Keywords: gold nanoparticles, surface plasmon resonance (SPR), ammonia, polyelectrolyte, layer-by-layer (LbL) deposition

In this study, we demonstrated a new approach for gas sensing using multilayer films self-assembled with cationic gold nanoparticles (AuNPs+) and anionic polyelectrolytes via layer-by-layer (LbL) deposition. The surface of AuNPs+ was modified with a cationic disulfide, [–S(CH2)2NHCO(CH2)10(CH3)3N+Br–]2. Two types of LbL film using AuNPs+ were self-assembled with anionic polyelectrolytes, poly(acrylic acid) (PAA), and poly(sodium 4-styrene sulfonate) (PSS) on quartz substrates, and their film growth was confirmed by UV–vis measurements. The 10-cycle AuNPs+/PAA film showed reproducible responses after exposure to ammonia gas (3000 ppm) and HCl treatment (0.1 M), showing absorbance changes of 0.0428 ± 0.0033 at 299 nm and 0.0053 ± 0.0013 at 544 nm for five repeated tests. On the other hand, no significant changes were observed for the 10-cycle AuNPs+/PSS film. Ammonia binding was based on the acid–base interaction between ammonia and the free carboxylic acid groups of PAA. The film's composition and morphology were also investigated by Fourier transform infrared spectroscopy (FTIR) and atomic force microscopy (AFM) measurements to clarify the sensing mechanism.

1. Introduction

In recent years, there has been considerable interest in the facile, low-cost fabrication of nanothin films for the purpose of biochemical sensing because they are advantageous for ensuring the efficient adsorption of target analytes.1 Several approaches for the deposition of organized molecular films have been examined, such as Langmuir–Blodgett (LB),2 electrostatic self-assembly (ESA),3 and layer-by-layer (LbL)4 and dip-coating5 techniques. Among them, the LbL self-assembly technique has been considered as the method with most potential for fabricating various types of nanoarchitecture.6

We have recently focused on gas sensing based on morphological changes in polyelectrolyte LbL films on optical fibres.7,8 For example, a long-period grating (LPG) optical fibre deposited

*Corresponding author: e-mail: leesw@kitakyu-u.ac.jp
with a multilayer film of poly(acrylic acid)/poly(allylamine hydrochloride) (PAA/PAH) or PAA/ poly(diallyldimethyl ammonium chloride) (PAA/PDDA) showed high sensitivity to ammonia owing to the refractive index (RI) change in the polyelectrolyte multilayer films, where the cationic polymers play two roles in assisting the PAA assembly onto the LPG and in inducing the shrinkage of the film (film density increase) owing to the binding of amine compounds to the PAA layer.

Recently, we also have demonstrated novel chemical sensors based on the LbL multilayer mesoporous film composed of silica nanospheres (SiO$_2$ NPs) with a diameter in the range of 40–50 nm on LPG fibres for the detection of organic compounds$^{(9)}$ and ammonia$^{(10)}$ and for the measurement of the RI of substances.$^{(11)}$ An additional advantage of the use of the LbL deposition technique to form the mesoporous coating, in comparison with the conventional sol-gel technique, lies in the ability to easily control the thickness of the coating layer by employing different diameters of SiO$_2$ NPs. However, the porous nature of the SiO$_2$ NP coating results in a low RI, and a functional material must be infused into the mesoporous film to increase the RI of the coating.

In this study, we report a new concept of optical gas sensing based on LbL films self-assembled with positively charged gold nanoparticles (AuNPs$^+$) and anionic polyelectrolytes. Unlike many conventional approaches based on the use of anionic gold nanoparticles,$^{(12–15)}$ the AuNPs$^+$ played a role in usual cationic polymers such as PAH and PDDA; however, their high RI and unique surface plasmon resonance (SPR) enabled us to improve the sensing ability, especially for ammonia gas, using a PAA-anchored LbL film.

2. Materials and Methods

2.1 Materials

PAA (Mw ca. 4000000), poly(sodium 4-styrene sulfonate) (PSS, Mw ca. 70000), and PDDA (Mw 200000–350000, 20 wt% in H$_2$O) were purchased from Sigma-Aldrich, USA. Ammonia (ca. 30 wt% in H$_2$O), hydrochloric acid (HCl, 1.0 M), and hydrogen tetrachloroaurate (III) tetrahydrate (99.9%) were purchased from Wako Pure Chemical Industries, Japan. Cystamine dihydrochloride and 11-bromoundecanoic acid, which were used to synthesize a cationic disulfide, and sodium tetrahydroborate were purchased from Tokyo Kasei, Japan. All of these chemicals were reagents of analytical grade and used without further purification. Deionized pure water (18.3 MΩ·cm) was obtained by reverse osmosis followed by ion exchange and filtration (Millipore, Direct-QTM).

