ABSTRACT: We compute by supersymmetric localization the expectation values of half-BPS ’t Hooft line operators in $\mathcal{N} = 2$ $U(N)$, $SO(N)$ and $USp(N)$ gauge theories on $S^1 \times \mathbb{R}^3$ with an $\Omega$-deformation. We evaluate the non-perturbative contributions due to monopole screening by calculating the supersymmetric indices of the corresponding supersymmetric quantum mechanics, which we obtain by realizing the gauge theories and the ’t Hooft operators using branes and orientifolds in type II string theories.

1 Introduction

The ’t Hooft line operator, defined by a singular Dirac monopole boundary condition
\[ \frac{1}{2} F_{\mu \nu} dx^\mu \wedge dx^\nu \sim \frac{B}{2} \text{vol}_{S^2} \]  
(B: magnetic charge) \hspace{1cm} (1.1)
on a gauge field, is an interesting disorder operator that universally exists in all four-dimensional (4d) gauge theories. The ’t Hooft operator has played important roles in understanding the physics of gauge theories both in non-supersymmetric [1] and supersymmetric (SUSY) [2–8] settings.

In [9] the supersymmetric localization method was developed for the computation of the expectation values of half-BPS ’t Hooft operators in 4d \( \mathcal{N} = 2 \) gauge theories on \( S^1 \times \mathbb{R}^3 \). Recently, Brennan, Dey, and Moore modernized the localization technique for ’t Hooft operators, in the case of the SU(\( N \)) gauge group, and proposed to use the supersymmetric quantum mechanics (SQMs) that compute the non-perturbative monopole screening (often also called monopole bubbling) contributions [10–12]. In our previous paper [13] that considered the U(\( N \)) gauge theory with hypermultiplets in the fundamental representation (SQCD), we explored, by extending a result in [14], the relation between wall-crossing in the SQMs and the ordering of ’t Hooft operators along the line (in \( \mathbb{R}^3 \)) on which the operators are inserted.

The main aim of this paper is to generalize the results of these works in two directions. First, for the U(\( N \)) gauge group, we compute the correlation functions involving ’t Hooft operators with non-minimal charges and study the relation between wall-crossing and the ordering of such operators, whereas [13] treated only the cases with minimal charges. Second, we consider gauge groups other than SU(\( N \)) or U(\( N \)) and perform localization calculations for SO(\( N \)) and USp(\( N \)) gauge groups.

Let us elaborate on the summary in the previous paragraph. We consider the ’t Hooft operator \( T_B \) with a magnetic charge \( B \) (an element of the cocharacter lattice \( \Lambda_{\text{cochar}} \)) of a gauge group \( G \). In general the operator \( T_B \) is a linear combination of products of more
fundamental operators, and we need to supply more information than the charge $B$ to fully specify the operator as we will do on a case-by-case basis. The vacuum expectation value \( \langle T_B \rangle \) on $S^1 \times \mathbb{R}^3$ with an $\Omega$-deformation along the $(x^1, x^2)$-plane is a function of a pair of parameters $(a, b)$ taking values in the complexified Cartan subalgebra, and takes the form

$$\langle T_B \rangle = \sum_{v \in \mathfrak{B} + \Lambda_{\text{coroot}}} e^{v \cdot b} Z_{1\text{-loop}}(v) Z_{\text{mono}}(B, v),$$

(1.2)

where $\Lambda_{\text{coroot}}$ is the coroot lattice and $| \bullet |$ denotes the norm given by the Killing form $[9]$. The vev also depends on the $\Omega$-deformation parameter, and the complexified masses, which we suppressed in (1.2). The one-loop contributions $Z_{1\text{-loop}}(v)$ were determined for general gauge groups and matter contents in [9]. In [8, 9] non-perturbative contributions $Z_{\text{mono}}$ due to monopole screening were evaluated for gauge group $U(N)$ based on the correspondence [15] between monopoles with Dirac singularities and instantons on the Taub-NUT space. The new method of [10–12] identifies the monopole screening contributions with the supersymmetric indices of the appropriate SQMs and evaluates them by localization [16–18] using the Jeffrey-Kirwan (JK) residue prescription [19], possibly combined with extra approximate calculations to capture Coulomb branch contributions. The SQMs can be found by realizing the ’t Hooft operators using branes in string theory.

In this paper we extend the analysis of [13] to non-minimal ’t Hooft operators in the $U(N)$ gauge theory with $2N$ flavors, and to ’t Hooft operators in the $SO(N)$ gauge theory with $N - 2$ flavors and the $USp(N)$ gauge theory with $N + 2$ flavors. A flavor is a hypermultiplet in the fundamental (also called vector for $SO(N)$) representation of the gauge group. The gauge theories whose matter hypermultiplets are in this representation will be referred to as SQCDs. We extend the relation between wall-crossing and operator ordering to the cases with non-minimal higher charges. We also study ’t Hooft operator correlators in the theories with an adjoint hypermultiplet ($N = 2^*$ theories) with gauge groups $U(N)$, $SO(N)$, and $USp(N)$.

To read off the SQMs we will realize the gauge theories, ’t Hooft operators, and monopole screening in D2-D4-NS5-D6-brane systems, together with an orientifold 4- or 6-plane for the $SO(N)$ or $USp(N)$ gauge group. For gauge group $U(N)$ our brane systems are T-dual to the D1-D3-NS5-D7-brane systems considered in [10–12], and the 4d theory is realized on D4-branes as in [20]. Gauge groups can be modified from $U(N)$ to $SO(N)$ or $USp(N)$ by introducing an orientifold 4- or 6-plane to the brane systems [21–24]. We will propose that the ’t Hooft operators engineered by our brane constructions have the magnetic charges that correspond to exterior powers $\wedge^k V$ of the fundamental (or vector) representation $V$ of the Langlands dual of the gauge group. (For the unitary gauge group we will also realize the operators that correspond to $\wedge^k \bar{V}$.)

Throughout the paper, we do not distinguish different global structures (gauge group topologies and discrete theta angles [25]) associated with a given gauge algebra. Our

---

1A summary of the prescription can be found in appendix A.2 of our previous paper [13].

2Each number of flavors is such that the beta function for the (non-abelian) gauge coupling vanishes.
brane construction realizes\(^3\) minimal ’t Hooft operators, and the global structure of the corresponding gauge theory must be one of those which admit the minimal operators.

The organization of the paper is as follows. In section 2, we propose a brane construction of ’t Hooft operators in the U(N), SO(N) and USp(N) gauge theories. Section 3 studies non-minimal ’t Hooft operators in the U(N) gauge theories.\(^4\) In sections 4 and 5 we study ’t Hooft operators in the SO(N) and USp(N) gauge theories, respectively. We summarize our results and discuss open problems in section 6. Appendix A collects useful facts about the U(N), SO(N) and USp(N) groups. Appendix B contains formulas for the one-loop determinants in 4d and 1d gauge theories. In appendix C we study the correlation functions that involve an operator with magnetic charge corresponding to \(\wedge^2V\) in SO(N) and USp(N) SQCDs. We discuss the subtleties exhibited by these correlators and discuss their possible interpretations.

2 Brane construction of ’t Hooft operators

In this section we propose a brane construction of ’t Hooft line operators in 4d \(\mathcal{N} = 2\) theories with a gauge group U(N), SO(N), or USp(N). We will focus on 4d theories with a single gauge group. The constructions of the 4d theories themselves have been well-known \[20–22, 24\]. Our aim is to engineer ’t Hooft operators in a useful way by combining the results of these earlier works with the insights from the works of Brennan, Dey and Moore \[10–12\]. In particular we explain how to read off the SQMs that capture the monopole screening contributions to the ’t Hooft operator correlation functions. We also propose what we call the “extra term prescription”, motivated by earlier works on instanton counting. This prescription will be used in the computations for SO and USp gauge theories in later sections. Finally, we will generalize some conjectures we made in \[13\] regarding the SQMs, wall-crossing, and the operator ordering.

2.1 U(N) SQCD and \(\mathcal{N} = 2^*\) theory on D4-branes

Let us begin with the brane construction of ’t Hooft operators in the 4d \(\mathcal{N} = 2\) U(N) SQCD with \(N_F\) flavors. We consider type IIA string theory in flat space \(\mathbb{R}^{1,9}\) with coordinates \(x^\mu (\mu = 0, \ldots, 9)\) and introduce two NS5-branes placed at two points in the \((x^6, \ldots, x^9)\)-space separated only in the \(x^6\)-direction by a finite distance. We introduce \(N\) D4-branes that extend in the \((x^0, \ldots, x^3, x^6)\)-directions and are suspended between the two NS5-branes. Since the D4-brane is put on a finite segment in the \(x^6\)-direction, we obtain a 4d effective field theory at low energies living in the \((x^0, \ldots, x^3)\)-spacetime. To introduce hypermultiplets in the fundamental representation we include \(N_F\) D6-branes between the two NS5-branes. The D6-branes are point-like in the \((x^4, x^5, x^6)\)-space. This is the same

---

\(^3\)There can be subtleties in the brane realization of ’t Hooft operators. For example, in \[10, 13, 14\], it has been found that some SQMs for ’t Hooft operators in the 4d \(\mathcal{N} = 2\) SU(N) (or U(N)) gauge theory with an odd number of flavors require a Chern-Simons term to avoid an anomaly. However the necessity of the Chern-Simons term is not clear from the brane construction.

\(^4\)Within each subsection one symbol denotes a single quantity, but in different subsections it may denote different quantities. For example the symbol \(Z_{ij}\) denotes the same quantity \(\ref{3.2}\) in sections 3.1.1 and 3.1.2 (both within a single subsection 3.1), but it denotes different quantities in the other subsections.
Figure 1. (a): the brane configuration for the 4d $\mathcal{N}=2$ SQCD. The $(x^4, x^6)$-directions are shown explicitly. (b): the 4d $\mathcal{N}=2$ quiver diagram corresponding to (a). A circle with $N$ means the U($N$) vector multiplets and a solid line represents a hypermultiplet in the fundamental representation. The number in a box implies the number of the fundamental hypermultiplets. We will use similar notation for 2d quivers later. (c): the brane configuration for the SQCD with $N_F=2$, with a D2-brane and an NS5'-brane realizing an ’t Hooft operator. In addition to the $(x^4, x^6)$-directions of (a), another direction that collectively represents $(x^1, x^2, x^3)$ is added to the figure. While the D2-brane ends on the NS5-branes, the NS5'-brane (despite the $\otimes$ symbol in the figure) extends infinitely along the $x^6$-direction and intersects the NS5-branes. (d): the projection of the same brane system to the $x^4$-direction and another direction that collectively represents $(x^1, x^2, x^3)$. The NS5'-brane and the D2-brane inserts an ’t Hooft operator with charge $B = e_N$.

construction as in [20], but we take the gauge group to be U($N$) rather than SU($N$);\(^5\) as we will see the U($N$) gauge group is more natural when considering ’t Hooft operators. The brane configuration realizing the 4d U($N$) gauge theory with $N_F$ flavors is depicted in figure 1a, where the $(x^4, x^6)$-space is shown explicitly.

