Abstract

Using modern amplitude techniques we compute the leading classical and quantum corrections to the gravitational potential between two massive scalars induced by adding an $R^3$ term to Einstein gravity. We then study the scattering of massless scalars, photons and gravitons off a heavy scalar in the presence of the same $R^3$ deformation, and determine the bending angle in the three cases from the non-analytic component of the scattering amplitude. Similarly to the Einstein-Hilbert case, we find that the classical contribution to the bending angle is universal, but unlike that case, universality is preserved also by the first quantum correction. Finally we extend our analysis to include a deformation of the form $\Phi R^2$, where $\Phi$ is the dilaton, which arises in the low-energy effective action of the bosonic string in addition to the $R^3$ term, and compute its effect on the graviton bending.
1 Introduction

Modern on-shell methods [1,2] have proven extremely successful for the efficient computation of scattering amplitudes in gauge theory and gravity. By working with on-shell quantities one performs computations which are at every stage gauge invariant, yielding considerable conceptual and practical advantages.

Recently, amplitude methods have been applied to the computation of post-Newtonian and post-Minkowskian corrections in General Relativity (GR). Examples include the computation of the leading classical [3,4] and quantum [4] corrections at $O(G_N^2)$ to the Newton potential, confirming the earlier result of [5–7] based on Feynman diagrams, as well as the computation of the particle bending angle [8–11] (for other recent related computations see [12–21]). This is clearly a timely endeavour as LIGO necessitates computations in GR of unprecedented precision. Feynman diagram calculations have been employed for many years to extract relevant quantities for astrophysical processes. In this context, gravity is treated as an effective field theory [22], making it perfectly sensible to compute quantum corrections even if the theory is non-renormalisable. An alternative, systematic effective field theory treatment was introduced in [23], where the massive objects are treated as classical sources. The main focus for LIGO applications is to compute classical corrections, which, due to an interesting cancellation of $\hbar$ factors, are in fact obtained through loop calculations [24]. Notable efforts include the computations of the Newton potential at second [25,26], third [27–30], fourth [31–38] and fifth [39,40] post-Newtonian order, following the landmark computation at first post-Newtonian order [41]. Note also the effective one-body approach of [42], recently extended to incorporate the first and second post-Minkowskian corrections in [43,44], respectively.

In this paper we entertain the possibility of adding higher-derivative curvature terms to the Einstein-Hilbert (EH) theory that could arise either from string theory or other ultra-violet completions of gravity, and consider their effect on two quantities of relevance: the Newton potential, and the particle bending angle. We will focus on modifications to the three-graviton interactions, but exclude terms that modify the (tree-level) graviton propagator.\(^1\) Concretely, we will consider the action

$$S = -\frac{2}{\kappa^2} \int d^4x \sqrt{-g} \left[ R + \frac{\alpha' L}{48} I_1 \right], \quad \quad (1.1)$$

where $I_1 := R^\alpha_\mu_\nu R^\nu_\rho_\sigma R^\rho_\sigma_\alpha_\beta$, $\alpha'$ has dimension length squared, and $\kappa^2 = 32\pi G_N$, with $G_N$ being the Newton constant. The second term in the action is the only $R^3$-invariant that affects three- and four-graviton amplitudes [46,47]; in particular it produces three-graviton amplitudes with all-plus or all-minus helicities, in addition to the single-minus and single-plus tree amplitudes coming from the EH term. This term is also the two-loop counterterm for pure gravity, although in the following we use it as a tree-level deformation of the EH

\(^1\)A detailed discussion of other possible modifications affecting the propagator, in particular terms containing the square of the curvature, can be found in [45].
action. A number of amplitudes in this theory were computed in [47], also in the light of KLT relations [48] and the BCJ double-copy construction [49].

Note that we use this action as a low-energy effective theory, as the processes under consideration involve small energies and momenta, and is valid even if $\sqrt{\alpha'} \gg \kappa \sim \ell_{pl}$ as is the case in string theory. This possibility can enhance the effect of the $R^3$-invariant significantly compared to the more standard choice $\sqrt{\alpha'} \sim \kappa$. See [50] for a detailed analysis of causality constraints on the modifications of three-graviton interactions in the regime of large $\alpha'$ and consequences for possible ultraviolet completions of the effective gravity theory.

As anticipated, we will compute two quantities: first, the leading classical and quantum corrections to the Newton potential between two massive scalars, and second, the bending angle of massless particles of spin 0, 1 and 2 in the background of a heavy scalar. We extract these quantities from two-to-two scattering amplitudes at one loop which, as is well known in the literature [24], contains both classical and quantum corrections. Compared to the EH case we observe a further power suppression in the potentials consistent with the higher-derivative nature of the operator. The result for the classical contribution to the bending angle is expected to be spin-independent due to the equivalence principle, while this is not expected at the quantum level. Indeed in Einstein gravity this has been confirmed by [8–11]. Surprisingly, we find that also the first quantum correction to the bending angle is independent of the scattered particle in the presence of an $R^3$ coupling.

It is also interesting to consider the full low-energy effective action of the bosonic string, which has a coupling of the form $\Phi R^2$ in addition to the $R^3$ term in (1.1) (here $\Phi$ represents the dilaton). The only process that is affected is the graviton bending, and we will also compute the modification induced by this term.

Finally, the recent paper [51] computed corrections to the Newton potential due to a coupling of the form $R^\mu_\alpha_\beta R^\beta_\gamma_\nu_\sigma R^\sigma_\mu_\gamma_\alpha$. A natural combination to consider is $G_3 := I_1 - 2R^\mu_\alpha_\beta R^\beta_\gamma_\nu_\sigma R^\nu_\sigma_\gamma_\mu_\alpha$, which also appears in the low-energy effective action of the bosonic string, and is a topological invariant in six dimensions. It is also special because, as alluded to earlier, its three- and four-point graviton amplitudes vanish [46, 47]. For completeness of our presentation we will also briefly discuss the corresponding corrections to the Newton potential, which are non-vanishing. In addition, we will show that the $G_3$ interaction does not contribute to the bending of massless particles in the background of massive scalars.

