL (P = 0.003 and
<0.001, respectively). 4HR significantly increased glutathione peroxidase activity at 5μg/mL and 10μg/mL (P = 0.005 and <0.001, respectively). No differences were observed between the resveratrol and 4HR groups (P > 0.05).

**Sericin increased M1 marker proteins, but 4HR M2 marker proteins.** M1 type macrophages play an important role in inflammation and M2 type macrophages play an important role in remodeling1,6. Treatment of RAW264.7 cells with 10μg/mL sericin increased expression of the M1 markers CD68 and pStat1 (Fig. 6). Treatment of RAW264.7 cells with 10μg/mL 4HR increased expression of the M2 markers CD206 and c-Maf (Fig. 6).

**Compared to a silk mat alone, a silk mat incorporated with 4HR increased the expression of VEGF-A, VEGF-C, and angiogenin.** Immunohistochemical analysis showed that the expression levels of VEGF-A and angiogenin were significantly higher in the group treated with the silk mat incorporated with 4HR than in the group treated with the silk mat alone (Fig. 7A,B). Furthermore, expression levels of VEGF-A and angiogenin were significantly higher in the group treated with the silk mat with or without 4HR than those in the group without any graft (P < 0.05). Western blot results were consistent with the results of immunohistochemical analysis (Fig. 7C). Although the expression level of VEGF-A, VEGF-C, and angiogenin were increased in the group exposed to the silk mat containing 4HR, no significant differences were observed in the expression levels between groups treated with the silk mats containing 10% and 20% 4HR (P > 0.05). Interestingly, von Willebrand factor (vWF) was also highly expressed in the endothelium following grafting with silk mats containing 10% and 20% 4HR. In groups treated with a silk mat alone or no graft, vWF were mostly observed in blood cells (Supplementary Fig. 5).

**Discussion**

Our results showed that both sericin and 4HR increased expression of VEGF-A, VEGF-C, and angiogenin in *in vitro* (Fig. 1). In addition, expression levels of these proteins were increased *in vivo* in response to sericin and 4HR (Fig. 7). Sericin induced angiogenesis by increasing expression of HIF-1α and HIF-2α (Fig. 2). Sericin-induced increases in the expression of VEGF-A, VEGF-C, and angiogenin were inhibited by PEITC, which is a HIF inhibitor (Fig. 3). However, PEITC did not inhibit 4HR-induced expression of VEGF-A, VEGF-C, and angiogenin (Fig. 3 and Supplementary Fig. 3B). An MMP-2-selective inhibitor did not suppress the 4HR-induced increase in VEGF-A expression (Supplementary Fig. 1). A pan-MMP inhibitor (PD166793) decreased 4HR-induced VEGF-A, VEGF-C, and angiogenin expression (Fig. 4A and Supplementary Fig. 4B). ROS levels in RAW264.7 cells were increased by sericin administration, but were decreased by 4HR administration (Fig. 5). Expression level of M1 marker proteins was increased by sericin administration and expression of M2 marker proteins was increased by 4HR administration (Fig. 6). Thus, angiogenesis induced by 4HR was mediated by various MMPs and was independent of the HIF pathway (Fig. 8).

**Figure 6.** Sericin or 4-hexylresorcinol (4HR) administration and M1/M2 macrophage markers. Treatment with 10μg/mL sericin increased expression of CD68 and pStat1. Treatment with 10μg/mL 4HR increased expression of CD206 and c-Maf (C: untreated control).
M1-like macrophages are associated with inflammation, and many serious inflammatory diseases are associated with the stabilization of HIF. M1-like macrophages induce active phagocytosis and they generate high levels of ROS. M2-like macrophages play an important role in the wound remodeling phase. Destruction of the vascular network by trauma, infection, or autoimmune attack can induce ischemia, and subsequent inflammation. These conditions can stabilize HIF and increase the expression of VEGF. M1 and M2 macrophages are characterized by different protein expression profiles, but most of these proteins are controversial as differential.
markers of macrophage polarization. For examples, CD163+ cells have been traditionally identified as M2 macrophages, but this characterization has been questioned recently. CD206 was recently introduced as an M2 marker. In this study, 4 different potential markers were used for identification of M1 and M2 macrophages (Fig. 6). Sericin increased the expression level of CD68 and pSTAT1 which are known to M1 markers. CD206 expression was increased by the administration of 4HR (Fig. 6).