Magnetic charges can be introduced as the end points of D2-branes on the D4-branes [26]; the D2-branes are also bounded by the two NS5-branes. To make the magnetic monopoles infinitely heavy, i.e., to construct ’t Hooft operators rather than dynamical ’t Hooft-Polyakov monopoles, we let the D2-branes terminate at another NS5-brane at the opposite ends; we call it an NS5'-brane.\(^6\) The brane configuration for an example of an ’t Hooft operator in the 4d $\mathcal{N}=2$ U($N$) SQCD is depicted in figures 1c and 1d. The magnetic charge of the ’t Hooft operator may be read off from which D4-brane the D2-brane ends on. We also summarize the directions in which these branes are extended in table 1.

We can also construct the 4d U($N$) $\mathcal{N}=2^*$ theory and its ’t Hooft operators in a similar manner. For this we compactify the $x^6$-direction on a circle and identify the two NS5-branes [20]. If we take the quotient by the simple shift $x^6 \rightarrow x^6 + 2\pi L$ with the other coordinates fixed, then the hypermultiplet in the adjoint representation in the 4d

---

\(^5\)One may first realize the SU($N+1$) theory by the NS5-D4-D6 system [20] and then reduce to the U($N$) $\subset$ SU($N+1$) theory by giving an appropriate expectation value to the adjoint scalar.

\(^6\)For the purpose of realizing an ’t Hooft operator, we can also make the D2-branes semi-infinite in the $x^6$-direction. As shown in [10] in a similar set-up, terminating the D2-branes by an NS5'-brane allows us to read off the SQMs that compute screening contributions.
Table 1. The directions (×) in which branes extend for a configuration engineering \('t\) Hooft operators in the 4d \(U(N)\) gauge theories. For the 4d \(\mathcal{N} = 2^*\) \(U(N)\) gauge theory, the \(x^6\)-direction is circle-compactified with a twist as in (2.1) and no D6-branes are introduced. We also list the directions of the orientifolds which we will discuss in sections 2.2 and 2.3 to realize gauge groups different from \(U(N)\).

\[
\begin{array}{cccccccc}
0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 \\
\hline
\text{D4/O4} & \times & \times & \times & \times & \times & \times & \times & \times & \times \\
\text{D6/O6} & \times & \times & \times & \times & \times & \times & \times & \times & \times \\
\text{NS5} & \times & \times & \times & \times & \times & \times & \times & \times & \times \\
\text{D2} & \times & \times & \times & \times & \times & \times & \times & \times & \times \\
\text{NS5'} & \times & \times & \times & \times & \times & \times & \times & \times & \times \\
\end{array}
\]

\(\mathcal{N} = 2^*\) \(U(N)\) gauge theory is massless. To introduce the (complex) mass \(m\) for the adjoint hypermultiplet we include a shift in the \((x^4, x^5)\)-directions when we go round the circle. Namely, we identify

\[
(x^4, x^5, x^6, x^{\text{other}}) \sim (x^4 + \text{Re} \, m, x^5 + \text{Im} \, m, x^6 + 2\pi L, x^{\text{other}}). \quad (2.1)
\]

We let \(N\) D4-branes end on the single NS5-brane from the both sides. The massless modes of the D4-D4 open strings that do not cross the NS5-brane form the \(\mathcal{N} = 2\) \(U(N)\) vector multiplet. The lightest modes of the D4-D4 open strings that cross the NS5-brane form the adjoint hypermultiplet whose mass \(m\) is given by the shift.\(^7\)

In our previous paper [13] we focused on minimal \('t\) Hooft operators, corresponding to the fundamental or anti-fundamental representation of the Langlands dual of the gauge group \(G = U(N)\). The minimal \('t\) Hooft operator is realized by a single D2-brane ending on an NS5'-brane. In this paper we consider non-minimal \('t\) Hooft operators for the \(U(N)\) gauge group. We propose that

\[ k \text{ D2-branes stretched between a single NS5'}-brane and the stack of D4-branes realize an 't Hooft operator whose magnetic charge corresponds to the rank-} k \text{ anti-symmetric representation of the Langlands dual group }G^\vee = U(N). \]

More precisely, for an NS5'-brane placed on the right (left) of the D4-branes, we propose that the \(k\) D2-branes correspond to the \(k\)-th exterior power \(\wedge^k V\) (\(\wedge^k \overline{V}\)) of the fundamental (anti-fundamental) representation of \(G^\vee\).\(^8\) The brane configuration for \(\wedge^k V\) is depicted in figure 2. To realize BPS \('t\) Hooft operators, the s-rule [27] requires that for each pair of an NS5'-brane and a D4-brane there is at most a single D2-brane between them.

\(^7\)Starting with this brane construction of the \(\mathcal{N} = 2^*\) theory, one can obtain the pure super Yang-Mills theory by taking the limit \(m \to \infty\) and by integrating out the adjoint matter. This procedure is related to a similar procedure in [12] by the T-duality in the \(x^6\)-direction. The single NS5-brane localized in the \((x^6, x^7, x^8, x^9)\)-space turns into a 4d geometry with the topology of \(\mathbb{R}^4\) in the \((x^4_\text{dual}, x^5_\text{dual}, x^8, x^9)\)-directions, with background supergravity fields determined by \(m\) in (2.1). (If \(m\) were zero this geometry would be the single-center Taub-NUT space.) The T-duality turns D4 into D3, and D2 into D1.

\(^8\)We mentioned this possible correspondence in footnote 13 of [13]. See also [11] for a related discussion.
Since the D2-branes end on k D4-branes, the corresponding ’t Hooft operator is charged under the Cartan generators of the Langlands dual group associated to the k D4-branes. Hence it is natural to expect that the configuration in figure 2 realizes an ’t Hooft operator that corresponds to the rank-k anti-symmetric representation of U(N). For the N = 2* U(N) theory, our proposal above is S-dual to the fact [28], well known in the context of AdS/CFT, that a single D5-brane with k units of the fundamental string charge realizes a Wilson line operator for the U(N) gauge theory realized on a stack of N D3-branes. In section 3 we will provide quantitative evidence for our proposal by generalizing our analysis for minimal operators in [13].

2.2 SO/USp SQCD on D4-branes and an O4-plane

We can change the gauge group by introducing an orientifold. The inclusion of an O4-plane along the directions of the D4-branes in the brane configuration for the 4d \( \mathcal{N} = 2 \) U(N) SQCD described in section 2.1 engineers an SQCD with a gauge group SO or USp [21, 22].

Both the O4-plane and the D4-branes extend in the \((x_0, x_1, x_2, x_3, x_6)\)-directions. When the O4-plane is placed at \( x_4 = x_5 = x_6 = x_7 = x_8 = x_9 = 0 \), then the orientifold action on the spacetime coordinates is

\[
(x^{0,1,2,3}, x^{4,5,6,7,8,9}) \mapsto (x^{0,1,2,3}, -x^{4,5,6,7,8,9}).
\]  

(2.2)

The brane configuration needs to be compatible with the orientifold action.

Let us look at the brane construction in more detail. We consider \( N \) D4-branes, including physical as well as mirror image branes, stretched between two NS5-branes. Different types of the orientifold yield different gauge groups. A stack of \( n \) physical D4-branes on top of the O4-\(-\)plane \((N = 2n)\) gives rises to the SO(2n) gauge group. On the other hand a stack of \( n \) physical D4-branes on top of an O4-\(-\)plane realizes the SO(2n + 1) gauge group. Because the D4-brane charge of an O4-\(-\)plane is the same as that of an O4-\(-\)plane with a half D4-brane,\(^{10}\) the configuration effectively contains \( N = 2n + 1 \) D4-branes.

\(^9\)More generally one can realize a linear quiver theory with alternating so and usp gauge algebras by including more than two NS5-branes. When an O4-plane crosses an NS5-brane its NS \( Z_2 \) charge changes, while when an O4-plane crosses a D6-brane its RR \( Z_2 \) charge changes [29].

\(^{10}\)An O4-\(-\)plane may be referred to as an O4\(-\)plane [30] since the total D4-brane charge is zero.
Figure 3. (a): a brane construction of the SO/USp SQCD with an O4-plane. The \((x^4, x^6)\)-directions are shown explicitly, and the mirror image is omitted. (b): the brane configuration for the SQCD with \(n = N_F = 2\). In addition to the \((x^4, x^6)\)-directions of figure 3a, another direction that collectively represents \((x^1, x^2, x^3)\) is added to the figure. A D2-brane with an NS5'-brane realizing the minimal 't Hooft operator is also shown.

including the mirror images. Finally a stack of \(n\) physical D4-branes on top of an O4+-plane yields the gauge group USp(2\(n\)). For the O4+-plane a half D4-brane is not allowed to be stuck there, and \(N = 2n\) is the only possibility. Adding \(N_F\) D6-branes between NS5-branes introduces \(N_F\) hypermultiplets in the fundamental (vector) representation. The gauge symmetry on D6-branes depends on the type of the O4-plane. We summarize the gauge symmetries on D4- and D6-branes in the following table.

|        | O4−  | ˜O4− | O4+  |
|--------|------|------|------|
| D4     | SO(2\(n\)) | SO(2\(n\) + 1) | USp(2\(n\)) |
| D6     | USp(2\(N_F\)) | USp(2\(N_F\)) | SO(2\(N_F\)) |

This is consistent with the flavor symmetry group for SO and USp gauge theories. Namely the flavor symmetry of an SO gauge theory is the USp-type and that of an USp gauge theory is the SO(even)-type. The brane configuration for the SO/USp SQCD is depicted in figure 3a.