The rest of the paper is organised as follows. In the next section we compute the classical and quantum correction to Newton’s potential to order $(\alpha' G_N)^2$. Section 3 is devoted to the calculation of the bending angle for particles of spin 0, 1 and 2 scattered off a heavy scalar. As anticipated, to order $(\alpha' G_N)^2$ we find that the classical and quantum bending angle corrections are independent of the spin of the scattered particles. The universality of the classical part is a consequence of the equivalence principle; that of the quantum part deserves further exploration. Also in that section we consider the new contribution to the graviton bending angle due to the inclusion of a coupling of the form $\Phi R^2$, which arises in the bosonic string theory. Section 4 contains our concluding remarks. We include in Appendix A the expressions of the integral functions and Fourier transforms used throughout the paper.
2 $R^3$ corrections to the gravitational potential

In this section we compute the leading classical and quantum corrections to the Newton potential induced by adding an $R^3$ coupling to the EH action (1.1).

Following [3,4] (see also earlier work in [5]), the potential can efficiently be obtained from the computation of the scattering amplitude of two scalar particles with masses $m_1$ and $m_2$. In the case of our interest, namely corrections due to the $R^3$ term in (1.1), it turns out that surprisingly the Born term is absent and the leading classical and quantum corrections arise at one loop. We will perform this calculation efficiently with well-established unitarity methods for amplitudes. The same approach will be used in the next section to determine the bending of a massless scalar by taking one of the two masses to zero.

In order to set the stage for the calculation we first discuss the kinematics of the $2 \to 2$ scattering process. To align with the notation used in subsequent sections we will choose the particle momenta so that $p_1^2 = p_2^2 = m_1^2, p_3^2 = p_4^2 = m_2^2$. We choose to parametrise the external momenta in the centre-of-mass frame as follows:

\begin{align}
\begin{array}{l}
p_1^\mu = -(E_1, \vec{p} - \vec{q}/2), \\
p_2^\mu = -(E_2, \vec{p} + \vec{q}/2), \\
p_3^\mu = (E_2, \vec{p} + \vec{q}/2), \\
p_4^\mu = (E_3, -\vec{p} - \vec{q}/2).
\end{array}
\end{align}

(2.1)

Furthermore, since we are considering elastic scattering we have

\begin{align}
E_1 = E_2 &= \sqrt{m_1^2 + \vec{p}^2 + \vec{q}^2/4}, \\
E_3 = E_4 &= \sqrt{m_2^2 + \vec{p}^2 + \vec{q}^2/4},
\end{align}

(2.2)

where $\vec{p} \cdot \vec{q} = 0$ due to momentum conservation. Notice that due to our all-outgoing convention for the external lines, the four-momenta $p_1$ and $p_4$, corresponding to the incoming particles, have an overall sign. Furthermore, our Mandelstam variables are defined as:

\begin{align}
s &:= (p_1 + p_2)^2 = -\vec{q}^2, & t &:= (p_1 + p_4)^2 = (E_1 + E_4)^2, & u &:= (p_1 + p_3)^2,
\end{align}

(2.3)

with $s + t + u = 2(m_1^2 + m_2^2)$. In this notation, the spacelike momentum transfer squared is given by $s$, while the centre of mass energy squared is given by $t$.

A comment is in order here. We will later be interested in computing the classical and one-loop quantum contributions to the potential\(^2\) arising from a (in this case leading) one-loop computation. This is obtained from the appropriately normalised amplitude by means of a Fourier transform in $\vec{q}$ [7]. Reinstating powers of $\hbar$, this Fourier transform involves a factor of $\exp(i\vec{q} \cdot \vec{r}/\hbar)$. It is important to be able to disentangle classical and quantum

---

\(^2\)To be precise, by this we mean the $\hbar^0$ and $\hbar^1$ terms of the potential. Due to the presence of massive particles the power of $\hbar$ is not related to the number of loops [24].
effects, and this can be achieved efficiently by replacing $\vec{q} = \hbar \vec{k}$ and then integrating over the wavevector, as carefully discussed in [17]. This in turn implies that we can suppress the term $\vec{q}^2$ in the expression of the energies in (2.2), which would produce $O(\hbar^2)$ corrections. Similarly, in the following we will suppress such corrections from expanding the Mandelstam variables $t$ or $u$.

Moving on to the unitarity-based calculation of the scattering process, we stress a crucial fact, namely that classical and quantum corrections to the potential are associated with terms in the amplitude that are non-analytic in the variable $s$ [22, 24] and, hence, have discontinuities in $s$. Therefore, it will suffice to consider two-particle cuts in the $s$-channel, see e.g. [3, 4] where modern on-shell methods were applied for the first time to this kind of problem. Furthermore, we only need to perform the cuts in four dimensions as discrepancies with $D$-dimensional cuts at one loop are related to rational, and hence, analytic terms.

![Figure 1: The two cut diagrams contributing to the leading $R^3$ correction to the gravitational scattering of two massive scalars. The two gravitons crossing the cut have both either positive or negative helicity and we have indicated this next to the dashed lines.](image)

The relevant channel to consider is therefore that associated with the momentum transfer in the scattering process. In this channel there are only two cut diagrams to consider, depicted in Figure 1. They are related by swapping the EH amplitude with the $R^3$ amplitude, which is equivalent to swapping $m_1$ and $m_2$ in the first diagram.

The cut calculation requires as input two types of two-scalar/two-graviton tree amplitudes. While the corresponding tree amplitudes in EH gravity with a minimally coupled scalar are well known, we need to derive the expression for the amplitudes due to the $R^3$ correction. Note that this interaction forces the two internal gravitons to have equal helicities, since the $R^3$ term can only produce three-graviton amplitudes with all helicities equal.

