Abstract. Starting from the lattice $A_3$ realization of the Ising model defined on a strip with integrable boundary conditions, the exact spectrum (including excited states) of all the local integrals of motion is derived in the continuum limit by means of thermodynamic Bethe ansatz techniques. It is also possible to follow the massive flow of this spectrum between the UV $c = 1/2$ conformal fixed point and the massive IR theory. The UV expression of the eigenstates of such integrals of motion in terms of Virasoro modes is found to have only rational coefficients and their fermionic representation turns out to be simply related to the quantum numbers describing the spectrum.

Keywords: algebraic structures of integrable models, conformal field theory, thermodynamic Bethe ansatz

ArXiv ePrint: 0710.4213
Introduction

It is well known that a deep connection exists between integrable models of statistical mechanics and integrable quantum field theories. In particular in quantum field theory the Yang–Baxter equation (YBE) plays an important role as a constraint on the 2-particle $S$-matrix. On the other hand in statistical mechanics the same equation appears as an equation satisfied by the Boltzmann weights. Boltzmann weights satisfying the YBE are then used to build families of commuting transfer matrices, which is another quite general feature of integrability for lattice models.

If we take as a prototype the $A_n$ RSOS models one finds that the Boltzmann weights can be understood as elliptic solutions of the YBE, and actually it is possible to recognize that the solutions one finds are connected with $S$-matrices in the sine–Gordon theory [1]–[3].

Furthermore it is well known that upon a suitable restriction of the couplings the sine–Gordon model is equivalent to minimal conformal field theories [4]–[6], and actually also the $A_n$ RSOS have been shown to be in the universality class of minimal CFTs [7].

Nonetheless the $A_n$ are in correspondence with CFTs only in an appropriate continuum limit called the UV scaling limit. In general there will be a continuum scaling limit depending on a mass parameter $\mu$ which will generate a RG flow to a massive IR theory, where the relevant processes will essentially be the scattering of kinks.

The continuum field theory corresponding to $A_n$ models can be interpreted as a bulk $\phi_{1,3}$ perturbation of the $\mathcal{M}_{n,n+1}$ minimal conformal field theory [6], which in the case of the Ising model is the thermal one. Such a perturbation is known to be integrable [8, 9], this means that there exists an infinite number of commuting charges which remain conserved in the perturbed theory.

In particular the first conserved quantity is the energy, if one considers its value on the vacuum state, known as the Casimir energy, it is well known that this is proportional
to the central charge of the underlying CFT in the UV limit [10, 11]. The flow to the IR
of such a quantity represents an example of the famous c-theorem.

A powerful tool for having access to the vacuum energy is the thermodynamic Bethe
ansatz (TBA) [12, 13] (for a review see [14]), which in some cases has been generalized to
excited states [7], [15]–[17].

In this work we derive the excited TBA equations for the $A_3$ model on a strip with
integrable boundary conditions by diagonalizing the transfer matrix. We then proceed to
define the continuum scaling limit of the transfer matrix eigenvalues which we then use as
generating functions for some quantities which we eventually identify with the conserved
quantities of the thermally perturbed conformal field theory.

It is then possible to analytically follow all the conserved quantities along the massive
flow to the IR theory. Comparison of the results which are obtained in the UV limit with
the spectrum of the BLZ [18, 19] local integrals of motion provides an exact identification
of the conserved quantities and allows to put the lattice integrable boundary conditions in
correspondence with the continuum integrable boundary conditions. It is well known that
in the continuum theory integrable boundary conditions are those which in the UV limit
preserve conformal invariance and are in one to one correspondence with the operator
content appearing in the Kac’s table of the corresponding minimal model [20, 21].

The eigenstates of the BLZ integrals of motion are computed in their Virasoro form,
and once expressed in terms of the fermion field turn out to be labelled by the same
quantum numbers which label the exact formula for their eigenvalues which has been
derived independently through TBA. Similar calculations involving the conserved charges,
for general perturbed conformal models, yet using a different lattice approach were
already carried out in a series of papers [22]–[24], although the analysis there was restricted
to the highest weight eigenvalues.

Excited states were also studied in the contest of the sine–Gordon theory in [25].

1. The $A_3$ model

The $A_3$ model is a lattice model which provides a convenient realization of the Ising
model. It is built on a square lattice where to each site $j$ is assigned a height variable
$a_j \in \{1, 2, 3\}$. The local height variables $a_j$ are constrained to satisfy an adjacency rule
which holds for $i, j$ nearest neighbours:

$$|a_i - a_j| = 1.$$

(1.1)

The model is characterized by its Boltzmann weights [26], which can be of two different
types: bulk weights and boundary weights. The only non-vanishing bulk weights are:

$$W\left( \begin{array}{cc} a \pm 1 & a \\ a & a \mp 1 \end{array} \right) = \frac{\theta_1(\lambda - u, q)}{\theta_1(\lambda, q)}$$

$$W\left( \begin{array}{cc} a & a \pm 1 \\ a \mp 1 & a \end{array} \right) = \frac{\sqrt{\theta_1((a - 1)\lambda, q)\theta_1((a + 1)\lambda, q)}}{\theta_1(a\lambda, q)} \frac{\theta_1(u, q)}{\theta_1(\lambda, q)}$$

$$W\left( \begin{array}{cc} a & a \pm 1 \\ a \pm 1 & a \end{array} \right) = \frac{\theta_1(a\lambda \pm u, q)}{\theta_1(a\lambda, q)}$$

(1.2)
while the non-vanishing boundary weights are:

\[
K_L \left( \begin{array}{c|c}
    a & a \\
    \lambda \\ 1
\end{array} \mid u \right) = \sqrt{\frac{\theta_1((a \mp 1)\lambda, q)}{\theta_1(a\lambda, q)}} \frac{\theta_4(u \mp \xi_L(a), q)\theta_4(u \pm a\lambda \pm \xi_L(a), q)}{\theta_4^2(\lambda, q)}
\]

\[
K_R \left( \begin{array}{c|c}
    a & a \\
    \lambda \\ 1
\end{array} \mid u \right) = \sqrt{\frac{\theta_1((a \mp 1)\lambda, q)}{\theta_1(a\lambda, q)}} \frac{\theta_4(u \pm \xi_R(a), q)\theta_4(u \mp a\lambda \pm \xi_R(a), q)}{\theta_4^2(\lambda, q)}
\]

where \( \lambda = \pi/4 \) is the so called crossing parameter, \( u \) is the spectral parameter and the \( \xi \) are related to the choice of boundary condition.