As with the construction of the minimal 't Hooft operator in the 4d \(\mathcal{N} = 2\) U(\(N\)) SQCD, a minimal 't Hooft line operator, corresponding to the fundamental representation \(V\) of the Langlands dual of the gauge group, should be realized by a D2-brane stretched between a D4-brane and an NS5'-brane, as indicated in figures 3b and 4a. More generally we propose that for \(k \leq n\),

\(k\) D2-branes, stretched between the stack of \(n\) D4-branes and a single NS5'-brane, realizes an 't Hooft operator whose magnetic charge \(B \in \Lambda_{\text{cochar}}\) corresponds to \(\wedge^k V\), the rank-\(k\) anti-symmetric representation of the Langlands dual \(G'\) of the gauge group \(G\).

As an example, the brane configuration for \(\wedge^2 V\) is shown in figure 4b.

\(^{11}\)We do not consider an ˜O4+-plane, which also leads to the USp(\(N\)) gauge group.
2.3 SO/USp SQCD and $\mathcal{N} = 2^*$ theory on D4-branes and an O6-plane

In section 2.2, we realized an SO or USp gauge group using an O4-plane. We can also use an O6-plane to engineer SO($N$) or USp($N$) gauge theories [23]. An O6-plane is extended in the same directions as those of D6-branes, namely in the $(x^0, x^1, x^2, x^3, x^7, x^8, x^9)$-directions. When an O6-plane is placed at $x^4 = x^5 = x^6 = 0$ the orientifold action on the spacetime coordinates is

$$ (x^{0,1,2,3,4,5,6,7,8,9}) \mapsto (x^{0,1,2,3,4,5,6,7,8,9}). $$

The brane configuration needs to be compatible with the orientifold action.

As in the case with an O4-plane, different types of an O6-plane give different gauge groups. When the O6-plane is the O6$^+$-plane the SO($N$) gauge group is realized. $N$ is the number of D4-branes including the mirror images. When $N$ is even ($N = 2n$), the gauge group is SO($2N$). It is also possible to consider $N$ is odd ($N = 2n+1$) where a half D4-brane is stuck at the O6$^+$-plane in addition to $n$ physical D4-branes. Such a configuration gives rise to the SO($2n+1$) gauge group. When the O6-plane is the O6$^-$-plane we cannot have a D4-brane stuck at the orientifold. Then the number of the D4-branes including the mirror image is always even and $n$ physical D4-branes with the O6$^-$-plane yield the USp($2n$) gauge...
(a): a brane construction of the SO/USp $\mathcal{N} = 2^*$ theory with an O6-plane. The (half) D4-brane on top of the O6-plane is present only when the gauge group is SO($2n + 1$). (b): a realization of the 't Hooft operator corresponding to the fundamental representation $V$ and $B = e_n$.

The brane configuration with the O6-plane is depicted in figure 5a.

O6-planes can also be used to construct the $\mathcal{N} = 2^*$ SO or USp gauge theory [24]. We compactify the $x^6$-direction on a circle with a shift as in (2.1). We introduce two O6-planes, one at $(x^4, x^5, x^6) = (0, 0, 0)$ and the other at $(x^4, x^5, x^6) = \left( \frac{1}{2} \text{Re} m, \frac{1}{2} \text{Im} m, \pi L \right)$. The first O6-plane identifies spacetime points related by (2.3). The identification due to the second O6-plane automatically follows from (2.1) and (2.3). As in the U($N$) case we introduce a single NS5-brane at $x^6 = \pi L$ and let $N$ D4-branes, including the mirror images, end on it. The type of the O6-plane at $(x^4, x^5, x^6) = (0, 0, 0)$ determines the gauge group according to the table above. The O6$^+$-plane yields the SO($N$) gauge group, and the O6$^-$-plane gives rise to the USp($N$) gauge group with $N$ even. The type of the other O6-plane determines the representation of the hypermultiplet arising from the fundamental strings that cross the NS5-brane and end on the D4-branes. An O6$^+$-plane gives the rank-2 anti-symmetric representation, while an O6$^-$/plane gives the rank-2 symmetric representation. Since the net RR charge of the O6-planes localized on a compact space has to vanish, we get an anti-symmetric representation for SO($N$) and a symmetric representation for USp($N$), corresponding to the $\mathcal{N} = 2^*$ theory. We depict the brane configuration in figure 6.

As in the U($N$) and the O4-plane cases, D2-branes ending on the stack of D4-branes and an NS5$'$-brane should realize 't Hooft operators in the SO/USp SQCD or $\mathcal{N} = 2^*$ theory constructed with O6-planes. We propose that for $k \leq N/2$, $k$ D2-branes stretched between the stack of D4-branes and a single NS5$'$-brane realize an 't Hooft operator whose
magnetic charge $B \in \Lambda_{\text{cochar}}$ corresponds to $\wedge^k V$, the rank-$k$ anti-symmetric representation. Examples of such 't Hooft operators are shown in figures 6b and 7. In sections 4.2 and 5.2 we will make use of these brane configurations with O6-planes to obtain the SQMs that describe monopole screening in the expectation values of 't Hooft operators in the $\mathcal{N} = 2^*$ SO/USp gauge theories. We will provide quantitative evidence for our proposal by comparing the supersymmetric indices of SQMs with the Moyal products (to be defined in section 2.6) of the two minimal 't Hooft operators.

2.4 SQMs on 't Hooft operators

So far we have constructed 't Hooft operators in the 4d $\mathcal{N} = 2$ U/SO/USp SQCD or $\mathcal{N} = 2^*$ U/SO/USp gauge theories using branes and orientifolds in type IIA string theory. A physical quantity associated with the 't Hooft operators is the expectation value of their product. The expectation value may or may not contain non-perturbative contributions, namely monopole screening contributions. The brane construction is useful to understand the monopole screening contributions of the 't Hooft operators [10–12].

Let us look at an example of the 4d $\mathcal{N} = 2$ U(2) SQCD with 4 flavors. The brane configuration where we insert two minimal 't Hooft operators with the total magnetic charge $B = -e_1 + e_2$ is depicted in figure 8a. The charge may be screened by a smooth monopole, with the opposite charge, corresponding to a D2-brane stretched between the two D4-branes as in figure 8b. By tuning the positions we can align and combine the three D2-branes as in figure 8c to obtain a single D2-brane between the two NS5'-branes. This configuration corresponds to the monopole screening sector with $v = 0$. Since the D2-brane is also bounded by NS5-branes and NS5'-branes, the theory that lives on the D2-brane realizes a 1d theory, i.e., an SQM, at low energies.

The SQM is the dimensional reduction of a 2d $\mathcal{N} = (0, 4)$ supersymmetric gauge theory [11, 16, 31, 32]. The matter content of the SQM can be read off from fundamental strings connecting D-branes in the configuration. The matter content is summarized as follows.

**Figure 7.** (a): a realization of the 't Hooft operator corresponding to the minimal representation $V$ and $B = e_n$ in the SQCD or the $\mathcal{N} = 2^*$ theory. In the $\mathcal{N} = 2^*$ case, the D6-branes should be omitted, and the O6-plane that intersects an NS5-brane is present in the system but suppressed in the figure. The D4-brane on top of the O6-plane, indicted by the gray line, is present only for the gauge group $\text{SO}(2n + 1)$. (b): a realization of the 't Hooft operator corresponding to $\wedge^2 V$ and $B = e_{n-1} + e_n$. 

2.4 SQMs on 't Hooft operators

So far we have constructed 't Hooft operators in the 4d $\mathcal{N} = 2$ U/SO/USp SQCD or $\mathcal{N} = 2^*$ U/SO/USp gauge theories using branes and orientifolds in type IIA string theory. A physical quantity associated with the 't Hooft operators is the expectation value of their product. The expectation value may or may not contain non-perturbative contributions, namely monopole screening contributions. The brane construction is useful to understand the monopole screening contributions of the 't Hooft operators [10–12].

Let us look at an example of the 4d $\mathcal{N} = 2$ U(2) SQCD with 4 flavors. The brane configuration where we insert two minimal 't Hooft operators with the total magnetic charge $B = -e_1 + e_2$ is depicted in figure 8a. The charge may be screened by a smooth monopole, with the opposite charge, corresponding to a D2-brane stretched between the two D4-branes as in figure 8b. By tuning the positions we can align and combine the three D2-branes as in figure 8c to obtain a single D2-brane between the two NS5'-branes. This configuration corresponds to the monopole screening sector with $v = 0$. Since the D2-brane is also bounded by NS5-branes and NS5'-branes, the theory that lives on the D2-brane realizes a 1d theory, i.e., an SQM, at low energies.

The SQM is the dimensional reduction of a 2d $\mathcal{N} = (0, 4)$ supersymmetric gauge theory [11, 16, 31, 32]. The matter content of the SQM can be read off from fundamental strings connecting D-branes in the configuration. The matter content is summarized as follows.
Figure 8. (a): the NS5'-branes and the D2-branes insert a product ’t Hooft operator with total charge $B = -e_1 + e_2$. (b): we add a D2-brane between the two D4-branes; it represents a smooth monopole. (c): the new D2-brane reconnects with the other D2-branes to form a single D2-brane that only end on NS5'-branes. The system realizes the sector with $v = 0$, where the magnetic charge is screened completely. (d): the $\mathcal{N} = (0, 4)$ quiver diagram for the SQM that lives on the D2-brane in (c).

| $\mathcal{N} = (0, 4)$ multiplet | representation | number |
|----------------------------------|---------------|--------|
| $n$ D2 - $n$ D2                  | vector multiplet | adjoint of U($n$) | 1 |
| $n$ D2 - $n'$ D2                 | hypermultiplet  | bifundamental of U($n$) x U($n'$) | 1 |
| $n$ D2 - $N_c$ D4                | hypermultiplet  | fundamental of U($n$) | $N_c$ |
| $n$ D2 - $N_F$ D6                | short Fermi multiplet | fundamental of U($n$) | $N_F$ |

The leftmost column lists the branes connected by fundamental strings. Each number on the rightmost column is the number of supermultiplets in the representation indicated on the third column. For later use we include a row for the fundamental strings between a stack of D2-branes and another stack of D2-branes that are adjacentely separated by an NS5'-brane. While a short Fermi multiplet has $\mathcal{N} = (0, 4)$ on-shell supersymmetry [31], an $\mathcal{N} = (0, 2)$ subalgebra can be completed off-shell [12]. This is sufficient for SUSY localization.

