Harish-Chandra Research Institute, Allahabad-211019, India

Quantum coherence is a key component of topical research on quantum resource theories and a primary facilitator for design and implementation of quantum technologies. However, the resourcefulness of quantum coherence is severely restricted by environmental noise, which is indicated by the loss of information in a quantum system, measured in terms of its purity. In this work, we derive the limits imposed by the mixedness of a quantum system on the amount of quantum coherence that it can possess. We obtain an analytical trade-off between the two quantities that upperbounds the maximum quantum coherence for fixed mixedness in a system. This gives rise to a class of quantum states, “maximally coherent mixed states”, whose coherence cannot be increased further under any purity-preserving operation. For the above class of states, quantum coherence and mixedness satisfy a complementarity relation, which is crucial to understand the interplay between a resource and noise in open quantum systems.

I. INTRODUCTION

Recent developments in modern science have shown that quantum coherence plays an important role in low temperature physics starting from the formulation of the basic laws of thermodynamics to work extraction [1–11]. Furthermore, it is a useful figure of merit in investigating nanoscale systems [12, 13] and understanding efficient energy transfer in complex biological systems [14–18]. In recent years, researchers have attempted to develop a framework to formalize the theory of quantum coherence within the realms of quantum information and quantum resource theories [19–25]. The formalism of quantum coherence as a resource [21] is based on a defined set of incoherent operations that are allowed and a set of freely available incoherent states. Within this framework, quantum coherence is a well-defined resource, which can be quantified in terms of functions or coherence monotones that satisfy certain characteristic conditions. Some of the better known measures of quantum coherence are those based on $L_1$ norm and relative entropy [21], and skew-information [23]. Incidentally, a recent work proves that all measures of entanglement can be artfully used to define a family of valid measures of quantum coherence [26].

Another significant aspect in the dynamics of quantum systems is the role of environmental noise and the unavoidable phenomenon of decoherence. It is known that decoherence is detrimental to the amount of information contained in a state, as measured by the purity of the state. To effectively characterize the role of decoherence in erasing information [27] one needs to quantify the purity or, its complementary property, the mixedness of the state. A faithful measure of mixedness is the normalized linear entropy [28]. From the perspective of resource theory of purity [29, 30], mixedness can be obtained as a complementary quantity to global information. Since, noise tends to increase the mixedness of a quantum system, it emerges as an intuitive parameter to understand decoherence. A natural question that arises is: How does important physical quantities in quantum information theory, such as entanglement [31], fare against mixedness of quantum systems? An interesting direction is to obtain the maximum amount of entanglement for a given mixedness, which leads to the notion of maximally entangled mixed states [32–36]. The amount of entanglement in such states cannot be increased further under any global unitary operation. Also, the form of the maximally entangled mixed states depends on the measures employed to quantify entanglement and mixedness in the system [35].

In our work, we investigate the limits imposed by mixedness of a quantum system on the amount of quantum coherence present in the system. We derive an analytical trade-off between the two quantities that allows us to upperbound the maximum coherence in a given mixed quantum state and vice-versa. Using the $L_1$ norm of coherence [21] as a measure of quantum coherence and normalized linear entropy [28] as a measure of mixedness, we prove that for a general $d$-dimensional quantum system the sum of the (scaled) squared coherence and the mixedness is always less than or equal to unity. This allows us to derive a class of quantum states, viz. “maximally coherent mixed states” (MCMS), that have maximal coherence, up to incoherent unitaries, for a fixed mixedness. These states are parametrized mixtures of a $d$-dimensional pure maximally coherent state and maximally mixed state. Interestingly, for different values of mixedness the analytical form of MCMS remains unchanged and, unlike maximally entangled mixed states, is not dependent on the choice of the measure of coherence and mixedness, as observed for $L_1$ norm and relative entropy of coherence. The obtained analytical results, show an important trade-off between a relevant quantum resource and noise in open quantum systems and a complementary behavior between coherence and mixedness in the class of MCMS, which may be crucial from the perspective of quantum resource theories and thermodynamics.