We also define the elliptic theta functions of nome \( q \) as

\[
\theta_1(u, q) = 2q^{1/4} \sum_{k=0}^{\infty} (-1)^k q^{k(1)} \sin((2k + 1)u) \\
|q| < 1
\]

\[
\theta_2(u, q) = 2q^{1/4} \sum_{k=0}^{\infty} q^{k(1)} \cos((2k + 1)u) \\
|q| < 1
\]

\[
\theta_4(u, q) = 1 + 2 \sum_{k=1}^{\infty} (-1)^k q^{k^2} \cos(2ku) \\
|q| < 1
\]

and this is the so called \( q \)-series, which will prove more useful to our goal, more typical definitions of these functions are given in terms of infinite products.

It is important to remark that the role of the nome \( q \) is to control the criticality of the model, which becomes critical as \( q \to 0 \). In what will follow we will focus on the region \( 0 < q < 1 \) which is the so called regime III of [7], actually this regime corresponds to a low temperature phase, but because of the duality symmetry of the Ising model this is the same as a high temperature phase.

Now, in terms of the above objects it is known that the model admits a transfer matrix description (on a lattice of width \( N \)):

\[
\langle a_1 \ldots a_{N+1} | \mathbf{T}(u) | b_1 \ldots b_{N+1} \rangle = \sum_{c_1 \ldots c_{N+1}} K_L \left( \begin{array}{c|c}
    b_1 & c_1 \\
    a_1 \\
    c_1 \\
    \lambda - u
\end{array} \right) \cdot \prod_{j=1}^{N} W \left( \begin{array}{c|c}
    c_j & c_{j+1} \\
    a_j \\
    a_{j+1} \\
    u
\end{array} \right) W \left( \begin{array}{c|c}
    b_j & b_{j+1} \\
    c_j \\
    c_{j+1} \\
    \lambda - u
\end{array} \right) K_R \left( \begin{array}{c|c}
    c_{N+1} & b_{N+1} \\
    a_{N+1} \\
    b_{N+1} \\
    u
\end{array} \right)
\]

such a transfer matrices form a one parameter commuting family with respect to the spectral parameter \( u \), and it is well known that this property makes the model integrable.

The transfer matrix \( \mathbf{T}(u) \) satisfies the following functional equation:

\[
\mathbf{T}(u) \mathbf{T}(u + \lambda) = \left( 1 + d(u) \right) F_N(u) \ S(u, \xi_L, \xi_R) = \mathcal{F}(u, q)
\]

doi:10.1088/1742-5468/2008/01/P01017
with

\[ F_N(u, q) = \left[ \frac{\theta_1(u - \lambda)\theta_1(u + \lambda)}{\theta_1(\lambda)^2} \right]^{2N} \] (1.8)

\[ S(u, \xi_L, \xi_R) = \frac{\theta_1(2u - 2\lambda)\theta_1(2u + 2\lambda)}{\theta_1(2u - \lambda)\theta_1(2u + \lambda)} A_L(u, q, \xi_L, a_L)A_R(u, q, \xi_R, a_R) \] (1.9)

where \( d \) is a matrix proportional to the identity that takes the form:

\[ d(u, q) = \mathbf{1}(-1)^N \left[ \frac{\theta_1(u)\theta_1(u - 2\lambda)}{\theta_1(u - \lambda)\theta_1(u + \lambda)} \right]^{2N} \left\{ \frac{\theta_1(2u)^2}{\theta_1(2u - 2\lambda)\theta_1(2u + 2\lambda)} \right\} \times \left( B_L(u, \xi_L, a_L)B_R(u, \xi_R, a_R) \right) \] (1.10)

being

\[ B_L = e^{-i\pi a_L} \times \frac{\theta_4(u + \pi/4 - \xi_L)\theta_4(u - \pi/4 - \xi_L)\theta_4(u + \pi/4 + \xi_L)\theta_4(u - \pi/4 + \xi_L)}{\theta_4(u - a_L\pi/4 - \xi_L)\theta_4(u + a_L\pi/4 + \xi_L)\theta_4(u - (a_L + 2)\pi/4 - \xi_L)\theta_4(u + (a_L + 2)\pi/4 + \xi_L)} \] (1.11)

\[ B_R = e^{-i\pi a_R} \times \frac{\theta_4(u + \pi/4 - \xi_R)\theta_4(u - \pi/4 - \xi_R)\theta_4(u + \pi/4 + \xi_R)\theta_4(u - \pi/4 + \xi_R)}{\theta_4(u - a_R\pi/4 - \xi_R)\theta_4(u + a_R\pi/4 + \xi_R)\theta_4(u - (a_R + 2)\pi/4 - \xi_R)\theta_4(u + (a_R + 2)\pi/4 + \xi_R)} \] (1.12)

\[ A_L(u, q, \xi_L, a_L) = \frac{\theta_4(u - \xi_L)\theta_4(u + \xi_L)\theta_4(u + a_L\pi/4 + \xi_L)\theta_4(u - a_L\pi/4 - \xi_L)}{\theta_4(\lambda)^4} \] (1.13)

\[ A_R(u, q, \xi_R, a_R) = \frac{\theta_4(u - \xi_R)\theta_4(u + \xi_R)\theta_4(u + a_R\pi/4 + \xi_R)\theta_4(u - a_R\pi/4 - \xi_R)}{\theta_4(\lambda)^4} \] (1.14)

The phases in the \( B \) terms may seem strange, but they turn out to be necessary. This fact has been observed also in [27] where the TBA equations for the \( A_3 \) model were derived.

Such a matrix satisfies a functional equation which for obvious reasons is called the inversion equation:

\[ d(u)d(u + \lambda) = \mathbf{1}. \] (1.15)

As a consequence of the simple form of the \( d \) matrix (which for more complicated models is not diagonal but is expressed in terms of \( T \) itself), we have that the functional equation written in terms of the eigenvalues \( T \) of \( T \) is independent of the eigenvalue under consideration.