The well-known EH amplitude for the scattering of two scalars with mass $m_1$ and two gravitons is given by [52]

$$A(1^{\phi_{m_1}}, 2^{\phi_{m_1}}, \ell_1^-, \ell_2^-) = -\left(\frac{\kappa}{2}\right)^2 m_1^4 \frac{(\ell_1 \ell_2)}{[\ell_1 \ell_2]} \left[\frac{i}{(\ell_1 + p_1)^2 - m_1^2} + \frac{i}{(\ell_1 + p_2)^2 - m_1^2}\right]. \quad (2.4)$$

The amplitude with two scalars of mass $m_2$ and two gravitons produced by one insertion of
$R^3$ can easily be computed, with the result
\[
A_{R^3}(-\ell_1^{++}, -\ell_2^{++}, 3^{\phi_{m_2}}, 4^{\phi_{m_2}}) = \left(\frac{\kappa}{2}\right)^2 \left(\frac{\alpha'}{4}\right)^2 \frac{4i}{s_{12}} [\ell_1 \ell_2]^4 (\ell_1 \cdot p_3)(\ell_2 \cdot p_3). \tag{2.5}
\]

In order to arrive at (2.5) we had to evaluate a single Feynman diagram, and we used the expression of the three-point vertex with two scalars of mass $m$ and momenta $p_1$ and $p_2$ and one off-shell graviton$^3$

\[
V_{\phi_m \phi_m h}(p_1, p_2) = \left(\frac{\kappa}{2}\right) \left[ -\eta_{\mu\nu}(p_1 \cdot p_2 + m^2) + p_1^\mu p_2^\nu + p_2^\mu p_1^\nu \right], \tag{2.6}
\]

along with the three-point current $X_{R^3}^{\mu\nu}(1^{++}, 2^{++})$ with two on-shell, positive helicity gravitons and one off-shell graviton derived from the $R^3$ coupling, which is found to be

\[
X_{R^3}^{\mu\nu}(1^{++}, 2^{++}) = \left(\frac{\kappa}{2}\right) \left(\frac{\alpha'}{4}\right)^2 [12]^4 ([1|\mu|2][2|\nu|1] + \mu \leftrightarrow \nu). \tag{2.7}
\]

Note that this gives the well-known three positive-helicity graviton amplitude if we contract the free indices with the appropriate polarisation tensor,

\[
A_{R^3}(1^{++}, 2^{++}, 3^{++}) = -i \left(\frac{\kappa}{2}\right) \left(\frac{\alpha'}{4}\right)^2 ([12][23][31])^2. \tag{2.8}
\]

The two four-point amplitudes quoted above can now be combined to form the cut integrand in the $s$-channel. Note that in our conventions all external particle momenta $p_i$ are considered as outgoing. From the left-hand side of Figure 1 we get

\[
\mathcal{I}_{\phi_{m_1}, \phi_{m_2}}^{(1), \text{LHS}} \bigg|_{\text{s-cut}} = (2\mathcal{D}) 4m_1^4 s(\ell_1 \cdot p_3)(\ell_2 \cdot p_3) \left[ \frac{1}{(\ell_1 + p_1)^2 - m_1^2} + \frac{1}{(\ell_1 + p_2)^2 - m_1^2} \right], \tag{2.9}
\]

where we have multiplied by a factor of two due to the sum over internal helicities, we have introduced the universal combination of couplings

\[
\mathcal{D} = \left(\frac{\kappa}{2}\right)^4 \left(\frac{\alpha'}{4}\right)^2, \tag{2.10}
\]

and we have suppressed the ubiquitous two-particle phase space measure. The second cut

$^3$See for instance [53].
loop quantum) potential. The resulting expressions are:

As discussed after (2.3), we only need to keep the leading-order term in $s$ computation of the potential, namely those with discontinuities in the s-channel, and in the expression of the amplitudes presented below we will only include such integrals.

From the first diagram in Figure 1 we obtain

$$A_{\phi m_1 \phi m_2}^{(1), \text{LHS}} = c_3(m_1, m_2)I_3(s; m_1) + c_2(m_1, m_2)I_2(s),$$

(2.11)

where we have suppressed for the moment the overall factor $D$. The full Lorentz-invariant expressions of $c_2$ and $c_3$ are:

$$c_3(m_1, m_2) = \frac{4s^2m_1^4}{(4m_1^2 - s)^2} \left[ 2m_1^2 \left( m_1^4 - 2m_1^2 (m_2^2 + t) + (m_2^2 - t)^2 \right) 
+ s \left( -3m_1^4 + 2m_1^2m_2^2 + (m_2^2 - t)^2 \right) + s^2 (m_1^2 - m_2^2 + t) \right]$$

$$c_2(m_1, m_2) = \frac{2s^2m_1^4}{(4m_1^2 - s)^2} \left[ 6m_1^4 + 4m_1^2 (m_2^2 - 3t) + 6 (m_2^2 - t)^2 - 2s (2 (m_1^2 + m_2^2) - 3t) + s^2 \right].$$

(2.12)

As discussed after (2.3), we only need to keep the leading-order term in $s = -|\vec{q}|^2$ of (2.12). This is all what is needed in order to extract the full post-Minkowskian (classical plus one-loop quantum) potential. The resulting expressions are:

$$c_3(m_1, m_2) = \frac{(m_1s)^2}{2} \left[ (t - m_1^2 - m_2^2)^2 - 4m_1^2m_2^2 \right],$$

$$c_2(m_1, m_2) = \frac{s^2}{4} \left[ 3(t - m_1^2 - m_2^2)^2 - 4m_1^2m_2^2 \right].$$

(2.13)

For convenience we also quote the result for the post-Newtonian expansion, which requires further expanding for $|\vec{p}| \ll m_{1,2}$. In this non-relativistic limit, we have

$$c_3(m_1, m_2) \simeq (m_1s)^2 \left[ 2(m_1 + m_2)^2\vec{p}^2 \right],$$

$$c_2(m_1, m_2) \simeq s^2 \left[ 2m_1^2m_2^2 + 3(m_1 + m_2)^2\vec{p}^2 \right].$$

(2.14)

Curiously, in the static limit $\vec{p}^2 \rightarrow 0$ the leading term of $c_2$ is $O(s^3)$, while $c_3$ is of order $O(s^4)$ and hence further suppressed. The expressions for the bubble integral $I_2(s)$ and the massive triangle integral $I_3(s; m)$ are given in (A.1).