Let us consider an example in figure 8. The SQM living on the D2-brane in figure 8c can be represented by a quiver diagram in figure 8d. A circular node with an integer $n$ indicates a U($n$) gauge group[12] and the corresponding $\mathcal{N} = (0, 4)$ vector multiplet. A solid line between two circular nodes would be an $\mathcal{N} = (0, 4)$ hypermultiplet in the bifundamental representation. On the other hand a solid line between one circular node and a square node, as appearing in figure 8d, represents as many hypermultiplets in the fundamental representation as the number in the square. A dashed arrow between a circular node and a square node represents short Fermi multiplets in the fundamental representation, with their number shown in the square. The supersymmetric index of the SQM yields the monopole screening contribution [10–14]. We will use this technique to compute ’t Hooft operator correlators in U($N$) gauge theories in section 3.

The same strategy works for the SO/USp SQCD constructed with an O4-plane. The SQM gauge group on the D2-branes is determined by the type of the O4-plane they intersect as follows [33].

[12] If the gauge group is different from $U$-type we will explicitly write the gauge group in a circular node.
An O4$^-$- or O4$^{-}\tilde{\cdot}$-plane requires the number of D2-branes, including the mirror images, to be even ($2n$). An O4$^+$-plane allows it to be an arbitrary positive integer ($n$). We emphasize that the gauge group is the O-type not the SO-type. This will be important when we compare supersymmetric indices with Moyal products.

The SQMs describing monopole screening contributions for 't Hooft operators in $\mathcal{N} = 2^*$ gauge theories may be obtained similarly. In those cases we do not have D6-branes and the SQMs are the dimensional reduction of 2d $\mathcal{N} = (4,4)$ supersymmetric gauge theories [10]. For SQMs from 't Hooft operators in the 4d $\mathcal{N} = 2^*$ U($N$) gauge theory, the fundamental strings between D-branes give supermultiplets as in the following table.

| $\mathcal{N} = (4,4)$ multiplet | representation | number |
|---------------------------------|----------------|--------|
| $n$ D2 - $n$ D2                 | vector multiplet | adjoint of U($n$) | 1 |
| $n$ D2 - $n'$ D2                | hypermultiplet  | bifundamental of U($n$) $\times$ U($n'$) | 1 |
| $n$ D2 - $N_c$ D4               | hypermultiplet  | fundamental of U($n$) | $N_c$ |

An $\mathcal{N} = (4,4)$ vector multiplet consists of an $\mathcal{N} = (0,4)$ vector multiplet and an $\mathcal{N} = (0,4)$ twisted hypermultiplet. An $\mathcal{N} = (4,4)$ hypermultiplet is made from an $\mathcal{N} = (0,4)$ hypermultiplet and an $\mathcal{N} = (0,4)$ (long) Fermi multiplet.

As discussed in section 2.3, we may change the 4d gauge group into SO or USp by introducing O6-planes. The 1d gauge group on the D2-branes which intersect with the O6-plane at $x^6 = 0$ changes due to the effect of the orientifold. The correspondence between the type of the O6-plane and the 1d gauge group is given as follows.

| O6$^-$ | O6$^+$ |
|--------|--------|
| D2     | O($n$) | USp($2n$) |

See for example [16]. The representations for the open strings that connect various D-branes are modified by the presence of an orientifold appropriately.

Let us also summarize the graphical notations we use for SQM quiver diagrams. Throughout this paper we use the notation appropriate for the $\mathcal{N} = (0,4)$ supersymmetry.\textsuperscript{13}

| $\mathcal{N} = (0,4)$ multiplet | symbol               |
|---------------------------------|----------------------|
| vector multiplet                | circle               |
| hypermultiplet                  | straight solid line  |
| twisted hypermultiplet          | wavy solid line      |
| short Fermi multiplet           | dashed line          |
| long Fermi multiplet            | dash-dotted line     |

\textsuperscript{13}In our previous paper [13] we mostly used the $\mathcal{N} = (0,2)$ notation for SQM quiver diagrams.
For a short Fermi multiplet in the fundamental representation of a factor $U(n)$ in the gauge group, we use a dashed line with an arrow pointing toward the $U(n)$ node. See figures 8d and 12c for representative examples.

### 2.5 Extra term in the supersymmetric index

In sections 4 and 5 we will make use of the brane construction and determine the SQMs which describe monopole screening in 4d SO/USp gauge theories. The monopole screening contributions are given by certain supersymmetric indices of the SQMs. In fact there is a subtlety in the supersymmetric index computations. What we here call the “supersymmetric index” is either a quantity obtained by the JK residue prescription applied to the poles away from infinities, or such a quantity modified by the “extra term” prescription below. We will use this nomenclature throughout this paper. We refer to appendix 2.2 of [13] for a summary of the JK residue prescription.

Supersymmetric indices of SQMs are not only used for monopole screening contributions in expectation values of ’t Hooft operators but also used for instanton partition functions of 5d gauge theories that are ultraviolet (UV) complete. In those cases, the SQMs are the ADHM gauged quantum mechanics. Then the sum of the supersymmetric indices of the SQMs weighted by instanton fugacities basically yields the 5d instanton partition function. Sometimes, however, typically when the number of flavors in the 5d theory is large, it has turned out that one needs to factor out an extra factor from the instanton partition function [16, 34–37]. Namely in general we have

\[
1 + \sum_{k=1}^{\infty} u^k Z_{\text{SQM},k} = Z_{5d\ \text{inst}} Z_{\text{extra}},
\]

(2.4)

where the lefthand side is the sum of the supersymmetric indices of the AHDM quantum mechanics with the instanton fugacity $u$, $Z_{5d\ \text{inst}}$ is the 5d instanton partition function and $Z_{\text{extra}}$ is the extra factor. The extra factor contribution is decoupled from the 5d dynamics and may be quantitatively characterized as a factor which is independent of Coulomb branch moduli. The two factors $Z_{5d\ \text{inst}}$ and $Z_{\text{extra}}$ themselves can be expanded by the instanton fugacity $u$ as

\[
Z_{5d\ \text{inst}} = 1 + \sum_{k=1}^{\infty} Z_{5d\ \text{inst},k} u^k,
\]

(2.5)

\[
Z_{\text{extra}} = 1 + \sum_{k=1}^{\infty} Z_{\text{extra},k} u^k.
\]

(2.6)

Then (2.4) becomes

\[
1 + u Z_{\text{SQM},1} + \cdots = 1 + u \left( Z_{5d\ \text{inst},1} + Z_{\text{extra},1} \right) + \cdots,
\]

(2.7)

and in particular we have

\[
Z_{5d\ \text{inst},1} = Z_{\text{SQM},1} - Z_{\text{extra},1}.
\]

(2.8)

The one-instanton part of $Z_{5d\ \text{inst}}$ is obtained by subtracting the Coulomb branch moduli independent part of $Z_{\text{SQM},1}$.
In fact the instanton partition function is not completely unrelated to a monopole screening contribution in expectation values of ’t Hooft operators. For example, in [9, 10], a monopole screening contribution of ’t Hooft operators in the 4d $\mathcal{N} = 2^*$ U(N) or SU(N) gauge theory was obtained by using a part of the 5d instanton partition function of the 5d $\mathcal{N} = 1^*$ U(N) or SU(N) gauge theory. The relation is indeed expected from the Kronheimer correspondence [15]. Since we remove an extra factor from the 5d instanton partition function it is natural also to remove the corresponding part from the supersymmetric indices of SMQs describing monopole screening contributions.

Based on the observation we propose that we need to remove a part which is independent of the 4d Coulomb branch moduli from the supersymmetric indices of SQMs describing monopole screening for irreducible ’t Hooft operators which arises from a single D2-brane in asymptotically free or superconformal theories. In this case we subtract, rather than factor out, a Coulomb branch moduli independent term due to the relation (2.8) and we will call it an “extra term”. Since (2.8) is valid for the one-instanton part the prescription is restricted to ’t Hooft operators from a single D2-brane. To extract the extra term we move deep inside a Weyl chamber of Cartan scalars in the 4d $\mathcal{N} = 2$ vector multiplets where the exponentiated Coulomb branch moduli become good expansion parameters. Then we expand a monopole screening contribution by the Coulomb branch moduli and the extra term is given by the zeroth order of the expansion parameters. Considering a different Weyl chamber will give a gauge equivalent result. For $\mathcal{N} = 2^*$ theories we do not subtract the whole Coulomb branch independent term but leave the number of zero weights for $\nu = 0$ sectors so that the $\mathcal{N} = 4$ limit reproduces the character of the representation under consideration.

In fact the extra term we determine by our prescription captures the Coulomb branch contribution to the ground state index of the SQM considered for the 4d $\mathcal{N} = 2$ SU(2) gauge theory with four flavors in [12]. The monopole screening contribution in the product of the two minimal ’t Hooft operators of the U(2) gauge theory with four flavors is given

---

14See also [38] for a work that demonstrates the relation between monopole screening contributions in 4d and 5d instanton partition functions on ALE spaces.
15For $\mathcal{N} = 2^*$ theories, irreducible ’t Hooft operators are those which are S-dual to Wilson operators in irreducible representations.
16We will not apply this prescription to monopole screening contributions of U(N) gauge theories in section 3 as they are not UV complete.
17What we call the Coulomb branch moduli are the coefficients $a_i$ in the sum $\sum_i a_i e_i$, which is a complex combination of the vev an adjoint scalar and the gauge holonomy along $S^1$. The conjugate parameters $b_i$ are the coefficients in the sum $\sum_i b_i e_i$, which is a complex combination of the vev of another adjoint scalar and the chemical potential for the magnetic charge $v$. The ’t Hooft operator vevs depend on $a_i$ and $b_i$, as well as the $\Omega$-deformation parameter $\epsilon_+$ and the mass parameters ($m_f$ for SQCD and $m$ for the $\mathcal{N} = 2^*$ theory). See [9] for the precise definitions. In this paper we use the convention of our previous paper [13].
18When $Z_{\text{extra}, 1} = 0$, then (2.7) gives

$$Z_{\text{5d inst}, 2} = Z_{\text{SQM}, 2} - Z_{\text{extra}, 2}.$$ (2.9)

Hence we can also simply subtract the Coulomb branch independent term in this case also. We will see this type of examples in section 5.2.2 and in appendix C.2.1.
by the supersymmetric index of the SQM in figure 8d. The result becomes [9, 12–14]

\[ Z_{\text{SQM}}(a_1, a_2) = -\frac{\prod_{f=1}^{4} 2 \sinh \frac{a_1 - m_f - \epsilon_+}{2}}{2 \sinh \frac{a_1 - a_2 - 2\epsilon_+}{2}} - \frac{\prod_{f=1}^{4} 2 \sinh \frac{a_2 - m_f - \epsilon_+}{2}}{2 \sinh \frac{a_1 - a_2 + 2\epsilon_+}{2}}, \]  

(2.10)

when the Fayet-Iliopoulos (FI) parameter associated to the U(1) gauge group is positive.