Before moving on to discuss the TBA equations, it is useful to spend some word to comment on the periodicities of the transfer matrix \( T(u) \). Such periodicities come directly from the properties of the elliptic \( \theta \) functions and read:

\[ T(u + \pi) = T(u) \] (1.16)

\[ T(u - i\log q) = T(u), \] (1.17)
As a consequence we have that $T$ is a doubly periodic function which is completely defined by its analytic properties inside a rectangle that we may take as:

$$
\left(\frac{-\lambda}{2}, \frac{7}{2}\lambda \right) \times i \left(\frac{1}{2} \log(q), \frac{1}{2} \log(q)\right).
$$

If we now consider the functional equation (1.7) it is clear that $D$’s periodicities are inherited by the right-hand side $F(u)$ so that the object of our interest will be the zeros of $F$ inside the periodicity rectangle (1.18).

Such zeros can be shown by numerical analysis (indeed analytically in the critical limit [28]) to be organized on lines parallel to $u = \lambda/2 + ix$ with periodicity $\lambda$. It can be argued (see again [28] for the critical case) that as a consequence of the periodicities and of the structure of the functional equation (1.7) the eigenvalues $T(u)$ must have zeros which are organized in structures called 1-strings and 2-strings.

1-strings are just single zeros of real part $\lambda/2$ and imaginary part $0 < v_k < -1/2 \log q$ such that:

$$
T(\lambda/2 \pm iv_k) = 0 \quad k = 1, \ldots, m
$$

where $m$ denotes the number of 1-strings, while 2-strings are couples of zeros sharing the same imaginary part, while their real part takes the values $\lambda/2 \pm \lambda$, and we shall call their number $n$.

It is clear that a 1-string is a zero both for $T(u)$ and for $F(u)$, therefore is will be convenient in our case to look for such zeros in the expression for $F$. Such zeros could in principle be found in either one of the three factors of which $F$ is composed, but since (as we shall shortly see) $F_N$ and $S$ are going to be eliminated in the scaling limit 1-strings will essentially be zeros of the $(1 + d(u))$ term. It is finally worth mentioning that for finite $N$ it is possible to give a characterization of the states (i.e. transfer matrix eigenvalues) in terms of a non-increasing sequence of numbers $\{I_1, I_2, \ldots, I_m\}$ called quantum numbers (see figure 1) which express the position of 1-strings related to the position of 2-strings.

Each $I_k$ tells us how many 2-strings the $k$th 1-string has to go through in order to reach its position in the pattern of zeros starting from the configuration where all the 2-strings are heaped on the bottom, so that ordering the imaginary part of the 1-strings
On the integrable structure of the Ising model

$v_k$ into an increasing sequence $\{v_k\}_{k=1}^n$ we have that the quantum numbers $\{I_k\}$ must necessarily arrange into a non-increasing succession.

Clearly, the $I_k$ have to satisfy the following constraint:

$$I_k \leq n \quad \forall k.$$  \hspace{1cm} (1.20)

Such a characterization of the eigenvalues in terms of 1-strings and 2-strings also happens to give us a natural criterion for ordering the states, first of all we order the states by their increasing $m$ value, the ordering between equal $m$ states is done so that the state with all the 2-strings at the bottom of the tower comes first, and then each time a 2-string is pushed over a 1-string the ‘energy’ increases by one ‘unit’.

We shall see that in the continuum limit a more natural set of quantum numbers will arise to describe the pattern of zeros.

2. Excited TBA equations

In this section we are going to derive the excited state TBA equations for the $A_3$ model by solving (1.7). Considerable work has been done in the past on the excited states TBA, here we will essentially follow the work of [7], although similar techniques have been used also in [29].

First of all let us recall the form of the functional equation (1.7), we then define an $x$ coordinate in the following way:

$$u = \frac{\lambda}{2} + i \frac{x}{4}, \quad T_1(x) \overset{\text{def}}{=} T(u)$$

where we are going to solve (1.7) for the following values of $x$:

$$x \in (2 \log q, -2 \log q)$$

for convenience we will rewrite (1.7) after applying a translation:

$$u \rightarrow u - \frac{\lambda}{2}; \quad T \left( u - \frac{\lambda}{2} \right) T \left( u + \frac{\lambda}{2} \right) = F \left( u - \frac{\lambda}{2} \right)$$

we then use (2.1) to write (1.7) in the following form:

$$u = \frac{\lambda}{2} + i \frac{x}{4}, \quad T_1 \left( x + i \frac{\pi}{2} \right) T_1 \left( x - i \frac{\pi}{2} \right) = F \left( u - \frac{\lambda}{2} \right) = F \left( i \frac{x}{4} \right) \overset{\text{def}}{=} F_1(x).$$

At this point we could be tempted to follow the solution method used in [7] and try to Fourier expand the logarithmic derivative of (2.4), anyway before being allowed to do so, we have to remove the zeros of $T_1(x)$ in order to deal with an analytic function for which a Fourier expansion does make sense.

Now, if we consider what has been said in the previous section about the position of the zeros, one observes that for real $x$, $|x| < -2 \log q$, the function $T_1(x)$ which are due to the presence of 1-strings.

In order to reach our result we define the function

$$p(x, v_k) = \frac{\theta_1 \left( \frac{1}{q}(x - 4v_k), q^2 \right)}{\theta_2 \left( \frac{1}{q}(x - 4v_k), q^2 \right)}.$$  \hspace{1cm} (2.5)

\textit{doi:10.1088/1742-5468/2008/01/P01017}
We observe that the \( p \) function satisfies an equation which is similar to \( T_1(x) \):
\[
p \left( x + i \frac{\pi}{2}, v_k \right) p \left( x - i \frac{\pi}{2}, v_k \right) = 1
\]
(2.6)
furthermore we observe that \( p \) can be used to collect all the zeros (for real \( x \)) of \( T_1 \) through the product:
\[
\prod_{k=1}^{m} p(x, v_k) p(x, -v_k)
\]
(2.7)
so that we can assert that the function
\[
T_{ANZ}(x) \overset{\text{def}}{=} \frac{T_1(x)}{\prod_{k=1}^{m} p(x, v_k) p(x, -v_k)} = T_1(x) \prod_{k=1}^{m} \frac{\theta_2(\frac{i}{2}(x - 4v_k), q^2)}{\theta_1(\frac{i}{2}(x - 4v_k), q^2)} \frac{\theta_2(\frac{i}{2}(x + 4v_k), q^2)}{\theta_1(\frac{i}{2}(x + 4v_k), q^2)}
\]
(2.8)
does not have zeros for real \( x |x| < -2 \log q \) (ANZ stands for analytic and not zero).