The paper is organized as follows. In Sec. II, we briefly discuss the quantification of coherence and mixedness. In Sec. III, we theorize the trade-off between coherence and mixedness in $d$-dimensional systems. In Sec. IV, we define a class of maximally coherent mixed states that satisfy a complementarity relation between coherence and mixedness. In Sec. V, we investigate the allowed set of transformations within classes of fixed coherence or mixedness. We conclude with a discussion of the main results in Sec. VI.
II. QUANTIFYING COHERENCE AND MIXEDNESS

We briefly introduce the formalism to characterize and quantify coherence and mixedness of quantum systems, which are the two central quantities in our present investigation.

Quantum coherence—Quantum coherence, an essential feature of quantum mechanics arising from the superposition principle, is inherently a basis dependent quantity. Therefore, any quantitative measure of it must depend on a reference basis. The framework, to quantify coherence in the context of quantum information theory, is based on the characterization of a set of incoherent states, denoted by $\mathcal{I}$ and incoherent operations $\Lambda^I$ [21]. For a given reference basis $\{|i\rangle\}$, all the states of the form $\rho_I = \sum_i d_i \langle i | i \rangle$, where $d_i \geq 0$ and $\sum_i d_i = 1$, form a set, $\mathcal{I}$, of incoherent states. Incoherent operations $\Lambda^I$, are defined as completely positive trace preserving (CPTP) maps, which map the set of incoherent states onto itself, i.e., $\Lambda^I(|i\rangle) = |i\rangle$. Under the set of operations $\Lambda^I$ and the free incoherent states $\mathcal{I}$, quantum coherence is a valid resource, that can be quantified. A function, $C(\rho)$, is a bona fide measure of quantum coherence of the state, $\rho$, if it satisfies the following conditions [21]: (1) $C(\rho) = 0$ iff $\rho \in \mathcal{I}$. (2) $C(\rho)$ is non increasing under the incoherent operations, i.e., $C(\Lambda_1[\rho]) \leq C(\rho)$. (3) $C(\rho)$ decreases on an average under the selective incoherent operations, i.e., $\frac{1}{k} \sum_k p_k C(\rho_k) \leq C(\rho)$, where $\rho_k = M_k \rho M_k^\dagger$, $p_k = \text{Tr}(M_k \rho M_k^\dagger)$ and $M_k$ are the Kraus elements of an incoherent channel. (4) $C(\rho)$ is convex in its arguments, i.e., $C(\sum_k p_k \rho_k) \leq \sum_k p_k C(\rho_k)$. One may note that the conditions (3) and (4) together imply condition (2).

Measures that satisfy the above conditions, include $l_1$ norm and relative entropy of coherence [21] and the skew information [23]. Generic monotones of quantum coherence can also be derived using entanglement monotones that satisfy the above conditions [26]. In this work, we shall mainly be focused on the $l_1$ norm of coherence. For a quantum state $\rho$ and the reference basis $\{|i\rangle\}$, the $l_1$ norm of coherence is given by

$$C_{l_1}(\rho) = \sum_{i \neq j} |\rho_{ij}|,$$

where $\rho_{ij} = \langle i | \rho | j \rangle$. Another measure of coherence is the relative entropy of coherence, which is given by $C_r(\rho) = S(\rho_d) - S(\rho)$, where $S(\rho) = -\text{Tr}(\rho \ln \rho)$, is the von Neumann entropy and $\rho_d = \sum_i \langle i | \rho | i \rangle |i\rangle \langle i|$. It is important to note that quantum coherence, by definition, is not invariant under general unitary operation but does remain unchanged under incoherent unitaries. Furthermore, the maximally coherent pure state is defined by $|\phi_d\rangle = \frac{1}{\sqrt{d}} \sum_{i=0}^{d-1} |i\rangle$, for which $C(\rho) = 1$.