Sericin increased expression of TNF-α in a dose-dependent manner in our previous study. Exposure to TNF-α increased HIF-1α expression in macrophages under normoxic conditions. In this study, both sericin and LPS increased levels of ROS in RAW264.7 cells (Fig. 5A). SOD activity was decreased by sericin and LPS administration (Fig. 5B). Administration of sericin increased expression of HIF (Fig. 2). HIF is activated by ROS, and a previous in vitro study showed that hydrogen peroxide stabilizes HIF-1α without inducing hypoxia. Thus, activation of HIF by sericin administration might be mediated by increased ROS production. ROS are required for TNF-α-mediated stabilization of HIF-1α. Furthermore, some molecules, such as LPS, increase the half-life of HIF via direct stabilization, and these molecules are typically pro-inflammatory.

Considering the complex nature of the inflammatory response, sericin-induced increases in HIF expression may be beneficial or harmful depending on the specific type of HIF induced. In bacterial colitis, HIF-1α exerts protective effects on the mucosal barrier, but HIF-2α exerts pro-inflammatory effects. In addition, HIF-1α plays an important role in macrophage function in infectious diseases. AKB-4924 is a potent inducer of HIF-1α that exerts anti-microbial effects by activating macrophages. Sericin has anti-microbial properties, but the underlying mechanisms have not been characterized. The anti-microbial effect of sericin may be partly mediated by the stabilization of HIF-1α (Fig. 8).

Our results showed that the HIF inhibitor, PEITC, inhibited sericin-induced, but not 4HR-induced, increase in VEGF expression (Fig. 3 and Supplementary Fig. 3B). Some antioxidants can inhibit HIF stabilization. 4HR acts as an antioxidant by activating antioxidant enzymes. In this study, 4HR decreased ROS levels in RAW264.7 cells previously treated with H2O2 (Fig. 5C). In addition, total antioxidant capacity in response to 4HR was similar to that of resveratrol (Fig. 5D). Therefore, our results showed that 4HR did not increase HIF expression (Fig. 2) and 4HR-induced VEGF expression was decreased by PD166793 (Fig. 4 and Supplementary Fig. 4B).

MMPs cause proteolysis of matrix components and induce release of VEGF from the matrix in tumors. Some MMPs, such as MMP-9 and MMP-14, regulate VEGF expression, but the underlying mechanisms have not been characterized. VEGF-A expression is positively correlated with expression of MMP-1, MMP-2, MMP-3, and MMP-9 in atherosclerotic lesions. When the expression of MMP-2 and MMP-9 is inhibited by SB-3CT, selective MMP-2 and -9 inhibitor, VEGF-C expression is inhibited, too. MMP-14 increases VEGF-C expression. Angiogenin and MMP-9 are up-regulated in proangiogenic cells. Treatment of murine macrophages with 4HR increased expression of MMP-2, MMP-3, and MMP-9. Furthermore, administration of 4HR increased expression of MMP-13 and MMP-14 (Supplementary Fig. 2). An MMP-2 specific inhibitor (ARP100) did not decrease the 4HR-induced VEGF expression (Supplementary Fig. 1). PD166793 (20 nM) inhibited 4HR-induced expression of MMP-13 and VEGF (Fig. 4A). The IC50 of PD166793 for MMP-3 and MMP-13 were 12 nM and 8 nM, respectively. Therefore, 20 nM of PD166793 was sufficient to inhibit these MMPs. As increasing dosage of PD166793, inhibition of VEGF-A was increased (Fig. 4B). Inhibition of VEGF expression via MMP blockade has been observed in a xenograft model. MMPs are mainly found in the extracellular matrix, but are also found in the nucleus. MMP-3 and MMP-13 are often translocated to the nucleus and are involved in regulation of gene expression.

Nuclear MMPs may induce cellular apoptosis via proteolysis of nuclear proteins, and may directly regulate gene transcription. Intra-nuclear localization of MMPs and their involvement in transcription of VEGF might explain the mechanism of 4HR-induced VEGF expression (Fig. 8). However, how MMPs promoted VEGF expression in RAW264.7 cells remained unclear. To generalize our results, the effects of sericin and 4-HR on other macrophage cell lines or primary macrophages will be needed. These should be clarified forthcoming studies.