We then observe that as a consequence of (2.6) \( T_{ANZ} \) still satisfies the functional equation:
\[
T_{ANZ} \left( x + i \frac{\pi}{2} \right) T_{ANZ} \left( x - i \frac{\pi}{2} \right) = \mathcal{F}_1(x)
\]
(2.9)
so that now one is authorized to Fourier expand the logarithmic derivative of the above equation. By means of some algebra one can determine \( T_{ANZ}(x) \), and thus \( T_1(x) \) to be:
\[
\log T_1(x) = \sum_{k=1}^{m} \log[p(x, v_k)p(x, -v_k)] + k \log \mathcal{F}_1 + D
\]
(2.10)
where \( k(x) \) is a convolution kernel defined as:
\[
k(x - y) = -\frac{1}{4 \log q} \sum_{k=-\infty}^{\infty} \frac{e^{ik\pi(x-y)/2 \log q}}{e^{-k \pi^2/4 \log q} + e^{k \pi^2/4 \log q}}.
\]
(2.11)
The convolution kernel \( k(x) \) can be computed in terms of elliptic \( \theta \) functions. It has been computed in [7] to have the following form:
\[
k(x, q) = \frac{\theta_2(0, q^4) \theta_3(0, q^4) \theta_3(ix, q^4)}{2 \pi \theta_2(ix, q^4)}
\]
(2.12)
Finally if we recall \( \mathcal{F}(u) \)'s definition we can write:
\[
\log \mathcal{F}_1(x) = \log \mathcal{F} \left( i \frac{x}{4} \right) = \log \left( 1 + d \left( i \frac{x}{4} \right) \right) + \log F_N \left( i \frac{x}{4} \right) + \log S \left( i \frac{x}{4}, \xi_L, \xi_R \right)
\]
(2.13)
so that remembering the expression for \( F_N(i(x/4)) \) we observe that its logarithm gives a contribution proportional to \( N \) and thus can be identified with a bulk energy term (which diverges in the thermodynamic limit \( N \to \infty \)), while \( S(i(x/4), \xi_L, \xi_R) \) gives a contribution independent of \( N \) which anyway diverges as we approach the critical regime \( (q \to 0) \) and can thus be identified with a surface energy.

Now, since in the next section we are going to deal with the continuum limit of \( \log T(u) \) (which consists both of \( N \to \infty \) and \( q \to 0 \)), it is natural to conclude by defining
On the integrable structure of the Ising model

a subtracted energy so as to give rise to meaningful quantities in the continuum limit:

\[ \log T_{\text{finite}}(x) \overset{\text{def}}{=} \log T_1(x) - k \ast \log \left[ F_N \left( i \frac{x}{4} \right) S \left( i \frac{x}{4}, \xi_L, \xi_R \right) \right] \]  

(2.14)

and, more explicitly:

\[ \log T_{\text{finite}}(x) = \sum_{k=1}^{m} \log[p(x, v_k)p(x, -v_k)] + k \ast \log \left( 1 + d \left( i \frac{x}{4} \right) \right) \]  

(2.15)

where we observe that the constant of integration \( D \) has finally disappeared in the subtraction, corresponding to a shift in the vacuum energy.

3. Scaling limit

Taking a scaling limit of a lattice model essentially means considering its critical behavior in the thermodynamical limit.

Such a double limit \(( N \to \infty, q \to 0 \)) can in principle be computed along infinite paths, however it can be shown [7] that there exists a prescription which allows us to obtain a meaningful limit for \( \log T_{\text{finite}} \).

such a prescription has the form:

\[ q = t^{1/2} \]  

(3.1)

\[ u = \frac{i}{4} (x + \log N) \]  

(3.2)

where the size \( N \) and the reduced temperature \( t \) satisfy:

\[ N \to \infty \]  

(3.3)

\[ N t^\nu = \mu \]  

(3.4)

\( \nu \) is understood as the critical exponent of the correlation length, which for the \( A_n \) models in regime III of [7] is known to be:

\[ \nu = \frac{n + 1}{4} \]  

(3.5)

The \( \mu \) parameter plays the role a regulator for the continuum system, and it will be used to generate a massive RG flow connecting the UV \(( \mu = 0 \)) and IR \(( \mu = +\infty \)) fixed points.

Such a regulator can be thought of as arising from the product of a mass \( m \) and a length \( R \):

\[ \mu = \frac{1}{4} m R \]  

(3.6)

being

\[ R = \lim_{N \to \infty, l \to 0} N l \]  

(3.7)

\[ m = \lim_{t \to 0, l \to 0} \frac{t^\nu}{l} \]  

(3.8)

and \( l \) is understood as the lattice spacing.

doi:10.1088/1742-5468/2008/01/P01017
Our first goal is to build a continuum version of \( d(u, q) \) which we will use to expand the continuum transfer matrix as a series whose coefficients will be the integrals of motion, we will then use the information we will gain to discuss the full continuum expression for \( \log T_{\text{finite}}(x) \).

The limit we are essentially interested in computing is the following:

\[
\hat{d}(x) := \lim_{N \to \infty} d \left( \frac{i}{4} (x + \log N), \left( \frac{\mu}{N} \right)^{1/2} \right) .
\]

From now on we shall fix the right boundary to \( a_R = 1 \) so that already before going into the scaling limit the R boundary term is fixed to:

\[
B_R = -1 .
\]

(3.10)

Therefore from now on the only surviving boundary height \( a_L \) will be simply called \( a \) and we shall realize in what will follow that \( a = s \) where \( s \) is the Kac label of \( \Delta_{r,s} \), and of course in this case \( r = a_R = 1 \).

In order to achieve the correct scaling behavior for the boundary term one has to postulate the following scaling behavior for the boundary parameter \( \xi \) (we are dropping the subscript \( L \)):

\[
\xi \sim \xi^* + \frac{1}{4} \log N .
\]

(3.11)

It is also useful to split the boundary term as:

\[
B = e^{i a} B^+ B^- \]

(3.12)

so that \( B^+ \) depends only on \( u + \xi \) and similarly \( B^- \) depends only on \( u - \xi \). Proceeding further one finds:

\[
\hat{B}^+ = \frac{1 - \mu^{1/2} e^{x/2} e^{-2i(\xi^* + \pi/4)}}{1 - \mu^{1/2} e^{x/2} e^{-2i(\xi^* + a(\pi/4))}} \quad \hat{B}^- = \frac{1 - \mu^{1/2} e^{x/2} e^{-2i(\xi^* - \pi/4)}}{1 - \mu^{1/2} e^{x/2} e^{-2i(\xi^* - a(\pi/4))}} .
\]

(3.13)

(3.14)

One then notices that in the UV limit \( \mu \to 0 \) the boundary \( \hat{B} \) flows into

\[
\hat{B} \sim e^{ia} \] (3.15)

and takes the value \(-1\) for \( a = 1, 3 \) and \(+1\) for \( a = 2 \).