2.2 Preparation of cationic gold nanoparticles

The synthesis of a cationic disulfide [L$_2$ (–S(CH$_2$)$_3$N(CH$_3$)$_3$+ Br$^-$)$_2$,] was carried out as described in a previous report.$^{(16)}$ L-Passivated AuNPs (AuNPs$^+$) were synthesized by a method reported by Kunitake et al., as illustrated in Fig. 1.$^{(17)}$ In brief, L (0.059 g, 0.16 mmol) was added to a 30 mL aqueous solution of hydrogen tetrachloroaurate (III) tetrahydrate (0.16 mmol), and the mixture was stirred at room temperature for 5 min. A freshly prepared aqueous solution of sodium tetrahydroborate (5.0 mL, 0.16 mol) was added dropwise into the mixture with vigorous stirring for 3 h. Then, acetone (300 mL) was added dropwise into the mixture to remove excess disulfide until the particles precipitated. The precipitate formed was filtered off using PTFE membrane with a pore size of 0.1 μm and washed with acetone to yield the AuNPs$^+$ as a black powder.
2.3 Fabrication of LbL films and ammonia gas sensing

Prior to deposition, quartz substrates were cleaned by air plasma treatment (5 min) using a plasma generator (Covance, Femto Science Co., Ltd.). The LbL method employed for AuNPs+/polyelectrolyte alternate film deposition on the quartz substrate was similarly tried as reported in our previous work. Briefly, the substrate was immersed sequentially into a solution of positively charged AuNPs+ (1.0 mg mL$^{-1}$ in water, pH ca. 9.3) and into a solution of negatively charged polymer PAA (0.05 wt% in water, pH ca. 4.3) or PSS (0.1 wt% in water, pH ca. 7.1), each for 15 min. The substrate was rinsed in distilled water and dried by flushing with nitrogen gas after each deposition step. Finally, 10-cycle films due to the LbL deposition of AuNPs+/PAA and AuNPs+/PSS were prepared. To confirm the response to ammonia, the (AuNPs+/PAA)$_{10}$ and (AuNPs+/PSS)$_{10}$ films on quartz substrates were exposed to saturated ammonia gas (ca. 3000 ppm) vaporized from a 1 wt% aqueous solution of ammonia for 15 min. After that, the films were immersed in a 0.1 M aqueous solution of HCl for 15 min to confirm their recovery to the initial state.

Transmission electron microscopy (TEM, JEOL JEM-3010, Japan) was used to investigate the average particle size of AuNPs+ under an acceleration voltage of 200 kV. In order to investigate the particle size distribution of AuNPs+, dynamic light scattering (DLS) measurements were conducted with a particle size measurement system (Otsuka Electronics, ELSZ-1000, Japan). The composition and optical responses of the films were confirmed using UV–vis spectroscopy (using a V-570 UV–vis spectrophotometer; JASCO, Japan).

For Fourier transform infrared spectroscopy (FTIR) measurements, the (AuNPs+/PAA)$_{10}$ film was prepared on a gold-coated glass plate in a manner similar to that described above, and IR spectral changes due to the exposure to the ammonia gas were measured using a Spectrum 100 FTIR spectrometer (Perkin Elmer Japan Co., Ltd.). For FTIR assessment of the disulfide compound, 1 was mixed with potassium bromide (KBr) at 1 wt%. The KBr mixture was homogenized and then pressed into a transparent KBr pellet using a press. All data were collected at a spectral resolution of 1 cm$^{-1}$.

2.4 Surface morphology study

The surface morphology of the prepared films was studied with a JEOL JSPM-5200 atomic force microscope (AFM) working in noncontact mode using a MicroMash NSC12/Ti-Pt/15 silicon cantilever (curvature tip radius <40 nm, tip length 15–20 μm).
3. Results and Discussion

3.1 LbL self-assembly of AuNPs+ with polyelectrolytes

The prepared AuNPs+ were stable in water and showed a clear SPR band at 520 nm, as shown in Fig. 2(a). From the results of DLS measurement [inset of Fig. 2(a)] and TEM observation [Fig. 2(b)], the average particle size was estimated to be ca. 5 nm in diameter, which is in good agreement with Refs. 16 and 17. Thus, the whole size of 1-passivated AuNPs+ is estimated to be ca. 10 nm, while the size of the gold core is 5 nm.\(^{(16,17)}\)

UV–vis spectral changes due to the film deposition of AuNPs+ with an alternate layer of PAA or PSS on quartz substrates are shown in Figs. 3(a) and 3(b), respectively, when the outermost layer was covered with AuNPs+. As the number of layers increases, the absorbance increases in the spectral region of 200–500 nm. In addition, both films showed a pronounced band in the UV–vis spectra at around 544 nm in the visible region. This absorption band linearly increased with the
increase in the number of bilayers, indicating a uniform film growth on the quartz substrate. Both insets of Fig. 3 show absorbance increases measured at 229 and 544 nm during the film deposition.