Therapeutic neovascularization is important in treatment of ischemic heart disease and diabetes mellitus, and in wound healing. In a previous study, VEGF therapy increased neuronal survival in a model of cerebral ischemia, and increased expression of VEGF facilitates coverage by pericytes and improves blood flow. A previous study showed that use of a silk mat with 4HR for vessel repair promoted endothelial regeneration. Thus, local delivery of VEGF may be beneficial in treating ischemia-induced tissue damage. Our results showed that a silk mat incorporated with 4HR increased angiogenesis significantly more than a silk mat alone (Fig. 7). Silk sericin increased markers for M1-type macrophages and 4HR increased markers for M2-type macrophages (Fig. 6). M1- and M2-like macrophages play an important roles in uneventful wound healing. Thus, our results indicate that a silk mat incorporated with 4HR may be used as a wound dressing or for the treatment of tissue damaged by ischemia.

Conclusion

Silk sericin and 4HR increased VEGF expression in RAW264.7 cells via HIF-mediated and MMP-mediated pathways, respectively. Silk sericin increased ROS levels in RAW264.7 cells, while 4HR decreased ROS. Silk sericin increased M1 markers, while 4HR increased M2 markers in RAW264.7 cells. The group treated with silk mats containing 4HR showed higher VEGF and angiogenin expression than the group treated with the silk mat alone.

Materials and Methods

Cell cultures and 4HR/sericin treatment. RAW264.7 murine macrophages (Korean Cell Line Bank No. 40071) were suspended in culture medium. Sericin was extracted by boiling silkworm cocoons kindly gifted by the Rural Development Administration (Wanju, Korea). 4HR was purchased from Sigma-Aldrich (St. Louis, MO, USA). RAW264.7 cells were placed in 6-well culture plates and treated with 1, 5, and 10 µg/mL of 4HR or...
sericin. After 2, 8, or 24 h of culture, the cells were collected. Cells in the control culture were treated with a volume of solvent equivalent to that required for 4HR and sericin.

**Western blotting.** Proteins were collected and mixed with a sodium dodecyl sulfate buffer. After heat denaturation, they were electrophoresed on 10% polyacrylamide gels. The gels were transferred to polyvinyldene difluoride membranes. After blocking, the membranes were probed with primary antibodies (dilution ratio = 1:500). The sources and specifications of primary antibodies were listed in the Supplementary Data. Blots were imaged and quantified using a ChemiDoc XRS system (Bio-Rad Laboratories).

**Expression of HIFs and HIF-1α inhibition assay.** To analyze expression of HIF-1α and HIF-2α induced by sericin or 4HR, we treated the cells with 10 μg/mL of 4HR or sericin. Subsequent steps for quantifying the different proteins were performed as described previously. The sources and specifications of primary antibodies were as follows: HIF-1α (Santa Cruz Biotech) and HIF-2α (Santa Cruz Biotech). PEITC is an inhibitor of HIF-1α.61 The optimal concentration of PEITC was determined using hydrogen peroxide (known HIF-1α inducer) (Supplementary Fig. 3). RAW264.7 cells were pretreated with dimethyl sulfoxide (DMSO) or DMSO + T10 μM PEITC. Then, the cells were treated with 10 μg/mL of 4HR or sericin, cultured for 24 h, and subjected to western blot analysis for VEGF-A.

**Effects of MMPs inhibition on 4HR-induced VEGF expression.** To analyze the effect of inhibition of MMPs on 4HR-induced VEGF expression, cells were treated with ARP100 or PD166793. ARP100 is an inhibitor of MMP-240 and PD166793 is an inhibitor of various MMPs60. The optimal concentration of ARP100 or PD166793 was determined using an MMP-induction experiment (Supplementary Figs 1 and 4A). Our results showed that 30 nM ARP100 and 20 nM PD166793 inhibited MMP-2 and MMP-13, respectively. After treatment with the inhibitors, the cells were treated with 1, 5, 10, or 20 μg/mL of 4HR. Subsequently, we performed the experiment as described above. Cells were collected after 24 h of culture, and western blot analysis for VEGF-A was performed. To assess the influence of PD166793 dosage, 10, 20, 50, or 100 μM of PD166793 was used for the pretreatment. After treatment with different dosages of PD166793, the cells were treated with 10 μg/mL of 4HR. Subsequent procedure was in accord to the above.