To apply the extra term prescription to SU(2) gauge group we set \( a := a_1 = -a_2 \). The Coulomb branch moduli independent part is

\[ Z_{\text{extra}} = -2 \cosh \left( \sum_{f=1}^{4} m_f + \epsilon_+ \right). \]

(2.11)

Then subtracting the extra term yields

\[ Z_{\text{SQM}}(a, -a) - Z_{\text{extra}} = -\frac{\prod_{f=1}^{4} 2 \sinh \frac{a_1 - m_f - \epsilon_+}{2}}{2 \sinh \frac{a_1 - a_2 - 2\epsilon_+}{2}} + \frac{\prod_{f=1}^{4} 2 \sinh \frac{a_2 - m_f - \epsilon_+}{2}}{2 \sinh \frac{a_1 - a_2 + 2\epsilon_+}{2}} + 2 \cosh \left( \sum_{f=1}^{4} m_f + \epsilon_+ \right), \]

(2.12)

which reproduces the result in [12, 14], and also is consistent with the CFT result using the AGT correspondence [9]. This analysis gives support for the extra term prescription.

In section 4 and section 5, we will apply this prescription for SQMs which arise in SO and USp gauge theories. In fact the monopole screening contribution in the expectation value of the 't Hooft operator in the rank-2 anti-symmetric representation of the Langlands dual group in 4d \( \mathcal{N} = 2 \) SO/USp SQCD has another subtlety. We will comment on the subtlety in appendix C and circumvent the issue by choosing the number of flavors to be small enough.

### 2.6 Wall-crossing and operator ordering

In [13] we studied, for the U(\(N\)) SQCD with \(N_F = 2N\) flavors, the expectation value of the product of several 't Hooft operators with minimal charges

\[ T_B = T_1(s_1) \cdot T_2(s_2) \cdot \ldots \cdot T_\ell(s_\ell) \quad \text{in path integral.} \]

(2.13)

Minimal charges refer to those which correspond to the fundamental or anti-fundamental representation of the Langlands dual of the gauge group, which is again U(\(N\)). Let \((x^1, x^2, x^3)\) be the Cartesian coordinates of \(\mathbb{R}^3\). An \(\Omega\)-deformation in the \((x^1, x^2)\)-space (with parameter \(\epsilon_+\)) requires \(T_a\)’s to be on the 3-axis \((x^1 = x^2 = 0)\). The parameter \(s_a\) in (2.13) is the \(x^3\)-value \((x^3 = s_a)\) of the \(a\)-th operator, and we assume that \(s_a\)’s are distinct. The expectation value of (2.13) depends only on the ordering of \(s_a\)’s. If we regard \(x^3\) as the Euclidean time, the ordering of \(s_a\)’s specified by a permutation \(\sigma \in \mathcal{S}_\ell\) as

\[ s_{\sigma(1)} > s_{\sigma(2)} > \ldots > s_{\sigma(\ell)} \]

(2.14)

is equivalent to the time ordering of \(\hat{T}_a\)’s in canonical quantization

\[ \hat{T}_{\sigma(1)} \cdot \hat{T}_{\sigma(2)} \cdot \ldots \cdot \hat{T}_{\sigma(\ell)}. \]

(2.15)
The SQMs that describe monopole screening in the product of \( \ell \) operators have unitary gauge groups and the corresponding FI parameters \( \zeta = (\zeta_a)_{a=1}^{\ell-1} \) related to the positions as \( \zeta_a = s_{a+1} - s_a \) \( (a = 1, \ldots, \ell - 1) \) \footnote{As we vary \( \zeta \) some SQMs exhibit wall-crossing, i.e., a discrete change occurs in the supersymmetric index. As shown in \cite{10} the expectation value of the product of (general) ‘t Hooft operators is equal to the Moyal product of the expectation values of individual operators:}

\[
\langle T_1 \cdot T_2 \cdot \ldots \cdot T_\ell \rangle = \langle T_{\sigma(1)} \rangle \ast \langle T_{\sigma(2)} \rangle \ast \ldots \ast \langle T_{\sigma(\ell)} \rangle.
\] (2.16)

The possible dependence on the ordering of \( s_a \)’s is realized by the non-commutativity of the Moyal product, which is associative and is defined as\footnote{The definition (2.17) assumes that \( a_i \) and \( b_i \) are the coefficients in the expansions \( a = \sum a_i e_i, \ b = \sum b_i e_i \) with respect to an orthonormal basis \( \{ e_i \} \) of the Cartan subalgebra.}

\[
(f \ast g)(a, b) = \exp \left[ -\epsilon_+ \sum_{k=1}^{\text{rank} G} \left( \partial_{b_k} \partial_{a_k'} - \partial_{a_k} \partial_{b_k'} \right) \right] f(a, b) g(a', b') \bigg|_{a_k=a_k'=b_k=b_k'}. \tag{2.17}
\]

Non-commutativity of the Moyal product as well as the brane construction of ‘t Hooft operators suggest that wall-crossing is associated with a change in the ordering of operators. In \cite{13} we made the following conjectures for minimal operators in \( U(N) \) theories:

1. The supersymmetric indices of the SQMs coincide with the \( Z_{\text{mono}} \)’s read off from the Moyal products.
2. Wall-crossing can occur in the SQMs only across the walls in the space of FI parameters where the ordering of distinct operators changes.

By explicit calculations, we confirmed the conjectures for the correlators involving up to three minimal operators.\footnote{The relation between wall-crossing and operator ordering was extended to monopole operators in three-dimensional \( \mathcal{N} = 4 \) quiver gauge theories involving unitary gauge groups \cite{39, 40}.}

Based on earlier discussions of this section we make modified versions of conjecture (i).

As we saw in section 2.4, the brane constructions of some types of ‘t Hooft operators in \( \mathcal{N} = 2 \ U/\text{SO}/\text{USp} \) SQCD or \( \mathcal{N} = 2^* \ U/\text{SO}/\text{USp} \) gauge theories naturally give rise to SQMs that capture monopole screening effects. In section 2.5 we proposed, for \( \text{SO}/\text{USp} \) theories, a prescription for computing the monopole screening contributions \( Z_{\text{mono}} \) using the SQMs, up to the subtleties to be discussed in appendix C. We make the following conjectures.

1. For the SQCD and the \( \mathcal{N} = 2^* \) theory with gauge group \( U(N) \), and for the product of the operators with minuscule magnetic charges corresponding to \( \wedge^k V \) or \( \wedge^k \overline{V} \), the \( Z_{\text{mono}} \)’s computed as the supersymmetric indices by the JK prescriptions coincide with those read off from the Moyal products.
2. For the SQCD and the \( \mathcal{N} = 2^* \) theory with gauge group \( \text{SO}(N) \) or \( \text{USp}(N) \), the correct \( Z_{\text{mono}} \)’s can be computed from the SQMs according to the extra term prescription formulated in section 2.5, up to the subtleties discussed in appendix C.

We will provide evidence for (i)” in section 3, and for (i)” in sections 4 and 5.
Figure 9. (a) The brane configuration for an ’t Hooft loop with $B = e_N + e_{N-1} - e_1 - e_2$. (b) A D2-brane suspended between two D4-branes is introduced to describe ’t Hooft-Polyakov monopole which screen the magnetic charge. (c) After D2-brane moves with Hanany-Witten effects, we obtain a brane configuration for the SQM with $v = e_N - e_1$.

We also make conjecture (ii)', which says that in the U(N) SQCD the statement of (ii) holds for the operators $T_a$’s in (i)’. We will explicitly check this for some examples in section 3.1. We will discuss wall-crossing in the SO/USp gauge groups in section 6 and appendix C.

3 ’t Hooft operators with higher charges in U(N) gauge theories

In this section we study the ’t Hooft operators with non-minimal charges in the U(N) SQCD and the U(N) $\mathcal{N} = 2^*$ theory. In section 3.1 we focus on the SQCD and compute some of the correlation functions involving non-minimal ’t Hooft operators, confirming the conjectures (i)’ and (ii)’ in section 2.6 in these examples. In section 3.2 we repeat the analysis for the $\mathcal{N} = 2^*$ theory.

3.1 $\mathcal{N} = 2$ SQCD

We consider the 4d U(N) gauge theory with $2N$ hypermultiplets in the fundamental representation. The minimal ’t Hooft line operator is either in the fundamental representation $V$, or in the anti-fundamental representation $\bar{V}$, both of the Langlands dual of the gauge group U(N), which is again U(N). The Moyal products of the minimal ’t Hooft operators were studied in [13]. Here we consider products of non-minimal ’t Hooft operators.