The absorption band at 544 nm originates from the gold nanoparticles, AuNPs⁺, showing a redshift of 24 nm from the original SPR band (at 520 nm) of AuNPs⁺ in water. This phenomenon can be plausibly explained by the fact that the electronic (dielectric) environment of AuNPs⁺ was considerably changed when the gold nanoparticles were covered with a PAA or PSS layer by electrostatic interaction. Consequently, the distance between the gold nanoparticles became small, leading to a redshift of the SPR absorption maximum in water. Interestingly, both the AuNPs⁺/PAA and AuNPs⁺/PSS films showed almost the same absorbance at 544 nm after 10 deposition cycles had been completed. This suggests that PAA may be assembled with AuNPs⁺ via electrostatic interaction, similarly to that of PSS with AuNPs⁺, as given in Eqs. (1) and (2). Plausibly, this may be attributed to the fact that the quaternary ammonium salt, RN⁺(CH₃)₃Br⁻, is stable and almost unaffected by the pH of the solution.

\[
\begin{align*}
RN⁺(CH₃)₃Br⁻ + R'SO₃⁻Na⁺ &\rightleftharpoons RN⁺(CH₃)₃O₃SR' + Na⁺Br⁻ \quad (1) \\
RN⁺(CH₃)₃Br⁻ + R'CO₂H &\rightleftharpoons RN⁺(CH₃)₃O₂CR' + H⁺Br⁻ \quad (2)
\end{align*}
\]

### 3.2 Ammonia gas sensing

In the case of the AuNPs⁺/PAA film, UV–vis spectra, which were measured after the film was exposed to the ammonia gas vaporized from a solution of 1 wt% ammonia for 30 min and immersed in a solution of HCl in water (0.1 M) for 15 min, were reproducible, as shown in Fig. 4(a), and the absorbance changes at 299 and 544 nm were 0.043 ± 0.0033 and 0.0053 ± 0.0013 for five repeated tests [Fig. 4(b)], respectively. This optical change in the AuNPs⁺/PAA film seems to be attributable to the deprotonation or protonation of PAA, which usually induces a morphological change in the LbL multilayer films. The swelling and shrinking of the PAA polymer layers in the film might affect the SPR absorption of AuNPs⁺. However, no wavelength shift was observed in the SPR absorption maximum at 544 nm. Probably this results from the close packing of AuNPs⁺ in the film, as predicted through the large wavelength shift of the SPR band from 520 to 544 nm of AuNPs⁺.

Figure 4(c) shows UV–vis spectra of the 10-cycle AuNPs⁺/PSS film after the film was exposed to the ammonia gas for 30 min and immersed into an aqueous solution of HCl for 15 min. No significant changes were observed from the repeated tests, as shown in Fig. 4(d). This result is attributed to the absence of response of PSS to ammonia and HCl.

### 3.3 FTIR measurements

To investigate the film composition and the binding mechanism of ammonia, FTIR measurements were carried out. Figure 5 shows FTIR spectra of the cationic disulfide, 1, and a 10-cycle AuNPs⁺/PAA film before and after exposure to the ammonia gas and after HCl treatment. In curve (a) of Fig. 5, three unique peaks at 3296, 1639, and 1547 cm⁻¹ correspond to the N–H stretch and two types of C–O stretch of the amide group (–CONH–). In addition, the peaks at 2917 and 2850 cm⁻¹ are assigned to the C–H stretch of the –CH₂– and –N–CH₃ groups of 1, respectively. On the other hand, the peak due to the C–O stretch of the free –COOH groups of PAA was observed
at 1720 cm$^{-1}$ along with the characteristic peaks of 1 in curve (b) of Fig. 5. The asymmetric and symmetric C–O stretches of the PAA carboxylate group (–COO–) were also observed at 1544 (strong) and 1414 cm$^{-1}$ (very weak), respectively. A small broad peak at around 1453 cm$^{-1}$ may be attributed to the C–H bending vibration of the –CH$_2$– group of 1 and PAA. These results indicate that PAA
was successfully employed in the LbL film and the free carboxylic acid groups of PAA remained, which can be used as selective binding sites for ammonia.