After carrying out the calculation one finds the following continuum version of \( d \):

\[
\hat{d}(x, \mu) = e^{-8\mu \cosh(x + \log \mu)} \tanh^2 \left( \frac{x + \log \mu}{2} \right) (\hat{B}_L \hat{B}_R) .
\]

(3.16)

One should at this point discuss the scaling limit of the convolution term in \( \log T_{\text{finite}}(x) \), such a calculation turns out to yield:

\[
\lim_{N \to \infty, q \to 0} k * \log \left( 1 + d \left( \frac{i}{4} (x + \log N) \right) \right) = \int_{-\infty}^{+\infty} \frac{1}{2\pi \cosh(x - y)} \log(1 + \hat{d}(y)) \, dy .
\]

(3.17)

We can now deal with the scaling limit of the excitations.
As we approach the scaling limit the 1-strings will have the following asymptotic behavior ($y_k$ is the finite part):

$$4v_k \sim y_k + \log N.$$  
(3.18)

The 1-string term will then become:

$$\sum_{k=1}^{m} \log(p(x,v_k)p(x,-v_k)) \sim \sum_{k=1}^{m} \log \left( \frac{\tanh \left( \frac{x - y_k + \log \mu}{2} \right) \tanh \left( \frac{x + y_k + \log \mu}{2} \right)}{\tanh \left( \frac{x - y_k + \log \mu}{2} \right) \tanh \left( \frac{x + y_k + \log \mu}{2} \right)} \right).$$  
(3.19)

4. Expansion

4.1. Study of the ground state

We first of all begin by studying the behavior of the continuum ground state eigenvalue of the transfer matrix; in the previous section we have shown it takes the following form:

$$\log \hat{T}(x) = \int_{-\infty}^{+\infty} \frac{dy \log(1 + \hat{d}(y))}{2\pi \cosh(x-y)}$$  
(4.1)

such an expression, following the spirit of [30] has to be expanded in the following series:

$$\log \hat{T}(x) = -\sum_{n=1}^{\infty} C_n I_{2n-1}(\mu) e^{(2n-1)x}$$  
(4.2)

which in our case yields the following expression for the vacuum integrals of motion:

$$C_n I_{2n-1}^{vac}(\mu) = \frac{(-1)^n}{\pi} \int_{-\infty}^{+\infty} dy e^{-(2n-1)y} \log(1 + \hat{d}(y))$$  
(4.3)

We are now going to study this expression in the UV and IR limits.

We start by observing that the above expression can be manipulated into the form:

$$C_n I_{2n-1}^{vac} = \frac{(-1)^n \mu^{2(2n-1)}}{\pi 4^{(2n-1)}} \sum_{k=1}^{\infty} \frac{(-1)^{k+1}}{k^{2n}} \int_{0}^{\infty} \frac{dt}{t} e^{(2n-1)t} e^{-(t+16k^2\mu^2/\nu)} \left( \frac{t - 4k\mu}{t + 4k\mu} \right)^{2k} \left( B_R B_L \right)^k$$  
(4.4)

where we once we fix the right boundary to $a_R = 1 B_R$ disappears from the equations.

One at this point decides to get rid of $\xi^*$ fixing it to zero. Actually one could keep it, and let it scale once again as $\mu \to 0$ so that, for a suitable $\Lambda$:

$$\mu^{\Lambda} e^{4i\xi^*} = \tau.$$  
(4.5)

The parameter $\tau$ would then generate a flow between different conformal boundary conditions, see for example [31].

Now, by means of standard techniques one can prove that the following inequality holds for all values of $a$:

$$|C_n I_{2n-1}^{vac}(\mu)| \leq \frac{2\mu^{2(2n-1)}}{\pi} \sum_{k=1}^{\infty} \frac{1}{k} K_{1-2n}(8k\mu)$$  
(4.6)
where the $K_l(z)$ are the modified Bessel functions of the second kind. A study of the large $\mu$ asymptotics of the above series allows one to conclude that the ground states of the integrals of motion decay exponentially in the IR limit.

We are now ready to move our attention to the UV asymptotic behavior.

In the limit $\mu \to 0$ it is not difficult to show that:

$$C_n I^\text{vac}_{2n-1}(\mu) \sim \frac{(-1)^{n+1}}{\pi^2 (2n-1)} \Gamma(2n-1) \text{Li}_2(e^{i\pi a})$$

(4.7)

is the polylogarithm function. It is worth spending a word to observe that considering the energy $I_1$ one finds a dilogarithm of a phase, actually it is well known that the central charge is usually proportional to a dilogarithm. Furthermore one notices that all the vacuum expectation values of the integrals of motion are proportional to polylogarithms, this seems to be a rather general structure. One could ask himself if such polylogarithms satisfy sum rules similar to those holding for dilogarithms.

4.2. Excited states

We now ask ourselves what is the behavior of the excitation terms in the UV and IR and compare it with the ground states.

Now we want to expand the 1-string term.

The expansion is readily obtained if one considers the following identity:

$$\log \left( \frac{1 - t}{1 + t} \right) = -2 \sum_{k=1}^{\infty} \frac{2^{2k-1}}{2k-1}$$

(4.9)

and for example writes:

$$\log \tanh \frac{x - y_k + \log \mu}{2} = i\pi - 2 \sum_{n=1}^{\infty} e^{(2n-1)x} e^{-(2n-1)(y_k - \log \mu)} \frac{2n-1}{2n-1}.$$ 

(4.10)

Clearly one obtains the following result:

$$(1 - \text{string}) = -\sum_{n=1}^{\infty} 2^e^{(2n-1)x} \left( \sum_{k=1}^{m} e^{-(2n-1)y_k} + \mu^{2(2n-1)} e^{(2n-1)y_k} \right).$$

(4.11)

In order to proceed further it is necessary to have a closer look at the asymptotic behavior of the $y_k$.