Mixedness—For every quantum state, the ubiquitous interaction with environment or decoherence affects its purity. Noise introduces mixedness in the quantum system leading to loss of information, and hence, its characterization is an important task in quantum information protocols. The mixedness, which represents nothing but the disorder in the system, can be quantified in terms of entropic functionals, such as linear and von Neumann entropy of the quantum state. For an arbitrary $d$-dimensional state, the mixedness, based on normalized linear entropy [28], is given as

$$M(\rho) = \frac{d}{d-1} \left( 1 - \text{Tr}(\rho^2) \right).$$

Therefore, for each quantum system, mixedness varies between 0 and 1, i.e. $0 \leq M(\rho) \leq 1$. Furthermore, since $\text{Tr}(\rho^2)$ describes the purity of quantum system, mixedness expectedly emerges as a complementary quantity to the purity of the given quantum state. The other operational measure of mixedness of a quantum state $\rho$ is the von Neumann entropy, $S(\rho) = -\text{Tr}(\rho \ln \rho)$.

III. TRADE-OFF BETWEEN QUANTUM COHERENCE AND MIXEDNESS

In this section, we investigate the restrictions imposed by the mixedness of a system on the maximal amount of quantum coherence. We prove that there exists an analytical trade-off between the two quantities and for a fixed amount of mixedness the maximal amount of coherence is limited. The results allow us to derive a class of states that are the most resourceful, in terms of quantum coherence, under a fixed amount of noise, characterized by its mixedness.

The important trade-off between quantum coherence, as quantified by the $l_1$ norm, and mixedness, in terms of the normalized linear entropy, is captured by the following theorem.

Theorem 1. For any arbitrary quantum system, $\rho$, in $d$-dimensions, the amount of quantum coherence, $C(\rho)$, in the state is restricted by the amount of mixedness, $M(\rho)$, through the inequality

$$\frac{C^2(\rho)}{(d-1)^2} + M(\rho) \leq 1.$$

Proof. Using the parametric form of an arbitrary density matrix, the state of a $d$-dimensional quantum system can be written in terms of the generators, $\hat{A}_i$, of $SU(d)$ [40–44], as

$$\rho = \frac{1}{d} + \frac{d^2-1}{2} \sum_{i=1}^d x_i \hat{A}_i,$$

where $x_i = \text{Tr}[\rho \hat{A}_i^\dagger \hat{A}_i]$. The condition of positivity can be stated in terms of the coefficients of the characteristic equation for the density matrix $\rho$. Specifically, the Eq. (4) is positive iff all the coefficients of the polynomial $\sum_{i=0}^d (-1)^i A_i x^{d-i} = 0$, $A_i \geq 0$ for $1 \leq i \leq d$ ($A_0 = 1$). This criterion can be verified simply by calculating traces of various powers of $\rho$ [43, 44]. The generators $\hat{A}_i$ ($i = 1, 2, \ldots, d^2 - 1$) satisfy (1) $\hat{A}_i = \hat{A}_i^\dagger$. (2) $\text{Tr}(\hat{A}_i) = 0$, and (3) $\text{Tr}(\hat{A}_i \hat{A}_j) = 2\delta_{ij}$. These generators are defined by the structure constants $f_{ijk}$ (a completely antisymmetric tensor) and $g_{ijk}$ (a completely symmetric tensor), of Lie algebra $su(d)$ [42, 43]. The generators can be conveniently written as $\{\hat{A}_i\}_{i=1}^{d^2-1} = \{\hat{u}_{jk}, \hat{v}_{jk}, \hat{w}_l\}$. Here $\hat{u}_{jk} = \langle j | \langle k | + | k | \langle j |$, $\hat{v}_{jk} = -i \langle j | \langle k | - | k | \langle j |$, and $\hat{w}_l = \sqrt{\frac{2}{l+1}} \sum_{j=1}^l \langle j | | j \rangle = | j \rangle - | j \rangle - 1 + | l \rangle + 1$.
where \( j < k \) with \( j,k = 1,2,\ldots,d \) and \( l = 1,2,\ldots(d-1) \). The generators can be labelled as \( \{ \hat{A}_1, \ldots, \hat{A}_{d^2-d}, \hat{A}_{d^2-d+1}, \ldots, \hat{A}_{d(d-1)+1}, \ldots, \hat{A}_{d^2-1} \} = \{ \hat{u}_{1}, \ldots, \hat{u}_{(d-1)d}, \hat{v}_{1}, \ldots, \hat{v}_{(d-1)d}, \hat{w}_{1}, \ldots, \hat{w}_{(d-1)d} \} \).