The classical contributions to the potential are identified with the non-analytic $1/\sqrt{-s}$
contributions, arising uniquely from the $I_3(s;m_{1,2})$ integral:

$$A^{(1),\text{cl}}_{\phi_{m_1},\phi_{m_2}} = -\frac{i}{32\sqrt{-s}} \left( \tilde{c}_3(m_1,m_2) \frac{m_1}{m_2} + \tilde{c}_3(m_2,m_1) \frac{m_2}{m_1} \right) = -\frac{is^2}{32\sqrt{-s}} \frac{m_1+m_2}{2} \left[ (t-m_1^2-m_2^2)^2 - 4m_1^2m_2^2 \right], \quad (2.15)$$

$$\simeq -\frac{is^2}{32\sqrt{-s}} (m_1+m_2) \left[ 2(m_1+m_2)^2 \bar{p}^2 \right],$$

where the middle line represents the full relativistic classical contribution, while the last line gives the small velocity approximation.\(^4\)

On the other hand the finite $\log(-s)$ terms from $I_2$ and $I_3$ are genuine quantum corrections:

$$A^{(1),\text{qu}}_{\phi_{m_1},\phi_{m_2}} = -\frac{i}{8\pi^2} s^2 \log(-s) \left[ (t-m_1^2-m_2^2)^2 - 2m_1^2m_2^2 \right]$$

$$\simeq -\frac{i}{4\pi^2} s^2 \log(-s) \left[ m_1^2m_2^2 + 2(m_1+m_2)^2 \bar{p}^2 \right]. \quad (2.16)$$

Finally, we extract the gravitational potential from the three-dimensional Fourier transform in $\vec{q}$ of the amplitude [7],

$$V(\vec{r},\vec{p}) = i \int \frac{d^3q}{(2\pi)^3} e^{i\vec{q}\cdot\vec{r}} \frac{A(\vec{q},\vec{p})}{4E_1E_4}, \quad (2.17)$$

with $\vec{q}$ and $\vec{p}$ related to the Mandelstam variables as described earlier in (2.3). We then get

$$V(\vec{r},\vec{p}) := V_{\text{cl}}(\vec{r},\vec{p}) + hV_{\text{qu}}(\vec{r},\vec{p}) = \int \frac{d^3q}{(2\pi)^3} e^{i\vec{q}\cdot\vec{r}} \left( v_{\text{cl}} + hv_{\text{qu}} \right), \quad (2.18)$$

with

$$v_{\text{cl}} = \frac{s^2}{\sqrt{-s}} \frac{m_1+m_2}{256E_1E_4} \left[ (t-m_1^2-m_2^2)^2 - 4m_1^2m_2^2 \right] \simeq \frac{s^2}{\sqrt{-s}} \frac{(m_1+m_2)^3 \bar{p}^2}{64m_1m_2},$$

$$v_{\text{qu}} = \frac{1}{32\pi^2} s^2 \log(-s) \left[ (t-m_1^2-m_2^2)^2 - 2m_1^2m_2^2 \right]$$

$$\simeq \frac{1}{32\pi^2} s^2 \log(-s) \left[ 2m_1m_2 + \bar{p}^2 \left( 8 + 3 \frac{m_1^2+m_2^2}{m_1m_2} \right) \right]. \quad (2.19)$$

Finally, we reinstate the overall factor $D = (\alpha'/4)^2(\kappa/2)^4$, introduce Newton’s constant $G_N := \kappa^2/(32\pi)$, and perform the Fourier transforms using (A.3) and (A.4). This gives our result for the leading classical and quantum corrections to Newton’s potential arising from

\(^4\)For the rest of this section we denote the non-relativistic limit of the full relativistic expression by $\simeq$. 8
the addition of an $R^3$ term to Einstein’s gravity:

\[ V_{cl}(\vec{r}, \vec{p}) = \frac{(\alpha'G_N)^2}{r^6} \frac{3(m_1 + m_2)}{16E_1E_4} \left[ (t - m_1^2 - m_2^2)^2 - 4m_1^2m_2^2 \right] \]

\[ \simeq \frac{(\alpha'G_N)^2}{r^6} \left[ \frac{3}{4} \frac{(m_1 + m_2)^3}{m_1m_2} \right] , \]

(2.20)

and

\[ V_{qu}(\vec{r}, \vec{p}) = \frac{(\alpha'G_N)^2}{r^7} \left\{ -\frac{15}{2\pi} \frac{[(t - m_1^2 - m_2^2)^2 - 2m_1^2m_2^2]}{E_1E_4} \right\} \]

\[ \simeq \frac{(\alpha'G_N)^2}{r^7} \left\{ -\frac{15}{2\pi} \frac{2m_1m_2 + \vec{p}^2 \left( 8 + 3\frac{m_1^2 + m_2^2}{m_1m_2} \right)}{m_1m_2} \right\} . \]

(2.21)

While we discussed so far the effects of the interaction $I_1 = R^\alpha_{\mu\nu} R^\mu_{\rho\sigma} R^\rho_{\sigma \alpha \beta}$, there exists a second independent contraction $R^\mu_{\nu \alpha \beta} R^\alpha_{\nu \gamma \sigma} R^\sigma_{\mu \gamma \alpha}$. Corrections to the Newton potential due to this interaction were recently studied in [51]. These two structures combine naturally into

\[ G_3 := I_1 - 2R^\mu_{\nu \alpha} R^\nu_{\beta \gamma \sigma} R^\sigma_{\mu \gamma \alpha} , \]

(2.22)

which appears in the low-energy effective action of the bosonic string (quoted later on in this paper in (3.21)). It is a topological invariant in six dimensions and its three- and four-point graviton amplitudes vanish [46,47]. For completeness we will now present a short discussion of the corrections to the Newton potential in the presence of the $G_3$ interaction.

The steps in the derivation of the potential are identical to the ones detailed above, but an important new ingredient is the two graviton/two scalar amplitude induced by the $G_3$-interaction with unit coefficient:

\[ A_{G_3}(1^{++}, 2^{++}, 3^{\phi m}, 4^{\phi m}) = -\frac{3!}{4} \left( \frac{\kappa}{2} \right)^4 [12]^4 (s + 2m^2) . \]

(2.23)

Importantly, this expression contains a contribution proportional to $m^2$ that leads to a qualitatively new term in the potential, while the term proportional to $s$ only gives a higher order in $\hbar$ correction which we will drop. Note also the absence of a collinear singularity in (2.23); indeed the three-point graviton amplitudes generated by $G_3$ vanish.

Feeding the amplitude in (2.23) in the cut computation as done earlier leads to the amplitude for the scattering of two massive scalars with masses $m_{1,2}$:

\[ \left( \frac{\kappa}{2} \right)^6 4(m_1m_2s)^2 \left[ m_1^2I_3(s, m_1) + m_1 \leftrightarrow m_2 \right] , \]

(2.24)

where as usual we only kept the leading term in $s$.