3.1.1 $\wedge^2 V$ and $\wedge^2 \bar{V}$

An example of a non-minimal operator is the ’t Hooft operator $T_{\wedge^2 V} := T_{B=e_{N-1}+e_N}$ in the rank-2 anti-symmetric representation $\wedge^2 V$. (See appendix A for useful facts about Lie algebras.) Its expectation value on $S^1 \times \mathbb{R}^3$ is determined by the localization formula (B.1) and is given in terms of one-loop determinants as

$$\langle T_{\wedge^2 V} \rangle = \sum_{1 \leq i < j \leq N} e^{a_i + b_j} Z_{ij}(a),$$

(3.1)
where\footnote{Throughout the paper, we use the short-hand notation $2\sinh \frac{a_i-a_f}{2} \sinh \frac{a_j-a_f}{2} \prod_{1 \leq k \neq i,j \leq N} 2 \sinh \frac{a_i-a_k+\epsilon_+}{2} \sinh \frac{a_k-a_i+\epsilon_+}{2}$.}

\begin{equation}
Z_{ij}(a) = \left( \prod_{f=1}^{2N} \frac{2 \sinh \frac{a_i-a_f}{2} \sinh \frac{a_j-a_f}{2}}{2 \sinh \frac{a_i-a_f+\epsilon_+}{2} \sinh \frac{a_j-a_f+\epsilon_+}{2}} \right)^{\frac{1}{2}}.
\end{equation}

The expectation value of the 't Hooft line operator $T_{A^2V}$ in the representation $\wedge^2 V$ is

\begin{equation}
\langle T_{A^2V} \rangle = \sum_{1 \leq i < j \leq N} e^{-b_i - b_j} Z_{ij}(a).
\end{equation}

### 3.1.2 $\wedge^2 V \times \wedge^2 V$

Let us consider the product of $T_{A^2V}$ and $T_{A^2V}$. The Moyal product of the vevs may depend on the order because the two operators are distinct. The product in one order is given by

\begin{equation}
\langle T_{A^2V} \rangle \ast \langle T_{A^2V} \rangle = \sum_{1 \leq h \leq N, 1 \leq i < j \leq N} e^{b_i+b_j+b_h} Z_{hi}(a - \epsilon_+ (e_j + e_h)) Z_{jk}(a - \epsilon_+ (e_i + e_k))
+ \sum_{1 \leq h \neq N, 1 \leq i \neq j \leq N} e^{b_i+b_j+b_h} Z_{ih}(a - \epsilon_+ (e_j + e_i)) Z_{jk}(a - \epsilon_+ (e_h + e_k))
+ \sum_{1 \leq i < j \leq N} Z_{ij}(a - \epsilon_+ (e_i + e_j))^2.
\end{equation}

and the product in the other order by

\begin{equation}
\langle T_{A^2V} \rangle \ast \langle T_{A^2V} \rangle = \sum_{1 \leq h \leq N, 1 \leq i < j \leq N} e^{b_i+b_j+b_h} Z_{hi}(a + \epsilon_+ (e_j + e_h)) Z_{jk}(a + \epsilon_+ (e_i + e_k))
+ \sum_{1 \leq h \neq N, 1 \leq i \neq j \leq N} e^{b_i+b_j+b_h} Z_{ih}(a + \epsilon_+ (e_j + e_i)) Z_{jk}(a + \epsilon_+ (e_h + e_k))
+ \sum_{1 \leq i < j \leq N} Z_{ij}(a + \epsilon_+ (e_i + e_j))^2.
\end{equation}

In each of these expressions there are two types of monopole screening contribution for the unscreened charge $B = e_{N-1} + e_N - e_1 - e_2$: one characterized by the screened charge $v = e_i - e_j$ and the other by $v = 0$.

$v = e_i - e_j$ (i $\neq$ j). We first consider the monopole screening contributions in the sector $v = e_i - e_j$. In (3.4), such a contribution can be read off by writing

\begin{equation}
e^{b_i - b_j} \sum_{1 \leq k \neq i,j \leq N} Z_{ik}(a - \epsilon_+ (e_j + e_k)) Z_{jk}(a - \epsilon_+ (e_i + e_k))
= e^{b_i - b_j} Z_{1\text{-loop}}(v = e_i - e_j) Z_{\text{mono}}^{\wedge^2 V \times \wedge^2 V}(v = e_i - e_j),
\end{equation}

where the one-loop part is

\begin{equation}
Z_{1\text{-loop}}(v = e_i - e_j)
= \left( \prod_{f=1}^{2N} \frac{2 \sinh \frac{a_i-a_f}{2} \sinh \frac{a_j-a_f}{2}}{2 \sinh \frac{a_i-a_f+\epsilon_+}{2} \sinh \frac{a_j-a_f+\epsilon_+}{2}} \right)^{\frac{1}{2}}.
\end{equation}
the residues are to be evaluated at 
\[ \zeta > 0 \]
to the quiver diagram in figure 10a. Its supersymmetric index is 
from the D-brane configuration shown in figure 9c. For general 
The two expressions (3.8) and (3.10) are similar but not obviously equal to each other.

Similarly, for \( \langle T_{\lambda^2} \rangle * \langle T_{\lambda^2} \rangle \), we rewrite a part of the second line in (3.5) as 
\[ e^{b_i - b_j} \sum_{1 \leq k \neq i,j \leq N} Z_{ik}(a + \epsilon_+ (e_j + e_k))Z_{jk}(a + \epsilon_+(e_i + e_k)) \]
where the one-loop part is again (3.7). The monopole screening contribution in this case is 
\[ Z_{\text{mono}}^{\lambda^2 \times \lambda^2}(v = e_i - e_j) = \sum_{1 \leq k \neq i,j \leq N} \prod_{j=1}^{2N} 2 \sinh \frac{a_k - m_f - \epsilon_+}{2} \prod_{1 \leq k \neq i,j,k \leq N} 2 \sinh \frac{a_k - a_i + \epsilon_+}{2} \frac{a_k + a_j + \epsilon_+}{2} \] (3.10)
The two expressions (3.8) and (3.10) are similar but not obviously equal to each other.

We now compare the expressions with the supersymmetric index of the SQM for the \( v = e_i - e_j \) sector of \( T_{e_{N-1} + e_{N-1} - e_1 + e_2} \). The SQM specialized to \( i = N, j = 1 \) can be read off from the D-brane configuration shown in figure 9c. For general \( i \neq j \) the SQM corresponds to the quiver diagram in figure 10a. Its supersymmetric index is 
\[ Z(v = e_i - e_j, \zeta) = \oint_{JK(\zeta)} \frac{d\phi}{2\pi i} \frac{2 \sinh(\epsilon_+) \prod_{f=1}^{2N} 2 \sinh \frac{\phi - m_f}{2} \prod_{1 \leq k \neq i,j \leq N} 2 \sinh \frac{\phi - a_k + \epsilon_+}{2} \frac{\phi + a_j + \epsilon_+}{2}} {2N \sinh \frac{a_k + \epsilon_+}{2}} \] (3.11)
For \( \zeta > 0 \) the JK residue prescription, summarized in appendix 2.2 of [13], instructs us to evaluate the residues at the poles \( \phi = a_k - \epsilon_+ \) with \( k \neq i,j \). For \( \zeta < 0 \), on the other hand, the residues are to be evaluated at \( \phi = a_k + \epsilon_+ \) with \( k \neq i,j \). This gives 
\[ Z_{\text{mono}}^{\lambda^2 \times \lambda^2}(v = e_i - e_j) = Z(v = e_i - e_j, \zeta > 0), \]
\[ Z_{\text{mono}}^{\lambda^2 \times \lambda^2}(v = e_i - e_j) = Z(v = e_i - e_j, \zeta < 0). \] (3.12)
For the SQM is in figure 10b. The supersymmetric index of the quiver theory is by the last lines of (3.4) and (3.5), Such contributions in the Moyal products $= 0$ It can be checked that there occurs wall-crossing. 22

$\nu \neq 0$. We next consider the monopole screening contributions from the sector $\nu = 0$. Such contributions in the Moyal products $\langle T_{\nu} T_{\nu} \rangle$ and $\langle T_{\nu} T_{\nu} \rangle * \langle T_{\nu} T_{\nu} \rangle$ are given by the last lines of (3.4) and (3.5),

$$Z_{\text{mono}}^{\lambda^2 V \times \lambda^2 V}(\nu = 0) = \sum_{1 \leq i < j \leq N} \prod_{1 \leq i < j \leq N} \frac{\prod_{i=1}^{2N} \sin \frac{\alpha_i - m_j - \epsilon_j}{2}}{2 \sin \frac{\alpha_i - m_j - \epsilon_j}{2}}, \quad (3.13)$$

$$Z_{\text{mono}}^{\lambda^2 V \times \lambda^2 V}(\nu = 0) = \sum_{1 \leq i < j \leq N} \prod_{1 \leq i < j \leq N} \frac{\prod_{i=1}^{2N} \sin \frac{\alpha_i - m_j + \epsilon_j}{2}}{2 \sin \frac{\alpha_i - m_j + \epsilon_j}{2}}, \quad (3.14)$$

The D-brane configuration for $\nu = 0$ is depicted in figure 11, and the quiver diagram for the SQM is in figure 10b. The supersymmetric index of the quiver theory is

$$Z(\nu = 0, \zeta) = \frac{1}{2} \oint_{\gamma(K)} \frac{d\phi_1}{2\pi i} \frac{d\phi_2}{2\pi i} \prod_{1 \leq i \neq j \leq 2} \sin \frac{\phi_i - \phi_j}{2}$$

$$\times (2 \sin \epsilon_+)^2 \left( \prod_{1 \leq i \neq j \leq 2} 2 \sin \frac{\phi_i - \phi_j + \epsilon_+}{2} \right) \left( \prod_{i=1}^{2N} \prod_{j=1}^{2N} 2 \sin \frac{\phi_i - m_j}{2} \right). \quad (3.15)$$

For $\zeta > 0$ the JK residues are evaluated at

$$\{ \phi_i - a_i + \epsilon = 0 \} \cap \{ \phi_j - a_j + \epsilon = 0 \} \text{ for } i, j = 1, 2, \ldots, N, \quad (3.16)$$

and for $\zeta < 0$ at

$$\{ -\phi_i + a_i + \epsilon = 0 \} \cap \{ -\phi_j + a_j + \epsilon = 0 \} \text{ for } i, j = 1, 2, \ldots, N, \quad (3.17)$$

giving the relations

$$Z_{\text{mono}}^{\lambda^2 V \times \lambda^2 V}(\nu = 0) = Z(\nu = 0, \zeta > 0), \quad Z_{\text{mono}}^{\lambda^2 V \times \lambda^2 V}(\nu = 0) = Z(\nu = 0, \zeta < 0). \quad (3.18)$$

22The SQM and the contour integral (3.11) are in fact identical to those which appear for the product of $T_{\nu}$ and $T_{\nu}$ in the $U(N-2)$ SQCD with $2N$ flavors. See (3.17) of [13]. It follows, from the discussion in section 5 there, that for the $U(N)$ SQCD with $N_F$ flavors, $T_{\nu}$ and $T_{\nu}$ exhibit wall-crossing for $N_F \geq 2N - 2$.  