The \( l \) norm of coherence of a \( d \)-dimensional system, given by Eq. (4), can be written as

\[
C_l(\rho) = \sum_{m,n=1}^{d} |\langle m | \hat{A} | n \rangle| \frac{d^2-1}{2} \sqrt{x_i^2 + x_j^2}.
\]

Furthermore, the mixedness is given by

\[
M(\rho) = \frac{d}{d-1} (1 - Tr \rho^2) = 1 - \frac{d}{2(d-1)} \sum_{i=1}^{d^2-1} x_i^2.
\]

Using the expressions for \( C_l(\rho) \) and \( M(\rho) \), we obtain

\[
C_l^2(\rho) + M(\rho)
= \frac{1}{d-1} \left( \sum_{i=1}^{d^2-1} x_i^2 \right)^2 + \frac{d}{2(d-1)} \sum_{i=1}^{d^2-1} x_i^2
= 1 - \frac{1}{d-1} \sum_{i=1}^{d^2-1} x_i^2 - \frac{(d^2-d)/2 - 1}{(d-1)^2} \sum_{i=d^2-d}^{d^2-1} x_i^2
+ \frac{1}{d-1} \left( \sum_{i=1}^{d^2-1} x_i^2 \right)^2 - \frac{(d^2-d)}{2} \sum_{i=1}^{d^2-1} x_i^2
\leq 1 - \frac{d}{2(d-1)} \sum_{i=d^2-d}^{d^2-1} x_i^2,
\]

where, in the last step, we have used the inequality \( 2 \sqrt{xy} \leq (x+y) \). Since the \( \frac{d}{2(d-1)} \sum_{i=d^2-d}^{d^2-1} x_i^2 \geq 0 \), we have \( C_l^2(\rho) + M(\rho) \leq 1 \), which concludes our proof. \( \square \)

Theorem 1 proves that the scaled coherence, \( \frac{C_l(\rho)}{(d-1)^2} \), of a quantum system with mixedness \( M(\rho) \), is bounded to a region below the parabola \( \frac{C_l^2(\rho)}{(d-1)^2} + M(\rho) = 1 \) (see Fig. 1). The quantum states with (scaled) quantum coherence that lie on the parabola are the maximally coherent states corresponding to a fixed mixedness and vice-versa. The trade-off obtained between coherence and mixedness can be neatly presented for a qubit system. Let us consider an arbitrary single-qubit density matrix of the form

\[
\rho = \begin{pmatrix} a & c \\ c^* & 1 - a \end{pmatrix}.
\]

The eigenvalues of the above density matrix are given by \( \lambda_\pm = \frac{1}{2} \left( 1 \pm \sqrt{1 - 4|a(1-a) - 4|c|^2|} \right) \). The positivity and Hermiticity of the density matrix implies that \( 0 \leq a(1-a) - 4|c|^2 \leq 1/4 \). Now, the mixedness of the state \( \rho \) is given by \( M(\rho) = 4a(1-a) - 4|c|^2 \). The \( l_1 \) norm of coherence is \( C_l(\rho) = 2|c| \). Using the expressions of coherence and mixedness, we obtain \( C_l^2(\rho) + M(\rho) = 4a(1-a) \). Since, \( 4a(1-a) \leq 1 \), we have \( C_l^2(\rho) + M(\rho) \leq 1 \), with the equality holding if and only if \( a = 1/2 \).

From Theorem 1, we know that the maximum coherence permissible in an arbitrary quantum state with a fixed mixedness, are the values that lie on the parabola \( \frac{C_l^2(\rho)}{(d-1)^2} + M(\rho) = 1 \). The same holds for the maximum mixedness allowed in a quantum state with fixed coherence (see Fig. 1). A natural question arises: What are the quantum states that correspond to the maximal coherence and satisfy the equality in Eq. (3)? The above question is addressed in the following section.