Let us recall the equation satisfied by the $y_k$:

$$\hat{d} \left( y_k - i\frac{\pi}{2} \right) = -1$$

(4.12)

so that by taking the logarithm of both sides, using the expression for $\hat{d}$ given previously we have:

$$-4\mu (e^{-2i\lambda} e^{y_k} \mu - e^{2i\lambda} e^{-y_k} \mu^{-1}) + 2 \log \left( \frac{1 - e^{2i\lambda} \mu^{-1} e^{-y_k}}{1 + e^{2i\lambda} \mu^{-1} e^{-y_k}} \right) + \log(\hat{B}_L \hat{B}_R) = i\pi n_k$$

(4.13)

where the $n_k$ are odd integers.
On the integrable structure of the Ising model

We now introduce the following function:

\[ g_k(\mu) := \mu e^{y_k} \]  

(4.14)

we are now interested in expressing the \( y_k \) equation in terms of this new function \( g_k \), in order to do so we first rewrite the boundary term as:

\[ \hat{B} \left( y_k - \frac{\pi}{2} \right) = e^{i\pi a} \frac{(g_k + i)^2}{(g_k + i)^2 - 2i g_k (1 + \cos(\pi a))} \]  

(4.15)

so that the \( y_k \) equation becomes simpler and reads:

\[ 4i\mu \frac{(g_k^2 - 1)}{g_k} + \log \left( \frac{(g_k - i)^2}{(g_k + i)^2 - 2i g_k (1 + \cos(\pi a))} \right) = i\pi (n_k + 1 - a) \]  

(4.16)

this equation gives us the inverse function \( \mu(g_k) \), and we are interested in its behavior as \( \mu \to 0 \) and \( \mu \to +\infty \). In order to reach our goal it suffices to pick the branch of the \( \mu(g_k) \) function which passes through the origin, \( g_k \to 0 \) corresponds to the UV limit, whereas \( g_k \to 1 \) is the IR limit.

Expanding \( \mu \) around \( g_k = 0 \) we obtain:

\[ \mu \sim \frac{\pi}{4} \left( a - 1 - n_k \right) g_k + O(g_k^2). \]  

(4.17)

If we now decide to rewrite the 1-string term as follows:

\[ (1 - \text{string}) = -\sum_{n=1}^{\infty} \frac{2e^{(2n-1)x}}{2n-1} \mu^{p(2n-1)} \sum_{k=1}^{m} \left( g_k^{(2n-1)} + \frac{1}{g_k^{(2n-1)}} \right) \]  

(4.18)

we conclude by applying the above UV expansion that the expression

\[ \mu^{(2n-1)} \left( g_k^{(2n-1)} + \frac{1}{g_k^{(2n-1)}} \right) \]  

(4.19)

is UV limited, so that in this limit the excitations have the same scaling behavior as the ground state.

On the other hand the IR excitations cannot avoid to grow faster than the ground state term, this observation united to the fact that \( g_k \to 1 \) dictates the particular structure of the IR spectrum.

4.3. Full expansion

We finally have arrived at the point of writing the analytic expression for all the integrals of motion of the model, such expression reads:

\[ C_n I_{2n-1}(\mu) = \frac{2^{(2n-1)}}{2n-1} \sum_{k=1}^{m} \left( g_k^{(2n-1)} + \frac{1}{g_k^{(2n-1)}} \right) \]

\[ + \frac{(-1)^n}{\pi} \int_{0}^{+\infty} dy e^{-(2n-1)y} \log(1 + \hat{d}(y, \mu)). \]  

(4.20)

doi:10.1088/1742-5468/2008/01/P01017 13
In the limit $\mu \to \infty, g_k \to 1$ the ground state drops off exponentially, so that considering only the excitations it is immediate to realize that:

$$C_n I_{2n-1}(\mu) \sim \frac{4m\mu^{(2n-1)}}{2n-1}$$

(4.21)

this spectrum happens to be integrally spaced, and loses all memory of the quantum numbers aside from the length of the sequence of the $n_k$.

It is worth remarking that this result should not surprise us very much since it is very similar to what has been achieved in [32] for the $A_4$ model corresponding to the tricritical Ising model universality class.

In the UV limit it is clear from what we said so far that the integrals of motion have the following behavior:

$$C_n I_{2n-1}(\mu) \sim \left(\frac{\pi}{4}\right)^{(2n-1)} \left(\frac{2}{2n-1} \sum_{k=1}^{m} (a - 1 - n_k)^{(2n-1)} \right)$$

$$+ (-1)^n e^{i\pi a}((1 - e^{i\pi a})2^{-2n} - 1)\Gamma(2n - 1) \frac{\zeta(2n)}{\pi^{2n}}.$$  (4.22)

For $a = 1$ the energy takes the following form

$$C_1 I_1(\mu) \sim \pi \left(\frac{1}{2} \sum_{k=1}^{m} (-n_k) - \frac{1}{48}\right).$$  (4.23)

For $a = 2$ we have:

$$C_1 I_1(\mu) \sim \pi \left(\frac{1}{2} \sum_{k=1}^{m} (1 - n_k) + \frac{1}{44}\right).$$  (4.24)

For $a = 3$ we have:

$$C_1 I_1(\mu) \sim \pi \left(\frac{1}{2} \sum_{k=1}^{m} (2 - n_k) - \frac{1}{48}\right).$$  (4.25)

It is readily recognized that these formulae are in agreement respectively with the $h = 0$, $1/16$ and $1/2$ sectors of the minimal model $M_{3,4}$ if we choose:

$$C_1 = \pi.$$  (4.26)

One notices that in the vacuum sector $m$ must be even whereas in the $1/2$ sector $m$ must be odd for trivial reasons. In the $1/16$ sector $m$ must be odd but this fact is less trivial to understand from the formula, let us simply say that $m$-parity is fixed in the sector and is odd because for the highest weight state the only possible quantum number must satisfy $1 - n_1 = 0$.

We will understand better the structure of the quantum numbers in the next section.

If we now want to compute the constants $C_2, C_3$ in the vacuum sector of the model this can be done by using the explicit expressions for the integrals of motion, which can
be found in [18]:

\[ I_1 = L_0 - \frac{c}{24} \] (4.27)

\[ I_3 = 2 \sum_{n=1}^{\infty} L_{-n} L_n + L_0^2 - \frac{c+2}{12} L_0 + \frac{c(5c+22)}{2880} \] (4.28)

\[ I_5 = \sum_{m,n,p \in \mathbb{Z}} \delta_{m+n+p,0} : L_n L_n L_p : + \sum_{n=1}^{\infty} \left( \frac{11+c}{6} n^2 - \frac{c}{4} - 1 \right) L_n L_{-n} - \frac{c+4}{8} L_0^2 + \frac{(c+2)(3c+20)}{576} L_0 \]

\[ - \frac{c(3c+14)(7c+68)}{290304} \] (4.29)

where the \( : : \) denotes conformal normal ordering which can be obtained by arranging all the \( L_n \) in an increasing sequence with respect to \( n \).