The coupling $G_3$ appears in the low-energy bosonic string effective action quoted later in (3.21) in the form $\mathcal{L}' = (-2/\kappa^2)\alpha'^2(G_3/24)$. For this particular interaction term, going
through the standard procedures one arrives at the following corrections to the potential:

\[
V'_{\mathcal C} = 12(\alpha'G_N)^2\frac{(m_1m_2)^2}{E_1E_4} \left( (m_1 + m_2)\frac{1}{r^6} - \frac{h}{r^7} \right),
\]  

(2.25)

where as usual \( G_N \) is Newton’s constant, and as before we have only written the classical contribution and the first quantum correction. Note one interesting difference between the classical correction arising from \( I_1 \) and \( G_3 \), namely that the latter does not vanish in the static limit \( |\vec{p}| \to 0 \).

Finally, we anticipate that there is no contribution to the bending of massless particles from massive scalars in the presence of the \( G_3 \) coupling, as discussed in the next sections.

3 Particle bending angle

In this section we compute the effect of the \( R^3 \) term to the bending of massless particles of spin 0, 1 and 2 in the presence of a heavy scalar particle of mass \( m \) using similar methods as in the previous section. We will compute the relevant scattering amplitudes of massless scalars, photons and gravitons off a massive scalar in Sections 3.1, 3.2 and 3.3, respectively, and then compute the bending angle in Section 3.4. Since we only consider elastic scattering, the helicity of the bent particle does not change in the process. Due to our convention that all particles have outgoing momenta, helicity conservation requires that the incoming massless particle has opposite helicity compared to the outgoing one.

Before starting it is useful to revisit the kinematics introduced in (2.1) in the situation where \( m_1 \to m \) and \( m_2 \to 0 \). In this case we have

\[
E_1 = E_2 = \sqrt{m^2 + |\vec{p}|^2 + \vec{q}^2/4},
\]

\[
E_3 = E_4 = \sqrt{\vec{p}^2 + \vec{q}^2/4} := \omega.
\]

(3.1)

We then find that \( s = -\vec{q}^2 \), as before, while \( t = (E_1 + E_4)^2 \simeq m(m+2\omega) \), and \( u = 2m^2 - s - t \). In order to extract the particle bending we work in a limit where

\[
- s = \vec{q}^2 \ll \omega^2 \ll m^2,
\]

(3.2)

which also implies \( ut - m^4 \simeq -(2m\omega)^2 \).

3.1 Scalar bending

The result for the bending of a massless scalar particle when it passes near a heavy scalar of mass \( m \) can be extracted from considering the right-hand side diagram in Figure 1, setting \( m_2 \to 0 \) and renaming \( m_1 \to m \). The left-hand side diagram simply vanishes in this limit.

\[\text{In the non-relativistic limit, one can approximate } (m_1m_2)^2/(E_1E_4) \to m_1m_2 - |\vec{p}|^2 (m_1^2 + m_2^2)/(2m_1m_2).\]
Doing so, and working in the limit (3.2), we arrive at the simple result

\[ A_{\phi}^{(1)} = D N_\phi \left[ 2(m^2 s \omega)^2 I_3(s; m) + 3(m s \omega)^2 I_2(s) \right], \quad (3.3) \]

where \( N_\phi = 1 \) is introduced only in order to then compare with the photon and graviton bending results in (3.11) and (3.16). As before, we have included a factor of two from summing over internal helicities. The expressions for the integral functions can be found in Appendix A.

It is interesting to compare our result to the corresponding result for scalar bending in Einstein gravity, Eq. (10) of [8]. Our result contains two more powers of \( s \), as expected from working with an \( R^3 \) interaction, which contains four more derivatives with respect to the EH action. As we will see later in (3.11) and (3.16), we will arrive at a result for the particle bending which is the same for scalars, photons and gravitons up to and including the first quantum correction. This universality of the quantum correction is unexpected – it is not a feature of Einstein gravity [8–11] – and deserves further investigation.

A final comment is in order. Due to the mass dependence in (2.23), there are no classical and \( \mathcal{O}(\hbar) \) corrections to the bending of massless scalars due to the \( G_3 \) coupling in (2.22) – this is clear from (2.23), where the \( m^2 \) term in the parenthesis vanishes while the second can be discarded because it induces corrections of \( \mathcal{O}(\hbar^2) \).

### 3.2 Photon bending

The cut diagram to compute in this case is shown in Figure 2. The amplitudes entering the cut are

\[ A_{\phi\phi}(1^{+\phi}, 2^{+\phi}, \ell_1^{-}, \ell_2^{-}) = -\left( \frac{\kappa}{2} \right)^2 m^4 \frac{\langle \ell_1 \ell_2 \rangle^2}{(\ell_1 + p_1)^2 - m^2} + \frac{i}{(\ell_1 + p_2)^2 - m^2}, \quad (3.4) \]

while for the two-photon/two-graviton amplitude we have

\[ A_{R^3}(\ell_2^{-}, -\ell_1^{-}, 3^{+}, 4^{-}) = -i \left( \frac{\kappa}{2} \right)^2 \left( \frac{\alpha'}{4} \right)^2 \frac{[\ell_1 \ell_2]^4}{s_{12}} \langle 4|\ell_1|3 \rangle^2. \quad (3.5) \]

The latter amplitude can be derived by using the expression of the minimal two-photon/one graviton coupling (see for instance Section (3.2) of [53]), which for the required helicities simplifies to

\[ V^{\mu\nu}(1^{+}, 2^{-}) = \begin{array}{c}
   \text{2}^{-} \\
   \text{1}^{+}
\end{array} \begin{array}{c}
   \text{\mu\nu} \\
   \text{\textbar}
\end{array} = -i \left( \frac{\kappa}{2} \right)^2 \langle 2|\mu|1 \rangle \langle 2|\nu|1 \rangle. \quad (3.6) \]
Contracting this with the already derived current (2.7) with two same-helicity gravitons and an additional off-shell graviton via the standard de Donder propagator leads to (3.5).

Using (3.4) and (3.5) we arrive at the following expression for the cut integrand

\[ I^{(1)}_{\gamma} \bigg|_{s\text{-cut}} = -2 D s m^4 \langle 4| \ell_1 |3 \rangle^2 \left[ \frac{1}{(\ell_1 + p_1)^2 - m^2} + \frac{1}{(\ell_1 + p_2)^2 - m^2} \right] , \]  

(3.7)
corresponding to the cut diagram in Figure 2. We have also included a factor of two from summing over the two possible internal helicity assignments.

Figure 2: The cut diagram contributing to the leading \( R^3 \) correction to gravitational scattering of a photon (wavy lines) off a massive scalar (double lines).