**IV. MAXIMALLY COHESIVE MIXED STATES AND COMPLEMENTARITY**

Let us find the quantum states with maximal coherence for a fixed amount of mixedness, say, \( M_f \). For this, we need to maximize the coherence under the constraint that the mixedness \( M_f \) is invariant. Here we provide the form of maximally coherent mixed state for a general \( d \)-dimensional system.

**Theorem 2.** An arbitrary \( d \)-dimensional quantum system with maximal coherence for a fixed mixedness, \( M_f \), up to incoherent unitaries, is of the following form

\[
\rho_m = 1 - \frac{p}{d} |\psi_d\rangle \langle \psi_d|,
\]

where \( |\psi_d\rangle = \frac{1}{\sqrt{d}} \sum_{i=1}^{d} |i\rangle \), is the maximally coherent state in the computational basis, \( \mathbb{1}_{d \times d} \) is the \( d \)-dimensional identity operator and the mixedness, in terms of normalized linear entropy, is equal to, \( M_f = 1 - p^2 \).

**Proof.** Using the parametric form of the density matrix given in Eq. (4), the expressions for coherence and mixedness of any \( d \)-dimensional system was obtained in Eqs. (5) and (6). To prove the above theorem, we seek the maximal coherence for a fixed mixedness, say \( M_f \), i.e. we maximize the function \( C_l(\rho) \), under the constraint

\[
M_f = 1 - \frac{d}{2(d-1)} \sum_{i=1}^{d^2-1} x_i^2.
\]

Hence, we need to maximize the Lagrange function

\[
L = \sum_{i=1}^{k^2} x_i^2 + x_j^2/(2a_i) + \lambda \left( 1 - \frac{d}{2(d-1)} \sum_{i=1}^{k^2} x_i^2 - M_f \right),
\]

where \( D = d^2 - d \) and \( \lambda \) is the Lagrange multiplier. The stationary points, \( \{ x_j \} \), of \( C_l(\rho) \) imply vanishing of

\[
\frac{\partial L}{\partial x_j}\bigg|_{\{ x_j \}} = \begin{cases} \frac{x_j}{\sqrt{x_j^2 + x_j^{2d-2}}} - \frac{d-1}{d} x_j, & \text{for } j \leq D/2 \\ -\frac{d-1}{d} x_j, & \text{for } j > D \end{cases}.
\]

Therefore, we have $x_j' = 0$ for all $j > D$ and $\sqrt{x_j'^2 + x_{j+D/2}^2} = \frac{d-1}{ad}$ for $j \leq D/2$. This implies that

$$x_1'^2 + x_{1+D/2}^2 = x_2'^2 + x_{2+D/2}^2 = \ldots = x_D'^2 + x_{D/2}^2 = \left(\frac{d-1}{ad}\right)^2.$$  

Putting these values of $x_j'$s in the constraint equation Eq. (10) we get, $\lambda = (d-1)/(2\sqrt{(1-M_f)})$. The positive value of $\lambda$ is chosen because negative value leads to negative coherence, which is not desired. The value of coherence for the stationary states, is given by

$$C_1(\rho) = \sum_{j=1}^{D/2} \sqrt{x_j'^2 + x_{j+D/2}^2} = (d-1) \sqrt{1-M_f}.$$  

This is the maximal value of coherence that a state can have for a fixed value of mixedness $M_f$. Therefore, the states with $x_j'^2 + x_{j+D/2}^2 = 4/(1-M_f)/d^2$ for $j \leq D/2$ and $x_j = 0$ for $j > D$, are the states that have maximum coherence for a given mixedness $M_f$. These states can be written as

$$\rho_m = \frac{I}{d} + \frac{R}{2} \sum_{j=1}^{D/2} \left( \cos \theta_i \hat{A}_i + \sin \theta_i \hat{A}_{i+D/2} \right),$$  

where $R = \frac{2\sqrt{(1-M_f)}}{d}$ and $\theta_i = \tan^{-1}(x_{i+D/2}/x_i)$. We observe that the diagonal part of these states is maximally mixed and the points, $\{x_i, x_{i+D/2}\}_{i=1}^{D/2}$, that define the off-diagonal elements, lie on the circle of radius $R$ in the real $(x_i, x_{i+D/2})$-plane. An equivalent form of above states can be written, by identifying $\{\theta_1, \ldots, \theta_{d-1}, \theta_d, \theta_{d-1}, \ldots, \theta_1\}$, as

$$\rho_m = \frac{I}{d} + \frac{R}{2} \sum_{i=1}^{d} \sum_{i<j} \left( e^{i\phi_{ij}} |i\rangle\langle j| + e^{-i\phi_{ij}} |j\rangle\langle i| \right).$$  