**Measurement of ROS and total antioxidant capacity.** ROS and superoxide levels after sericin administration were measured using commercial kits. The cellular culture conditions for RAW264.7 cells were the same as described above. Lipopolysaccharide (LPS) was used as positive control. Silk sericin or LPS were administered to RAW264.7 cells at 1, 5, 10, 15, and 20 μg/mL. After 24 h of cellular growth, ROS and superoxide levels were measured using a cellular ROS/Superoxide detection assay kit (CAT#: ab139476, Abcam). The procedure was performed in accordance with the manufacturer’s protocol. After incubating at 37 °C for 20 min, absorbance was measured at 450 nm. Superoxide dismutase activity was also evaluated under the same conditions using a commercial kit (CAT#: ab65354, Abcam).

Total antioxidant capacity after the administration of 4HR was measured using commercial kits. Cell culture conditions for RAW264.7 cells and H2O2 application conditions were the same as described above. Resveratrol was used as positive control. Resveratrol or 4HR were administered to RAW264.7 cells at 1, 5, and 10 μg/mL. After 24 h of cellular growth, total antioxidant capacity was measured using a total antioxidant capacity assay kit (CAT#: ab65329, Abcam). This procedure was performed according to the manufacturer’s protocol. After incubating at room temperature, absorbance was measured at 570 nm. Additionally, glutathione peroxidase assay was performed using a commercial kit (CAT#: ab102530, Abcam). After adding cumene hydroperoxide, absorbance was measured at 340 nm in a kinetic mode.

**Animals and experimental design.** Eight-week-old Crl:CD (Sprague-Dawley) specific pathogen-free (SPF)/VAF outbred rats (Orientbio Inc., Sungnam, Korea) were used in this study. All procedures were performed in accordance with guidelines for laboratory animal care and were approved by the Gangneung-Wonju National University for animal research (GWNU-2017-17). Thirty six rats (2–3 rats per cage) were housed under a 12-h light/12-h dark cycle in a controlled environment at 20–22 °C and 40% humidity for one week for acclimation in accordance with a previous publication.62 Briefly, the sections were prepared and enzyme predigestion was performed using a proteolytic enzyme (1 mg porcine trypsin, Sigma-Aldrich). Then, the sections were treated with hydrogen peroxide. After washing and blocking procedure, the sections were treated with primary antibodies.
(VEGF-A 1:50 and angiogenin 1:50). After conjugation with a universal secondary antibody (Dako REAL™ EnVision™/HRP, Rabbit/Mouse; Dako North America Inc.), the slides were stained with a mixture of diaminobenzidine chromogen and hydrogen peroxidase (Dako REAL™ DAB+ Chromogen and Dako REAL™ Substrate Buffer; Dako North America Inc.). Evaluation of relative staining intensity was performed according to previous our previous publication. Comparison among groups was done by ANOVA, with comparison between groups by Bonferroni’s method. Statistical significance was set at P < 0.05. In addition, immunofluorescence staining was performed on tissue sections with a von Willebrand factor antibody (dilution ratio: 1:100). After application of FITC-conjugated secondary antibody, counterstaining was done with DAPI.

The tissues surrounding the silk grafts were scraped from the backs of the rats, placed into micro-test tubes, and stored at −70 °C overnight (n = 5 for each group). The tissues were vigorously homogenized in a tissue protein extraction reagent buffer with a protease inhibitor cocktail, and western blot analysis was performed as previously reported.

Ethical approval and informed consent. The animal experiments in this study were approved by the Gangneung-Wonju National University for animal research (GWN-2017-17). All animal experiments were performed in accordance with the relevant guidelines and regulations.

Data Availability
All datasets used in this study were provided as Supplementary Data.

Acknowledgements
This study was carried out with the support of “Cooperative Research Program for Agriculture Science and Technology Development (Project no. PJ01313902)” Rural Development Administration, Republic of Korea.

Author Contributions
This study was designed by J.Y.Y. and K.S.G. K.D.W. performed in vitro experiments and data analysis. J.Y.Y., C.J.Y. and K.S.G. performed animal experiments. K.S.G. wrote the manuscript. K.S.G. and C.J.Y. performed critical review of the manuscript.