So that we have the following vacuum expectation values:

\[ \langle 0 | I_3 | 0 \rangle = \frac{49}{11520} \] (4.30)

\[ \langle 0 | I_5 | 0 \rangle = -\frac{4433}{2322432} \] (4.31)

**Table 1.** UV state correspondence CFT \( \rightarrow \) TBA for the \( h = 0 \) sector.

| \( |0\rangle \) | \( |0\rangle \) | () |
| \( 2L_{-2}|0\rangle \) | \( \psi_{-3/2}\psi_{-1/2}|0\rangle \) | \((-1, -3)\) |
| \( L_{-3}|0\rangle \) | \( \psi_{-5/2}\psi_{-1/2}|0\rangle \) | \((-1, -5)\) |
| \( \frac{5}{2}L_{-4}|0\rangle - \frac{5}{2}L_{-2}^2|0\rangle \) | \( \psi_{-5/2}\psi_{-3/2}|0\rangle \) | \((-3, -5)\) |
| \( \frac{5}{2}L_{-4}|0\rangle + \frac{5}{2}L_{-2}^2|0\rangle \) | \( \psi_{-7/2}\psi_{-1/2}|0\rangle \) | \((-1, -7)\) |
| \( \frac{5}{2}L_{-5}|0\rangle - \frac{5}{2}L_{-3}L_{-2}|0\rangle \) | \( \psi_{-7/2}\psi_{-3/2}|0\rangle \) | \((-3, -7)\) |
| \( \frac{5}{2}L_{-5}|0\rangle + \frac{5}{2}L_{-3}L_{-2}|0\rangle \) | \( \psi_{-9/2}\psi_{-1/2}|0\rangle \) | \((-1, -9)\) |
| \( \frac{5}{11}L_{-6}|0\rangle - \frac{5}{11}L_{-4}L_{-2}|0\rangle + \frac{5}{112}L_{-3}^2|0\rangle \) | \( \psi_{-7/2}\psi_{-5/2}|0\rangle \) | \((-5, -7)\) |
| \( \frac{5}{11}L_{-6}|0\rangle - \frac{5}{11}L_{-4}L_{-2}|0\rangle + \frac{5}{112}L_{-3}^2|0\rangle \) | \( \psi_{-9/2}\psi_{-3/2}|0\rangle \) | \((-3, -9)\) |
| \( \frac{5}{2320}L_{-6}|0\rangle + \frac{1}{114}L_{-4}L_{-2}|0\rangle + \frac{5}{112}L_{-3}^2|0\rangle \) | \( \psi_{-11/2}\psi_{-1/2}|0\rangle \) | \((-1, -11)\) |
Actually these values of the vacuum constants \( C \) for the minimal model \( \mathcal{M}_{3,4} \) calculation allows one to verify that they are independent of the sector.

which gives us the following equations:

\[
C_2 \langle 0 | \mathcal{I}_3 | 0 \rangle = \frac{\pi^3 \Gamma(3)(1 - 2^{-3})}{4^9 90} \tag{4.32}
\]
\[
C_3 \langle 0 | \mathcal{I}_3 | 0 \rangle = -\frac{\pi^5 \Gamma(5)(1 - 2^{-5})}{4^5 945} \tag{4.33}
\]

so that we readily get:

\[
C_2 = \frac{\pi^3}{14} \tag{4.34}
\]
\[
C_3 = \frac{9}{175} n^5 \tag{4.35}
\]

This values for the vacuum constants \( C_n \) actually can be extracted from [19], so that in general we have for the vacuum sector the following expression:

\[
C_n = \frac{3^n 4^2 (2n)^{-1/2 + 2n} \pi^{-1/2} \Gamma(4n - 2)}{n! \Gamma(3n - \frac{1}{2})}. \tag{4.36}
\]

Actually these values of the \( C_n \) are computed from the vacuum sector, but direct calculation allows one to verify that they are independent of the sector.

We stress that the above formulas describe exactly the conformal spectrum of the minimal model \( \mathcal{M}_{3,4} \).

5. Fermionic modes and TBA quantum numbers

Actually the quantum numbers $n_k$ themselves have a very simple interpretation in terms of fermionic modes. To understand this one needs only to remember that the stress energy tensor for the Ising model is built out of the fermion field as:

$$ T(z) := \frac{1}{2} : \psi(z) \overleftarrow{\partial} \psi(z) : $$

so that by introducing the well known mode expansion

$$ i\psi(z) = \sum_n \frac{\psi_n}{z^{n+1/2}} $$

one gets

$$ L_n = \frac{1}{2} \sum_k (k + \frac{1}{2}) : \psi_{n-k} \psi_k : $$

where the fermionic modes will have a half integer index when we will be working in the 0, 1/2 sectors, whereas the index will be integer in the twisted 1/16 sector. It is then just a matter of unraveling the normal ordering and using the fermionic algebra $\{\psi_n, \psi_m\} = \delta_{n+m,0}$ to work out the fermionic expression for the eigenvectors of the integrals of motion. If we consider for example the sixth level of descending in the vacuum sector we have:

$$ 20L_{-6}|0\rangle + 24L_{-4}L_{-2}|0\rangle + 5L_{-3}^2|0\rangle = 112\psi_{-11/2}\psi_{-1/2}|0\rangle $$

$$ 4L_{-6}|0\rangle - 8L_{-4}L_{-2}|0\rangle + L_{-3}^2|0\rangle = 16\psi_{-9/2}\psi_{-3/2}|0\rangle $$

$$ 20L_{-6}|0\rangle + 24L_{-4}L_{-2}|0\rangle - 23L_{-3}^2|0\rangle = 56\psi_{-7/2}\psi_{-5/2}|0\rangle $$
Table 5. Table of eigenvalues in the 1/2 sector.