Now, the phases appearing in the off diagonal components can be removed by applying an incoherent unitary of the form $U = \sum_{n=1}^{2^d} e^{i\psi_n} |n\rangle\langle n|$, which keeps the coherence invariant. To this end by choosing $\phi_{ij} = \gamma_i - \gamma_j$ we get,

$$\rho_m = \frac{I}{d} + \frac{R}{2} \sum_{i=1}^{d} \sum_{i<j} |i\rangle\langle j| + |j\rangle\langle i|. $$  

Now, setting $R = 2p/d$, we obtain the state given in Eq. (9). Therefore, up to incoherent unitary transformations, the states with maximal coherence for a fixed mixedness are those that take the form given by Eq. (9). This completes the proof. ☐

For a single-qubit quantum system, the proof can be mathematically elaborated. For the density matrix, given in Eq. (8), we need to maximize the coherence under the constraint that, $M_f = 4a(1-a) - 4|c|^2$, is invariant. Hence, we need to maximize, $C_1(\rho) = 2|c| + \lambda(4a(1-a) - 4|c|^2 - M_f)$, where $\lambda$ is the Lagrange multiplier. Upon optimization, the stationary points are given by $a = 1/2$ and $|c| = 1/(4\lambda)$. Using constraint equation, we get $\lambda = \pm 1/(2\sqrt{1-M_f})$. Choosing the positive value of $\lambda$, we obtain $|c| = \sqrt{1-M_f}/2$. Thus, the maximum value of coherence is equal to, $C_1(\rho) = \sqrt{1-M_f}$ and the corresponding states, are given by

$$\rho_m(\phi) = \frac{1}{2} \left( \frac{1}{\sqrt{1-M_f} \exp[i\phi]} \right) \left( \frac{1}{\sqrt{1-M_f}} \right),$$  

where $\phi$ is an arbitrary phase. The phase can be removed through incoherent unitaries which keeps the coherence invariant. The density matrix in Eq. (18), up to incoherent unitaries, has the form $\rho_m = \frac{1}{d+1} |d\rangle\langle d| + p|\phi_d\rangle\langle \phi_d|$, where $|\phi_d\rangle = \{(0) + (1)\}/\sqrt{2}$ is the maximally coherent state and $I_{2\times 2}$ is the identity operator, in two dimensions. $p = \sqrt{1-M_f}$.

From Theorem 2, the $l_1$ norm of coherence of the maximally coherent mixed state, given in Eq. (9), is $C(\rho_m) = (d-1)p$, and the mixedness is equal to $M(\rho_m) = \frac{1}{2p^2} \left( 1 - \text{Tr}[\rho_m^2] \right) = 1 - p^2$. Therefore, we obtain a complementarity relation between coherence and mixedness,

$$\frac{C^2(\rho_m)}{(d-1)^2} + M(\rho_m) = 1,$$  

which satisfy the equality in Eq. (3), and thus lie on the parabola, $\frac{C(\rho_m)}{(d-1)^2} + M(\rho_m) = 1$, in the coherence-mixedness plane (see Fig. 1). We call the parametrized class of states, defined by Eq. (9), that satisfy the complementarity between coherence and mixedness, i.e., any change in coherence leads to a complementary change in mixedness, as the “maximally coherent mixed states”. The MCMS class consists of pseudo-pure states, which are admixtures of the maximally coherent pure state and an incoherent state.

Similarly, one can derive a class of states with maximal mixedness for fixed coherence. Using an approach similar to Theorem 2, one can show that the set of maximally mixed coherent states also satisfy the complementarity relation and thus lie on the parabola given by Eq. (19), and hence, are of the same form as MCMS class.