The IR spectrum of the AuNPs\(^+\)/PAA film exposed to the ammonia gas is shown in curve (c) of Fig. 5. The intensity of the peak of the C–O stretching vibration (–COOH) at 1720 cm\(^{-1}\) decreased after exposure of the film to the ammonia gas. In general, the –COOH functional moiety undergoes transformation to the –COO\(^-\) group by the acid–base reaction. However, there were no clear changes in the intensities of the peaks due to symmetric and asymmetric stretching vibrations of the –COO\(^-\) group at 1414 and 1544 cm\(^{-1}\), respectively, as a consequence of the exposure of the film to the ammonia gas. Probably this result is attributable to the fact that the weak asymmetric C–O stretch of the –COO\(^-\) group at 1544 cm\(^{-1}\) overlapped with the relatively strong C–O stretch of the amide group (–CONH–) at 1547 cm\(^{-1}\). In addition, the C–O stretch of the amide group at 1570 cm\(^{-1}\) become stronger via hydrogen bonding between the self-assembled alkyl thiolates on the AuNPs\(^+\). In contrast, it is observed that the other peaks of the amide group at 3296 and 1639 cm\(^{-1}\) were attenuated by the hydrogen bonding. Interestingly, the intensities of the peaks associated with PAA were recovered when the film was treated with HCl, showing a decrease in transmittance at 1414 cm\(^{-1}\) and an increase in transmittance at 1720 cm\(^{-1}\), as shown in curve (d) of Fig. 5.

3.4 **Morphological study of sensing mechanism**

To clarify the UV–vis and FTIR spectral changes induced by ammonia gas adsorption and HCl treatment, morphological changes of the AuNPs\(^+\)/PAA film were investigated. Figure 6 shows AFM images of the surface morphologies of the 10-cycle AuNPs\(^+\)/PAA film recorded before and after exposure to the ammonia gas and after HCl treatment. The roughness of the AuNPs\(^+\)/PAA film was markedly changed from 57 nm [Figs. 6(a) and 6(b)] to 23 nm [Figs. 6(c) and 6(d)] after exposure to the ammonia gas and the surface became smoother. This significant morphological change may be attributed to the aggregation of the PAA polymer layers due to the improved electrostatic

![Fig. 6. (Color online) AFM images of the 10-cycle AuNPs\(^+\)/PAA film (a, b) before and (c, d) after exposure to ammonia gas and (e, f) after HCl treatment.](image)
interaction with the AuNPs\(^+\). Interestingly, the original surface morphology could be recovered by HCl treatment [Figs. 6(e) and 6(f)]. This reveals that HCl treatment can be used to restore the film properties for ammonia sensing, as it was confirmed by the FTIR measurements.

In contrast, the 10-cycle AuNPs\(^+\)/PSS film showed a much more uniform and smooth surface compared with that of the AuNPs\(^+\)/PAA film, and there were no significant changes in the surface morphologies observed before [Figs. 7(a) and 7(b)] and after [Figs. 7(c) and 7(d)] exposure to the ammonia gas and after HCl treatment [Figs. 7(e) and 7(f)]. The roughness of the AuNPs\(^+\)/PSS film was estimated to be ca. 10 nm in every case. These results are in good agreement with the UV–vis spectral changes in the AuNPs\(^+\)/PSS film, indicating no response of PSS to ammonia.

![Schematic](image)

**Fig. 8.** (Color online) Schematic illustration of the correlation between the optical and morphological changes in the AuNPs\(^+\)/PAA film due to exposure to ammonia gas and HCl treatment.
The decrease in the thickness of the AuNPs+/PAA film proves our hypothesis concerning the increase in film density, as illustrated in Fig. 8. The sensing mechanism for the binding to ammonia can be considered to be based on the acid–base interaction between ammonia and the carboxylic acid moiety of PAA. As a result, the –COOH functional moiety undergoes transformation to –COO⁻ and electrostatic interactions between the PAA and AuNPs⁺ layers can be enhanced. Similar sensing performances to those recorded when PAA was coupled with PDDA or PAH are observed.⁷,⁸ On the basis of the FTIR and AFM results, we can conclude that the shrinkage of the AuNPs⁺/PAA film can be induced by the adsorption of ammonia, and this leads to a large optical change in the near-UV region, which mainly depends on the absorption of the AuNPs⁺.

4. Conclusions

In this study, we demonstrated optical gas sensing based on cationic gold nanoparticles (AuNPs⁺) LbL multilayer films self-assembled with anionic polyelectrolytes such as PAA and PSS. The AuNPs⁺/PAA film was optically sensitive to ammonia and its response was reproducible by the HCl treatment of the film, whereas no response was observed for the AuNPs⁺/PSS film. In addition, the response of the AuNPs⁺/PAA film to ammonia could be morphologically confirmed by AFM measurements. Unfortunately, the optical response based on the SPR absorption of AuNPs⁺ was not remarkable, which may be attributed to the close packing of AuNPs⁺ in the film. The coverage of AuNPs⁺ in individual layers should be more precisely controlled to solve such a problem. Anyway, our current approach provides several possibilities for gas sensing, such as improvements in gas diffusion and electrochemical properties owing to nanoparticles, and selectivity to hydrophobic compounds owing to long alkyl thiolates self-assembled on gold nanoparticles, which will be a challenge in the near future.