Figure 11. (b) two D2-brane suspended between D4-branes are introduced to describe 't Hooft-Polyakov monopole which screen the magnetic charge. (c) After Hanany-Witten effects, we obtain a brane configuration for the SQM with $\nu = 0$. It can be checked that there occurs wall-crossing. 22
Figure 12. (a) The brane configuration for an ‘t Hooft loop with magnetic charge $B = e_N - e_1$. (b) A D2-brane suspended between two D4-branes is introduced to describe ‘t Hooft-Polyakov monopole with magnetic charge $v = -e_N + e_1$. When the vertical position of three segments of D2-branes coincide, the D2-branes combined into single D2-brane suspended between two NS5’-branes. Then the magnetic charge are completely screened. (c) The quiver diagram for SQM for the D2-brane world volume theory of (b). The solid line denotes 1d hypermultiplets. The dash-dotted line denotes long Fermi multiplets. The wavy line denotes a free twisted hypermultiplet.

For small values of $N$ we checked that wall-crossing occurs between the positive and negative values of $\zeta$. We obtain the relations

$$
\langle T_{e_{N-1} + e_N - e_1 - e_2} \rangle^{(\zeta > 0)} = \langle T_{A^2V} \rangle \ast \langle T_{A^2V} \rangle,
$$

$$
\langle T_{e_{N-1} + e_N - e_1 - e_2} \rangle^{(\zeta < 0)} = \langle T_{A^2V} \rangle \ast \langle T_{A^2V} \rangle.
$$

(3.19)

Here $\langle \bullet \rangle^{(\zeta > 0)}$ (resp. $\langle \bullet \rangle^{(\zeta < 0)}$) expresses the vev of the ‘t Hooft operator with the supersymmetric indices evaluated in the region $\zeta > 0$ (resp. $\zeta < 0$).

3.2 $\mathcal{N} = 2^*$ theory

It is also possible to consider monopole screening contributions in the expectation values of ‘t Hooft operators of the 4d $\mathcal{N} = 2^*$ U($N$) gauge theory by utilizing the brane construction reviewed in section 2.1. Then we can repeat the analysis which we have done in section 3.1.

3.2.1 $V \times \overline{V}$

For the $\mathcal{N} = 2^*$ theory we begin with the product of the minimal ‘t Hooft operators, repeating the analysis we did for the SQCD in [13].

The vevs $\langle T_V \rangle$ and $\langle T_{\overline{V}} \rangle$ are determined by the one-loop determinants (B.3) and (B.4) as

$$
\langle T_V \rangle = \sum_{i=1}^{N} e^{b_i} Z_i(a), \quad \langle T_{\overline{V}} \rangle = \sum_{i=1}^{N} e^{-b_i} Z_i(a),
$$

(3.20)

with

$$
Z_i(a) = \left( \prod_{k=1}^{N} \frac{\sinh \frac{a_i - a_k - m}{2} \sinh \frac{a_k - a_i - m}{2}}{\sinh \frac{a_i - a_k + \epsilon_+}{2} \sinh \frac{a_k - a_i + \epsilon_+}{2}} \right)^{1/2}.
$$

(3.21)
Using the definition (2.17) of the Moyal product we get

\[
\langle T_V \rangle \ast \langle T_{\bar{V}} \rangle = \sum_{1 \leq i \neq j \leq N} e^{b_{i} - b_{j}} Z_{1\text{-loop}}(a, v = e_{i} - e_{j}) + Z_{V \times \bar{V}}(a, v = 0; \epsilon_{+}),
\]

(3.22)

\[
\langle T_{\bar{V}} \rangle \ast \langle T_V \rangle = \sum_{1 \leq i \neq j \leq N} e^{b_{i} - b_{j}} Z_{1\text{-loop}}(a, v = e_{i} - e_{j}) + Z_{V \times \bar{V}}(a, v = 0; -\epsilon_{+}),
\]

(3.23)

with \(Z_{V \times \bar{V}}\) given as

\[
Z_{V \times \bar{V}}(a, v = 0; \epsilon_{+}) = \sum_{i=1}^{N} \prod_{k \neq i}^{N} 2 \text{sinh} \left( \frac{a_{i} - a_{k} - m - \epsilon_{+}}{2} \right) 2 \text{sinh} \left( \frac{a_{k} - a_{i} + m + \epsilon_{+}}{2} \right) \text{sinh} \left( \frac{a_{k} - a_{i} + 2\epsilon_{+}}{2} \right). 
\]

(3.24)

Next we evaluate the monopole screening contribution in \(\langle T_{B=e_{i} - e_{j}} \rangle\) using an SQM. The D-brane configuration for the reduced magnetic charge \(v = 0\) is shown in figure 12b. The corresponding \(N = (0,4)\) quiver diagram is depicted in figure 12c. The localization formula for the supersymmetric index gives

\[
Z(v = 0, \zeta) = - \oint_{JK(\zeta)} \frac{d\phi}{2\pi i} 2\text{sinh} \frac{\epsilon_{+}}{2} \prod_{i=1}^{N} 2 \text{sinh} \left( \frac{\pm(\phi - a_{i}) - m}{2} \right) \frac{\text{sinh} \left( \frac{\pm(\phi - a_{i}) + m}{2} \right)}{2 \text{sinh} \left( \frac{\pm(\phi - a_{i}) + \epsilon_{+}}{2} \right)}.
\]

(3.25)

Here we chose the overall sign by hand, to obtain a match with the Moyal product below. The JK residues are evaluated at the poles \(\phi = a_{i} - \epsilon\) for \(\zeta > 0\), and at the poles \(\phi = a_{i} + \epsilon\) for \(\zeta < 0\), both with \(i = 1, \cdots, N\). This gives

\[
Z(v = 0, \zeta > 0) = \sum_{i=1}^{N} \prod_{k \neq i}^{N} 2 \text{sinh} \left( \frac{a_{i} - a_{k} - m - \epsilon_{+}}{2} \right) 2 \text{sinh} \left( \frac{a_{k} - a_{i} + m + \epsilon_{+}}{2} \right) \text{sinh} \left( \frac{a_{k} - a_{i} + 2\epsilon_{+}}{2} \right),
\]

(3.26)

\[
Z(v = 0, \zeta < 0) = \sum_{i=1}^{N} \prod_{k \neq i}^{N} 2 \text{sinh} \left( \frac{a_{i} - a_{k} - m + \epsilon_{+}}{2} \right) 2 \text{sinh} \left( \frac{a_{k} - a_{i} - m - \epsilon_{+}}{2} \right) \text{sinh} \left( \frac{a_{k} - a_{i} - 2\epsilon_{+}}{2} \right).
\]

(3.27)

We see that the supersymmetric indices (3.26) and (3.27) agree with the monopole screening contributions read off from the Moyal products (3.22) and (3.23). The residues at \(\text{Re} \phi = \pm \infty\) in (3.25) cancel each other and we have \(Z(\zeta > 0) = Z(\zeta < 0)\): there is no wall-crossing.

We have the relations

\[
\langle T_V \rangle \ast \langle T_{\bar{V}} \rangle = \langle T_{\bar{V}} \rangle \ast \langle T_V \rangle = \langle T_{e_{N} - e_{1}} \rangle.
\]

(3.28)

### 3.2.2 \(\bigwedge^{2} V \times \bigwedge^{2} \bar{V}\)

Next we study monopole screening for \(T_{e_{N} - 1 + e_{N} - e_{1} - e_{2}}\). The vevs of the ’t Hooft operators in the rank-2 anti-symmetric representations are given as

\[
\langle T_{\bigwedge^{2} V} \rangle = \sum_{1 \leq i,j \leq N} e^{b_{i} + b_{j}} Z_{ij}(a), \quad \langle T_{\bigwedge^{2} \bar{V}} \rangle = \sum_{1 \leq i,j \leq N} e^{-b_{i} - b_{j}} Z_{ij}(a)
\]

(3.29)

with

\[
Z_{ij}(a) = \prod_{l=i,j}^{1} \prod_{k=1}^{N} \left( \frac{\text{sinh} \left( \frac{a_{l} - a_{k} - m}{2} \right) \text{sinh} \left( \frac{a_{k} - a_{l} - m}{2} \right)}{\text{sinh} \left( \frac{a_{l} - a_{k} + \epsilon_{+}}{2} \right) \text{sinh} \left( \frac{a_{k} - a_{l} + \epsilon_{+}}{2} \right)} \right)^{\frac{1}{2}}.
\]

(3.30)
Their Moyal products are

\[
\langle T_{\lambda V} \rangle \ast \langle T_{\lambda V} \rangle = \sum_{1 \leq i < j \leq N, 1 \leq l \leq N} e^{b_i + b_j - b_k - b_l} Z_{1\text{-loop}}(a, v = e_i + e_j - e_k - e_l)
\]

\[
\ast \sum_{1 \leq i \neq j \leq N} e^{b_i - b_j} Z_{1\text{-loop}}(a, v = e_i - e_j) Z_{\lambda^2 V \times \lambda^2 V}^{\text{mono}}(a, v = e_i - e_j; \epsilon_+) + \sum_{1 \leq i \neq j \leq N} e^{b_i - b_j} Z_{1\text{-loop}}(a, v = e_i - e_j) Z_{\lambda^2 V \times \lambda^2 V}^{\text{mono}}(a, v = e_i - e_j; -\epsilon_+)
\]

\[
(3.31)
\]

\[
\langle T_{\lambda V} \rangle \ast \langle T_{\lambda V} \rangle = \sum_{1 \leq i < j \leq N, 1 \leq l \leq N} e^{b_i + b_j - b_k - b_l} Z_{1\text{-loop}}(a, v = e_i + e_j - e_k - e_l)
\]

\[
\ast \sum_{1 \leq i \neq j \leq N} e^{b_i - b_j} Z_{1\text{-loop}}(a, v = e_i - e_j) Z_{\lambda^2 V \times \lambda^2 V}^{\text{mono}}(a, v = e_i - e_j; \epsilon_+). (3.32)
\]

Here \(Z_{\lambda^2 V \times \lambda^2 V}^{\text{mono}}(a, v; \epsilon_+)\) are given by

\[
Z_{\lambda^2 V \times \lambda^2 V}^{\text{mono}}(a, v = e_i - e_j; \epsilon_+) = \sum_{i \neq j} \frac{N}{k=1} \prod_{l \neq i, j} 2 \sinh \frac{a_l - a_k}{2} \sinh \frac{a_k - a_l - \epsilon_+}{2} \sinh \frac{a_k - a_l + \epsilon_+}{2} \sinh \frac{a_k - a_l + 2\epsilon_+}{2}
\]

(3.33)

with \(i \neq j\), and

\[
Z_{\lambda^2 V \times \lambda^2 V}^{\text{mono}}(a, v = 0; \epsilon_+) = \sum_{1 \leq i < j} \prod_{k=1}^{N} \prod_{k \neq i, j} 2 \sinh \frac{a_l - a_k}{2} \sinh \frac{a_k - a_l - \epsilon_+}{2} \sinh \frac{a_k - a_l + \epsilon_+}{2} \sinh \frac{a_k - a_l + 2\epsilon_+}{2}
\]

(3.34)

We now compare these expressions with the supersymmetric indices of the SQMs.