Interestingly, we note that the form of MCMS remains the same if we employ a different set of measures for characterizing coherence and mixedness. For example, let us consider, the relative entropy of coherence, $C_r(\rho)$, and von Neumann entropy $S(\rho)$, as our respective measures of coherence and mixedness. It can be shown, using the formalism employed in Theorems 1 and 2, that the trade-off relation, $C_r(\rho) + S(\rho) \leq 1$, and the subsequent form of MCMS remains the same, and the apparent universality is in contrast to the measure dependent class of maximally entangled mixed states in the context of entanglement theory. However, the question of universality of the class MCMS for all equivalent sets of measures for coherence and mixedness is still open.

V. TRANSFORMATIONS WITHIN CLASSES OF STATE

The trade-off between coherence and mixedness, as established in Theorem 1, along with the complementarity relation
given by Eq. (19) for MCMS class, lead to the question of convertibility within the classes of fixed mixedness or coherence. In other words, given a class of states with fixed mixedness what are the transformations that allow one to vary the coherence, while keeping the mixedness invariant, or vice-versa. The importance of transformation and interconversion between classes of states lies in the predominant role it plays in resource theories [19, 24, 25] and its central status in the formulation of the second law(s) of thermodynamics in quantum regime [1, 3, 6–8, 11, 20]. In this section, we investigate the set of operations that allow for such transformations for qubit states.

States with fixed coherence—For a fixed value of coherence, say $\alpha$, in a fixed reference basis, say the computational basis, the states with varying mixedness, up to incoherent unitaries, are given by

$$\rho(\alpha) = \begin{pmatrix} a & \alpha \\ \alpha & 1 - a \end{pmatrix}. \quad (20)$$

Now, let us consider two states, $\rho(\alpha_1)$ and $\rho(\alpha_2)$, that have the same coherence but different mixedness. For the conditions, $(1 - \alpha_1) \geq \alpha_2 \geq \alpha_1$ or $(1 - \alpha_1) \leq \alpha_2 \leq \alpha_1$, the inequality, $\alpha_1(1 - \alpha_1) \leq \alpha_2(1 - \alpha_2)$ is satisfied. For this case, it is easy to see that $\rho(\alpha_2)$ is majorized [46–50] by $\rho(\alpha_1)$, i.e., $\rho(\alpha_2) \prec \rho(\alpha_1)$. Therefore, using Uhlmann’s theorem [47–50], we can write

$$\rho(\alpha_2) = \sum_i p_i U_i \rho(\alpha_1) U_i^\dagger, \quad (21)$$

where $U_i$’s are unitaries and $p_i \geq 0$, $\sum_i p_i = 1$. For qubit case, to keep the coherence invariant, we only allow incoherent unitaries. In the following, we shall see that the map,

$$\Phi[\rho] = p \rho + (1 - p) \sigma_x \rho \sigma_x, \quad (22)$$

where $\sigma_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ is sufficient to convert the state from $\rho(\alpha_1)$ to $\rho(\alpha_2)$, keeping the coherence unchanged. Specifically, we can achieve $\rho(\alpha_2)$ from $\rho(\alpha_1)$ using Eq. (22), by setting $p = (1 - \alpha_1 - \alpha_2)/(1 - 2\alpha_1)$, which is a valid probability for the case we are considering. Similarly, in the opposite case with the conditions $(1 - \alpha_2) \geq \alpha_1 \geq \alpha_2$ or $(1 - \alpha_2) \leq \alpha_1 \leq \alpha_2$, one can find a similar map, as in Eq. (22), from $\rho(\alpha_2)$ to $\rho(\alpha_1)$.

Therefore, given two qubit density matrices $\rho$ and $\sigma$ with the same coherence, if $\rho \ll \sigma$ ($\sigma \ll \rho$), then there will always exist a probability distribution and incoherent unitaries, leading to a transformation $\sigma \rightarrow \rho$ ($\rho \rightarrow \sigma$). An interesting observation of the above analysis arises from considering maps related to open quantum systems. For noisy operations, for example the maps in Eq. (22), the transformation between states with the same coherence is reminiscent of the phenomenon of freezing of quantum coherence [51].