Reductions can be performed using the identity

\[ \langle 4| \ell_1 |3 \rangle = \frac{\text{Tr}(4 \ell_1 3 1)}{\langle 3| 2 |4 \rangle} , \]  

(3.8)
so that the integrand taken off the cut becomes

\[ I^{(1)}_{\gamma} = D^{8} m^4 s_{12} \left[ L^2 + E^2 \right] \left[ \frac{1}{(\ell_1 + p_1)^2 - m^2} + \frac{1}{(\ell_1 + p_2)^2 - m^2} \right] \frac{1}{L_1^2} \frac{1}{L_2^2} , \]  

(3.9)
where

\[ L := (p_1 p_3)(p_4 \ell_1) - (p_3 p_4)(p_1 \ell_1) + (p_4 p_1)(p_3 \ell_1) , \]
\[ E^2 := -[\epsilon(p_4 \ell_1 p_3 p_1)]^2 = \det M , \]  

(3.10)
and \( M \) is the matrix whose entries are the scalar products of the momenta in the \( \epsilon \) symbol. In going from (3.7) to (3.9) we have also dropped terms linear in the Levi-Civita symbol, which vanish upon integration. After performing the tensor reduction, keeping only terms with an \( s \)-channel discontinuity and dominant in the limit (3.2), we arrive at the simple result

\[ A^{(1)}_{\gamma} = D N_{\gamma} \left[ 2(m^2 s \omega)^2 I_3(s; m) + 3(m s \omega)^2 I_2(s) \right] , \]  

(3.11)
where \( N_{\gamma} := [(2 m \omega)/\langle 3| 2 |4 \rangle]^2 \). Note that \( |\langle 3| 2 |4 \rangle|^2 = -ut + m^4 \to (2m \omega)^2 \) in the low-energy
limit (3.2). As observed in [8], in this limit $N_\gamma$ is a phase that does not affect the potential and bending to be derived in Section 3.4.

Comparing our result to that of light bending in Einstein gravity obtained in [8], we see that our result is suppressed by two powers of $s$ compared to theirs, as expected from working with an $R^3$ interaction. Furthermore, we see that the term in square brackets in (3.11) is identical to the corresponding term in (3.3). This is true for the classical term (the massive triangle), as expected from the equivalence principle, but also for the first quantum correction (the bubble contribution).

Finally, in the presence of a $G_3$ interaction the tree-level amplitude on the right-hand side of Figure 2 vanishes, that is $A_{G_3}(-\ell_2^+, -\ell_1^+, 3^+, 4^-) = 0$, hence there is no photon bending produced by this interaction.

### 3.3 Graviton bending

The relevant cut diagram is depicted in Figure 3. The tree-level amplitudes entering this cut are given by

$$A(1^{\phi_m}, 2^{\phi_m}, \ell_1^-, \ell_2^-) = -\frac{\kappa^2}{2} m_4 \frac{(\ell_1 \cdot \ell_2)^2}{(\ell_1 + p_1)^2 - m^2} \left[ \frac{i}{(\ell_1 + p_1)^2 - m^2} + \frac{i}{(\ell_1 + p_2)^2 - m^2} \right],$$

while the amplitude in the $R^3$-deformed theory with two scalars and two gravitons is [47]

$$A_{R^3}(-\ell_2^+, -\ell_1^+, 3^+, 4^-) = -i \frac{\kappa^2}{2} \left( \frac{\alpha'}{4} \right)^2 \frac{(4 \ell_2 | \ell_2 3 \rangle \langle 3 4 \rangle)^2}{(\ell_2 \cdot \ell_1)(\ell_1 3 \rangle \langle 3 \ell_2)}.$$

Using these ingredients, one quickly arrives at the following form for the $s$-cut:

$$\mathcal{I}_h^{(1)} \bigg|_{s\text{-cut}} = -(2D)m^4 \langle 4| \ell_1 | 3 \rangle^4 \left[ \frac{1}{(\ell_1 + p_1)^2 - m^2} + \frac{1}{(\ell_1 + p_2)^2 - m^2} \right] \left[ \frac{1}{(\ell_1 - p_3)^2} + \frac{1}{(\ell_1 - p_4)^2} \right].$$
corresponding to four box topologies. The factor of two comes, as usual, from summing over internal helicities. Using (3.8) we can recast this as

\[
\mathcal{I}_h^{(1)} = (2\mathcal{D}) \left( \frac{2m}{\langle 3|2|4\rangle} \right)^4 \left[ L^4 + E^4 + 6L^2E^2 \right] \frac{1}{(\ell_1 + p_1)^2 - m^2} + \frac{1}{(\ell_1 + p_2)^2 - m^2} \left[ \frac{1}{(\ell_1 - p_3)^2} + \frac{1}{(\ell_1 - p_4)^2} \right] \frac{1}{\ell_1^2} \frac{1}{\ell_2^2}.
\] (3.15)

Following similar steps as in the previous case, and in particular keeping only the leading terms in the limit (3.2) we arrive at the result for the one-loop amplitude

\[
A_h^{(1)} = \mathcal{D} N_h \left[ 2(ms)^4 \left( I_4(s, t; m) + I_4(s, u; m) \right) + 2(m^2 s\omega)^2 I_3(s; m) + 3(ms\omega)^2 I_2(s) \right].
\] (3.16)

where \( N_h := (\langle 2m\omega \rangle/\langle 3|2|4\rangle)^4 = N_2^2 \). A few comments on this result are in order.

1. Compared to the graviton bending result in Einstein gravity [11], the triangle and bubble contributions are suppressed by a factor of \( s^2 \), as expected from having four more derivatives compared to the Einstein-Hilbert action.

2. The box contribution \( I_4(s, t; m) + I_4(s, u; m) \) is purely imaginary (see (A.1)) and also appears (with a different coefficient) in the corresponding computation in the Einstein-Hilbert case [8, 11]. It contributes an overall phase to the amplitude, and therefore will be dropped.

3. The result of the integral reduction, once we drop the box term, is exactly the same as we found for the scalar and photon case in (3.3) and (3.11).

4. We also note that since all four-point graviton amplitudes do not receive contribution from the \( G_3 \) interaction [46,47], graviton bending is not affected by this interaction.