| TBA state | \( I_3 \) eigenvalue | \( I_5 \) eigenvalue |
|-----------|-----------------------|-----------------------|
| (1)       | 1729 \( \frac{1}{11520} \) | 67639 \( \frac{1}{2322432} \) |
| (-1)      | 45409 \( \frac{1}{11520} \) | 17599063 \( \frac{1}{2322432} \) |
| (-3)      | 210049 \( \frac{1}{11520} \) | 225220567 \( \frac{1}{2322432} \) |
| (-5)      | 576369 \( \frac{1}{11520} \) | 121399671 \( \frac{1}{2322432} \) |
| (-7)      | 1224769 \( \frac{1}{11520} \) | 45409 \( \frac{1}{11520} \) |
| (1, -1, -3) | 457089 \( \frac{1}{11520} \) | 242806135 \( \frac{1}{2322432} \) |
| (-9)      | 1224769 \( \frac{1}{11520} \) | 242806135 \( \frac{1}{2322432} \) |
| (1, -1, -5) | 623329 \( \frac{1}{11520} \) | 1228895239 \( \frac{1}{2322432} \) |
| (-11)     | 3661009 \( \frac{1}{11520} \) | 26759824663 \( \frac{1}{2322432} \) |
| (1, -1, -7) | 1224769 \( \frac{1}{11520} \) | 45409 \( \frac{1}{11520} \) |
| (1, -3, -5) | 787969 \( \frac{1}{11520} \) | 1436606743 \( \frac{1}{2322432} \) |

so that comparing with table 1 we see that \( n_k/2 \) are simply the labels of the fermionic
modes, and we can easily either guess or explicitly work out straightforwardly the form
of all the other eigenstates which is obvious aside from a normalization.

Similarly in the 1/2 sector one has at level 6:

\[ 36L_{-6}|1/2\rangle + 27L_{-5}L_{-1}|1/2\rangle + 8L_{-4}L_{-2}|1/2\rangle = 288\psi_{-13/2}|0\rangle \]  
\[ 36L_{-6}|1/2\rangle - 45L_{-5}L_{-1}|1/2\rangle + 8L_{-4}L_{-2}|1/2\rangle = 144\psi_{-9/2}\psi_{-3/2}\psi_{-1/2}|0\rangle \]  
\[ 108L_{-6}|1/2\rangle + 81L_{-5}L_{-1}|1/2\rangle - 26L_{-4}L_{-2}|1/2\rangle = 72\psi_{-7/2}\psi_{-5/2}\psi_{-1/2}|0\rangle \]  
so that the fermionic modes have indexes which are simply \((n_k - 2)/2\) and one understands
how the fermionic representation of table 2 should be.

The 1/16 sector has to be worked out expanding the Virasoro modes in integer
fermionic modes, this is not very different from the previous situation, except for the
presence of the zero mode \( \psi_0 \) which generates the zero-mode algebra:

\[ \psi_0|1/16\rangle_- = \frac{1}{\sqrt{2}}|1/16\rangle_+ \]  
\[ \psi_0|1/16\rangle_+ = \frac{1}{\sqrt{2}}|1/16\rangle_- \]  
so that actually there are 2 1/16 vacua, one has no 1-strings (\(|1/16\rangle_+\)) and the other has
1 1-string (\(|1/16\rangle_-\)). The fermionic modes have indexes which are simply \((n_k - 1)/2\), so
that the (1) quantum number is recognized as coming from the insertion of \( \psi_0 \).

doi:10.1088/1742-5468/2008/01/P01017
Table 6. Table of eigenvalues in the 1/16 sector.

| TBA state | $I_3$ eigenvalue | $I_5$ eigenvalue |
|-----------|------------------|-----------------|
| (1)       | $-\sqrt{2}/4$   | $\sqrt{2}/4$   |
| (-1)      | $1/8$           | $1/8$           |
| (-3)      | $-\sqrt{2}/4$   | $\sqrt{2}/4$   |
| (1, -1, -3) | $1/8$         | $1/8$           |
| (-5)      | $5/16$          | $5/16$          |
| (1, -1, -5) | $1/8$         | $1/8$           |
| (-7)      | $7/16$          | $7/16$          |
| (1, -3, -5) | $1/8$         | $1/8$           |
| (1, -1, -7) | $1/8$         | $1/8$           |
| (-9)      | $9/16$          | $9/16$          |
| (1, -3, -9) | $1/8$         | $1/8$           |

For example one has:

\[ |1/16\rangle_- = \sqrt{2}|0\rangle^+ \]

(5.12)

\[ L_{-1}|1/16\rangle_- = \frac{1}{2\sqrt{2}}\psi_{-1}|1/16\rangle^+ \]

(5.13)

\[ L_{-2}|1/16\rangle_- = \frac{1}{\sqrt{2}}\psi_{-2}|1/16\rangle^+ \]

(5.14)

so that comparing with table 3 we easily understand the how things work out and, once again, aside from the normalizations one knows perfectly from the beginning which results one will find upon expressing eigenstates in terms of fermionic modes.

It has to be remarked that the fermionic description of the eigenstates of the RSOS transfer matrix fits naturally into the description of [33], where it is shown that the TBA quantum numbers can be described also in terms of ‘fermionic paths’.

Finally one notices that the TBA quantum numbers appearing in the 1/16 and in the 1/2 sector are actually the same, this can be understood from the existence of a boundary flow connecting the 2 sectors, see for example [34].

doi:10.1088/1742-5468/2008/01/P01017
6. Conclusion

In this work we have derived the excited TBA equations for the A3 model defined on a strip with integrable boundary conditions. The continuum limit of the TBA equations was then derived and an expansion defined which led to integrals of motion. Such integrals of motion were identified to be the BLZ local integrals of motion. The identification was carried out by comparing the exact diagonalization of the Virasoro expressions with the spectrum derived form TBA. The eigenvalues (see tables 4–6) were found to be exactly the same and the eigenvectors, once expressed in terms of fermionic modes, turned out to be labelled by the same quantum numbers as the eigenvalues.

It has to be remarked that this is the first time that an exact diagonalization of all the BLZ local integrals of motion has been carried out in a particular case including all the excited states.

A more detailed analysis of the spectra obtained would surely be interesting and will be the subject of successive work.

Acknowledgments

Alessandro Nigro would like to thank Sergio Caracciolo, Giuseppe Mussardo, Antonio Rago, Paolo Grinza for their encouragement and support. Acknowledgement is due to Giovanni Feverati for his pointing the way into this beautiful field and for setting the $t = 0$ initial conditions. Thanks are due as well to Paul Pearce and Changrim Ahn for useful discussions and advice, and to Bortolo Mognetti and Matteo Cardella for showing a couple of useful tricks.