States with fixed mixedness—In the same vein, we explore the transformations which convert one state to other with the same mixedness, but varying amount of coherence. The states of the form

$$\rho(a) = \begin{pmatrix} a & \sqrt{\frac{4a(1-a)-M}{4}} \\ \sqrt{\frac{4a(1-a)-M}{4}} & 1 - a \end{pmatrix}, \quad (23)$$

have the same mixedness $M$ but can have different coherences. Now, let us consider two different states $\rho(\alpha_1)$ and $\rho(\alpha_2)$. Since, these states have same mixedness, and hence same eigenvalues, they must be related to each other by a unitary similarity transformation. This similarity transformation can be easily found, once we get the eigenvectors of both the states. Let $\rho(\alpha_1)|e_i^{(1)}\rangle = \lambda_i |e_i^{(1)}\rangle$ and $\rho(\alpha_2)|e_i^{(2)}\rangle = \lambda_i |e_i^{(2)}\rangle$ ($i = 1, 2$). Now, the unitary similarity transformation $S$, such that $\rho(\alpha_2) = S \rho(\alpha_1) S^\dagger$ can be obtained from the definition $S |e_i^{(1)}\rangle = |e_i^{(2)}\rangle$. Thus, for two states of given fixed mixedness, one can always find a reversible similarity transformation between them. For an example, consider two states,

$$\rho_1 = \begin{pmatrix} 0.3 & 0.4 \\ 0.4 & 0.7 \end{pmatrix}; \quad \rho_2 = \begin{pmatrix} 0.9 & 0.2 \\ 0.2 & 0.1 \end{pmatrix}, \quad (24)$$

of the mixedness $M = 0.2$. The similarity transformation from $\rho_2$ to $\rho_1$, i.e., $\rho_2 = S \rho_1 S^\dagger$, using eigenvectors of both the states, is given by

$$S = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}, \quad (25)$$

which is a coherent unitary. In general, the state with identical mixedness but with varying coherence are connected through coherent unitaries.
VI. CONCLUSION

In our work, we show that there exists an intrinsic trade-off between the resourcefulness and the degree of noise in an arbitrary $d$-dimensional quantum system, as quantified by its coherence and mixedness, respectively. The obtained results are important from the perspective of resource theories as it allows us to quantify the maximal amount of coherence that can be harnessed from quantum states with a predetermined value of mixedness. Thus, we are able to analytically derive a class of maximally coherent mixed states, up to incoherent unitaries, that satisfy a complementarity relation between coherence and mixedness, in any quantum system.

The results presented in the work provide interesting insights on other aspects of the theory of coherence. An immediate application of our results, is in understanding the connection between the resource theories of coherence and entanglement. It was shown in a recent paper [26], that the maximum amount of entanglement that can be created between a system and an incoherent ancilla, via incoherent operations, is equal to the coherence present in the system. Using the formalism presented in [26] and the complementarity relations derived in our work, one can prove that the maximum entanglement that can be created between a quantum system and an incoherent ancilla, via incoherent operations, is bounded from above by the mixedness present in the system. Another significant aspect of the results is to address the question of order and interconvertibility between classes of quantum states, which is the fundamental premise for developing quantum resource theory and thermodynamics. Our analysis shows that, for qubit systems with a fixed coherence, majorization provides a total order on the states based on their degree of mixedness, while for fixed mixedness, all the qubit states with varying degree of coherences are interconvertible. As a future direction, it will be very interesting to investigate if there exists such a total order in $d$-dimensional states with fixed coherence based on their degree of mixedness.

To summarize, the present work deals with an important aspect of quantum physics, in particular, it addresses the question of how much a resource can be extracted from any arbitrary quantum system subjected to decoherence. We prove that there is a theoretical limit on the amount of coherence that can be extracted from mixed quantum systems and also derive the class of states that are most resourceful under decoherence. The results presented in the work provide impetus and new directions to the study of important physical quantities in open quantum systems and the effect of noise on quantum resources.