### 3.4 From the amplitude to the potential and the bending angle

Next we derive the potential, from which we can infer the bending angle. The potential is defined as in (2.17), where now, using (3.1), we have \( 4E_1E_4 \rightarrow 4m\omega \). As in (2.18) we decompose the potential into its classical and quantum contributions in momentum space:

\[
v_{\text{cl}} + hv_{\text{qu}} = \mathcal{D} m^2 \omega \frac{s^2}{64 \sqrt{-s}} + h \mathcal{D} \frac{m\omega}{16\pi^2} s^2 \log(-s).
\] (3.17)

Performing the Fourier transforms using the results in Appendix A we get

\[
V_{\text{cl}}(\vec{r}, \vec{p}) = (\alpha'G_N)^2 \frac{3m^2\omega}{4\pi^6}, \quad V_{\text{qu}}(\vec{r}, \vec{p}) = - (\alpha'G_N)^2 \frac{15m\omega}{\pi^3 r}. \] (3.18)
The bending angle can then be computed using the semiclassical formula [56]

$$\theta = -b \frac{\omega}{\omega} \int_{-\infty}^{+\infty} du \frac{V'(b\sqrt{1+u^2})}{\sqrt{1+u^2}} ,$$

(3.19)

where $b$ is the impact parameter, with the result

$$\theta = (\alpha' G_N)^2 \frac{3}{32} \left( 15 \pi \frac{m^2}{b^6} - \hbar \frac{1024}{\pi} \frac{m}{b^7} \right) .$$

(3.20)

We can compare this result to that obtained for scalars and photons [8], and gravitons [11] in Einstein gravity. In those cases, the classical contribution is universal, as expected as a consequence of the equivalence principle, but the quantum contribution differs for different particles. In our case, both classical and quantum contributions are independent of the particle considered, and (3.20) is the bending angle for scalar, photon and gravitons. It should be noted that the universality of the one-loop quantum correction is unexpected, and would clearly be interesting to confirm or disprove it by higher-loop computations. We also note that our result for the bending angle is suppressed by a further factor of $1/b^4$ compared to the result of [8,11], as expected from our use of a higher-derivative interaction.

3.5 Graviton bending in the bosonic string theory

![Figure 4: The cut diagram contributing to the leading $(\Phi R^2)^2$ correction to gravitational scattering of a graviton (double wavy lines) off a massive scalar (double lines).](image)

The modified EH action (1.1) that we considered is known to be contained in the low-energy effective action of the bosonic string theory [57]

$$S_B = -\frac{2}{\kappa^2} \int d^4x \sqrt{-g} \left[ R - 2(\partial \Phi)^2 - \frac{1}{12} |dB|^2 + \frac{\alpha'}{4} e^{-2\Phi} G_2 + \alpha'' e^{-4\Phi} \left( \frac{1}{48} I_1 + \frac{1}{24} G_3 \right) + O(\alpha''^3) \right] .$$

(3.21)

In the definition of $S_B$ we have introduced the Gauss-Bonnet combination $G_2 = R^{\alpha\beta\mu\nu} R_{\alpha\beta\mu\nu} - 4 R^{\alpha\beta} R_{\alpha\beta} + R^2$, $I_1 = R^{\alpha\beta\mu\nu} R_{\mu\nu\sigma\rho} R^{\sigma\rho}_{\alpha\beta}$ and $G_3 = I_1 - 2 R^\mu_{\alpha\beta} R^{\beta\gamma\nu\sigma} R^\sigma_{\mu\gamma\alpha}.$

A natural question is whether the additional terms in the full effective action of the
bosonic string modify the computations presented so far in this paper. The extra terms do not introduce modifications of the three-graviton interaction \([46, 47]\), and do not affect the three- and four-point graviton amplitudes. However, the \(R_{\mu\nu\alpha\beta}R^{\delta\gamma\nu\sigma}R^\sigma_{\mu\gamma\delta}\) term modifies the scalar potential, as shown recently in \([51]\) and discussed at the end of Section 2.

In this section we focus on the corrections to the graviton bending arising from the \(G_2\) term. Here, a novel four-graviton amplitude with two positive and two negative helicity gravitons is produced due to two insertions of the \(\Phi R^2\) contained in the \(e^{-2\Phi}G_2\) term of (3.21). Note that the \(R^2\) term cannot produce a four graviton amplitude with this helicity configuration.

The cut to consider is displayed in Figure 4. The relevant amplitudes here are

\[
A(1^\phi m, 2^\phi m, \ell_1^{++}, \ell_2^{--}) = -\left(\frac{\kappa}{2}\right)^2 \frac{\langle\ell_2|2|\ell_1\rangle^4}{s_{12}^3} \frac{i}{(\ell_1 + p_1)^2 - m^2} + \frac{i}{(\ell_1 + p_2)^2 - m^2},
\]

while the \(\Phi R^2\) amplitude is given by the simple expression \([47]\)

\[
A_{\Phi R^2}(-\ell_1^{--}, 3^{++}, 4^{--}, -\ell_2^{++}) = -\left(\frac{\kappa}{2}\right)^2 \left(\frac{\alpha'}{4}\right)^2 \frac{2i}{(\ell_1 - p_4)^4} \langle\ell_1 4\rangle \langle3 4\rangle^4, \tag{3.23}
\]

which arises from two \(\Phi R^2\)-vertex insertions joined by a dilaton propagator. The one-loop integrand compatible with the \(s\)-channel cut becomes

\[
I_h^{(1)} = D \frac{2}{s_{12}^2} \left(\frac{4}{\langle 3|2\rangle^4}\right)^4 \left[ L^4 + 6L^2[p_2 \cdot (\ell_1 - p_4)]^2 E^2 + [p_2 \cdot (\ell_1 - p_4)]^4 E^4 \right] \\
\cdot \left[ \frac{1}{(\ell_1 + p_1)^2 - m^2} + \frac{1}{(\ell_1 + p_2)^2 - m^2} \right] \frac{1}{\ell_1^2 \ell_2^2},
\]

where

\[
L := (p_2\ell_1)[(p_2p_3)(p_4\ell_1) - (p_3p_4)(\ell_1p_2) + (p_3\ell_4)(p_2p_4)] \\
+ (p_2p_4)[(p_2p_3)(\ell_1p_4) - (p_3\ell_1)(p_2p_4) + (p_3p_4)(\ell_1p_2)] - m^2(p_3p_4)(\ell_1p_4),
\]

\[
E^2 := -[\epsilon(p_2p_3p_4\ell_1)]^2 = \det N,
\]

and \(N\) is the matrix whose entries are the scalar products of the momenta within the Levi-Civita symbol. Performing the reductions, and taking the limit (3.2), we obtain

\[
A_h^{(1)} = D N_h \left[ (4 m^2 \omega^2 s)(I_4(s, t; m) + I_4(s, u; m)) - 35(m^2 \omega^2 s) I_3(s; m) \\
+ 28(m \omega)^2 s I_3(s) + (m \omega)^2 \left( -\frac{251}{6} + \frac{3587}{90} \epsilon \right) I_2(s) \right],
\]

where \(N_h := \left(\frac{2m \omega}{\langle 3|2\rangle^4}\right) = N_s^2\).

Finally we compute the bending angle, following the same steps as in Section 3.4. As
before, we first compute the potential, from which we will then obtain the bending. The potential is defined in (2.17), where again, using (3.1), we have $4E_1E_4 \rightarrow 4m\omega$. It can be decomposed into a classical and quantum contribution in momentum space:

$$v_{cl} + \hbar v_{qu} = -D \frac{35 m^2 \omega}{128} \frac{s^2}{\sqrt{-s}} - \hbar \mathcal{D} \left[ \frac{89 m \omega}{24 \pi^2} s^2 \log(-s) + \frac{7 m \omega}{32 \pi^2} s^2 \log^2(-s) \right]. \tag{3.27}$$

Performing the Fourier transforms using results in Appendix A and reinstating couplings and the appropriate kinematic prefactor, we arrive at

$$V_{cl}(\vec{r}, \vec{p}) = -(\alpha' G_N)^2 \frac{105 m^2 \omega}{8r^6},$$

$$V_{qu}(\vec{r}, \vec{p}) = (\alpha' G_N)^2 \left\{ \frac{890 m \omega}{\pi r^7} - \frac{7 m \omega}{2 \pi} \frac{1}{r^7} \left[ 60 \log(r \mu e^\gamma) - 137 \right] \right\}. \tag{3.28}$$

Using again (3.19), we arrive at the final result for the bending angle in the presence of a $\Phi R^2$ coupling:

$$\theta = (\alpha' G_N)^2 \left\{ - \frac{1575 \pi m^2}{64} \frac{1}{b^6} + \hbar \frac{64}{\pi} \left[ -21 \log \left( b/(2r_0) \right) + 124 \right] \frac{m}{b^7} \right\}. \tag{3.29}$$

It is interesting to compare (3.29) with (3.20). We note that the classical contributions to these two angles have opposite signs, and the $\Phi R^2$ contribution is larger than the $R^3$ contribution by a factor of $\sim 15$. Similar comments apply to the quantum correction. Hence in the bosonic string the combined bending angle would be dominated by the $\Phi R^2$ contribution.

## 4 Closing comments

We wish to conclude with a summary of some open problems and possible future directions of our work, which clearly only touches on the tip of an iceberg of possible higher-derivative modifications that can be contemplated.

1. It would be interesting to consider particles coupled non-minimally to the graviton e.g. the photon coupled to the Riemann tensor as $\alpha \gamma \int d^4x \sqrt{-g} F \mu \nu F^{\alpha \beta} R_{\mu \nu \alpha \beta}$. The leading correction to the amplitude would then come from a single graviton-exchange diagram.

2. It would be interesting to understand the universality (i.e. spin-independence) of the quantum corrections to the particle bending. In pure gravity only the classical corrections are universal in consonance with the equivalence principle.

3. Can $\alpha'$ be made large enough, and consistent with known constraints, to produce effects that are comparable with PN$x$ correction from pure gravity, and for what $x$? Or in other words, can our results be used in conjunction with LIGO results or otherwise to put observational bounds on $\alpha'$?

A Integrals and Fourier transforms

The expression for the integral functions occurring in our calculations, expanded up to the relevant orders in $\epsilon$, and keeping only terms with an $s$-channel discontinuity, are:

\[
I_2(s) = \frac{ic\Gamma(-s)\epsilon}{\epsilon(1-2\epsilon)} \simeq \frac{i}{16\pi^2} \left[ \frac{1}{\epsilon} - \log(-s) \right],
\]

\[
I_3(s) = -\frac{ic\Gamma(-s)^{-1}\epsilon}{\epsilon^2} \simeq \frac{i}{16\pi^2} \left[ \frac{1}{\epsilon} \log(-s) \right] + \frac{1}{2\epsilon} \log^2(-s),
\]

\[
I_3(s;m) = -\frac{i}{32} \left[ \frac{1}{m\sqrt{-s}} + \frac{\log(-s/m^2)}{\pi^2m^2} \right] + O(\sqrt{s}),
\]

\[
I_4(s,t;m) + I_4(s,u;m) \simeq \frac{i}{16\pi s(m\omega)} \cdot i \left[ \frac{1}{\epsilon} - \log \left( -\frac{s}{m^2} \right) \right],
\]

where

\[
c_\Gamma = \frac{\Gamma(1+\epsilon)\Gamma^2(1-\epsilon)}{(4\pi)^2\epsilon \Gamma(1-2\epsilon)},
\]

and $f(\epsilon)$ is a kinematic-independent function that will contribute to any of the physical quantities computed in this paper as it gives rise to terms that vanish when Fourier transformed.

We also quote the relevant Fourier transforms used in the text:

\[
\int \frac{d^d q}{(2\pi)^d} e^{i\vec{q}\cdot\vec{r}} |\vec{q}|^\alpha = \left( \frac{2}{r} \right)^{d+\alpha} \frac{\Gamma \left( \frac{d+\alpha}{2} \right)}{(4\pi)^{d/2}\Gamma \left( -\frac{\alpha}{2} \right)},
\]

as well as

\[
\int \frac{d^3 q}{(2\pi)^3} e^{i\vec{q}\cdot\vec{r}} |\vec{q}|^4 \log(q^2) = -\frac{60}{\pi} \frac{1}{r^7},
\]

and

\[
\int \frac{d^3 q}{(2\pi)^3} e^{i\vec{q}\cdot\vec{r}} |\vec{q}|^4 \log^2 \left( \frac{q^2}{\mu^2} \right) = \frac{4}{\pi} \frac{1}{r^7} \left[ 60 \log(r/r_0) - 137 \right],
\]

where $r_0 := (\mu e^\gamma E)^{-1}$.