\(v = e_i - e_j\). The D-brane configuration for the monopole screening sector \(v = e_i - e_j\) would be represented by the same figure as figure 9c except that the dashed lines for the D6-branes should be omitted. The resulting SQM on the D2-branes has the \(N = (4,4)\)
supersymmetry. Its quiver diagram in the \( N = (0,4) \) notation is given in figure 13a. The localization formula for the supersymmetric index gives

\[
Z(\mathbf{v} = \mathbf{e}_{N-1} - \mathbf{e}_2, \zeta) = - \oint_{JK(\zeta)} \frac{d\phi_1}{2\pi i} \frac{d\phi_2}{2\pi i} \left( \frac{2 \sinh \epsilon_+}{2 \sinh \frac{m-\epsilon_+}{2}} \right)^2 \prod_{l=2}^{N-1} 2 \sinh \frac{a_l-a_{l-1} - m + \epsilon_+}{2} \sinh \frac{a_{l-1} + 2 \epsilon_+}{2}.
\]  

(3.35)

Again the overall sign is fixed by hand. The JK residues for (3.40) and (3.41) turn out to vanish, and the supersymmetric index

\[
Z(\mathbf{v} = \mathbf{e}_{N-1} - \mathbf{e}_2, \zeta) > 0 = \sum_{l=2}^{N-1} \prod_{k \neq l} 2 \sinh \frac{a_l-a_k - m + \epsilon_+}{2} \sinh \frac{a_k-a_{l-1} + 2 \epsilon_+}{2}.
\]  

(3.36)

\[
Z(\mathbf{v} = \mathbf{e}_{N-1} - \mathbf{e}_2, \zeta) < 0 = \sum_{l=2}^{N-1} \prod_{k \neq l} 2 \sinh \frac{a_l-a_k - m + \epsilon_+}{2} \sinh \frac{a_k-a_{l-1} + 2 \epsilon_+}{2}.
\]  

(3.37)

The expressions (3.36) and (3.37) match (3.33) and (3.34) specialized to \( \phi = a_i - \epsilon \) for \( \zeta > 0 \), and at \( \phi = a_i + \epsilon \) for \( \zeta < 0 \), both with \( i = 2, \cdots, N - 1 \), giving

\[
Z(\mathbf{v} = \mathbf{e}_{N-1} - \mathbf{e}_2, \zeta = 0) = \sum_{l=2}^{N-1} \prod_{k \neq l} 2 \sinh \frac{a_l-a_k - m + \epsilon_+}{2} \sinh \frac{a_k-a_{l-1} + 2 \epsilon_+}{2}.
\]  

(3.38)

The positive FI-parameter \( \zeta > 0 \) corresponds to JK parameter \( \eta = (1,1) \).23 In this region, the following sets of singular hyperplane arrangements contribute according to the JK residue prescription:

\[
\begin{align*}
\{ \phi_1 - a_i + \epsilon = 0 \} & \cap \{ \phi_2 - a_j + \epsilon = 0 \} & \text{for } i, j = 1, 2, \cdots, N, \tag{3.39} \\
\{ \phi_1 - a_i + \epsilon = 0 \} & \cap \{ \phi_2 - a_k \pm m + \epsilon = 0 \} & \text{for } i = 1, 2, \cdots, N, \tag{3.40} \\
\{ \phi_2 - a_i + \epsilon = 0 \} & \cap \{ \phi_1 - a_j \pm m + \epsilon = 0 \} & \text{for } i = 1, 2, \cdots, N. \tag{3.41}
\end{align*}
\]

The JK residues for (3.40) and (3.41) turn out to vanish, and the supersymmetric index is given by the sum of the residues associated with the singular hyperplane arrangements (3.39). The supersymmetric index for \( \zeta < 0 \) can be computed similarly. We get

\[
Z(\mathbf{v} = \mathbf{0}, \zeta) = \sum_{1 \leq i < j \leq N} \prod_{N_{l=i,j}}^{N} \prod_{k \neq i,j}^{N} \frac{\sinh \frac{a_l-a_k - m + \epsilon_+}{2} \sinh \frac{a_k-a_{l-1} + 2 \epsilon_+}{2}}{\sinh \frac{a_l-a_k}{2} \sinh \frac{a_k-a_{l-1} + 2 \epsilon_+}{2}}.
\]  

(3.42)

\[
Z(\mathbf{v} = \mathbf{0}, \zeta) = \sum_{1 \leq i < j \leq N} \prod_{N_{l=i,j}}^{N} \prod_{k \neq i,j}^{N} \frac{\sinh \frac{a_l-a_k - m + \epsilon_+}{2} \sinh \frac{a_k-a_{l-1} + 2 \epsilon_+}{2}}{\sinh \frac{a_l-a_k - 2 \epsilon_+}{2} \sinh \frac{a_k-a_{l-1} - 2 \epsilon_+}{2}}.
\]  

(3.43)

23See appendix 2.2 of [13] for our convention regarding the JK parameter \( \eta \).
The supersymmetric indices (3.42) and (3.43) agree with $Z^{\wedge V \times \wedge V}_{\text{mono}}(v = 0)$ obtained from the Moyal product. For several small values of $N$ we checked that $Z(\zeta > 0) = Z(\zeta < 0)$, i.e., there is no wall-crossing, so that

$$\langle T_{e_{N-1}+e_N-e_1-e_2}\rangle = \langle T^{\wedge V}\rangle \ast \langle T^{\wedge V}\rangle = \langle T^{\wedge V}\rangle \ast \langle T^{\wedge V}\rangle.$$  (3.44)

4 't Hooft operators in SO($N$) gauge theories

It is possible to compute the expectation values of 't Hooft operators of theories with a different gauge group. In this section we consider 't Hooft operators in $B$ or $D$-type gauge theories, namely SO($N$) gauge theories. In particular we focus on 4d $\mathcal{N} = 2$ SO($N$) gauge theory with $N - 2$ hypermultiplets in the vector representation and the 4d $\mathcal{N} = 2^*$ SO($N$) gauge theory.

4.1 $\mathcal{N} = 2$ SQCD

We start from 't Hooft operators in the 4d SO($N$) gauge theory with $N - 2$ hypermultiplets in the vector representation. The Langlands dual is different whether $N$ is even or odd. When $N = 2n$ the Langlands dual is SO($2n$), namely it is self-dual. When $N = 2n + 1$ the Langlands dual is USp($2n$). Then the minimal 't Hooft line operator is in the fundamental representation of SO($2n$) or USp($2n$). In both cases the expectation value on $S^1 \times \mathbb{R}^3$ takes the form

$$\langle T_V \rangle = \sum_{i=1}^{n} \left( e^{b_i} Z_i(a) + e^{-b_i} Z_i(a) \right),$$  (4.1)

where

$$Z_i(a) = \left( \frac{\prod_{f=1}^{N-2} 2 \sinh \frac{a_i - m_f}{2}}{\prod_{1 \leq j \neq i \leq n} 2 \sinh \frac{a_i + a_j + \epsilon}{2}} \right)^{\frac{1}{2}}$$  (4.2)

for the SO($2n$) gauge theory, and

$$Z_i(a) = \left( \frac{\prod_{f=1}^{N-2} 2 \sinh \frac{a_i - m_f}{2}}{2 \sinh \frac{a_i + \epsilon}{2} \prod_{1 \leq j \neq i \leq n} 2 \sinh \frac{a_i + a_j + \epsilon}{2}} \right)^{\frac{1}{2}}$$  (4.3)

for the SO($2n + 1$) gauge theory.
The simplest example of the Moyal product is the Moyal product between the expectation value of the minimal 't Hooft operators. The explicit computation gives

\[
\langle T_V \rangle * \langle T_V \rangle \quad \text{(4.4)}
\]

\[
= \sum_{1 \leq i < j \leq n} (e^{b_i+b_j} Z_i(a + \epsilon_+ e_j) Z_j(a - \epsilon_+ e_i) + e^{-b_i-b_j} Z_i(a - \epsilon_+ e_j) Z_j(a + \epsilon_+ e_i))
\]

\[
+ \sum_{1 \leq i \neq j \leq n} (e^{b_i-b_j} Z_i(a - \epsilon_+ e_j) Z_j(a - \epsilon_+ e_i) + e^{-b_i+b_j} Z_i(a + \epsilon_+ e_j) Z_j(a + \epsilon_+ e_i))
\]

\[
+ \sum_{i=1}^{n} (Z_i(a - \epsilon_+ e_i)^2 + Z_i(a + \epsilon_+ e_i)^2)
\]

\[
= \sum_{1 \leq i \leq n} (e^{2b_i} + e^{-2b_i}) Z_i(a + \epsilon_+ e_i) Z_i(a - \epsilon_+ e_i)
\]

\[
+ \sum_{1 \leq i < j \leq n} \sum_{s,t=\pm 1} e^{s(b_i+t) + t(b_j)} (Z_i(a + t\epsilon_+ e_j) Z_j(a - s\epsilon_+ e_i) + Z_i(a - t\epsilon_+ e_j) Z_j(a + s\epsilon_+ e_i))
\]

\[
+ \sum_{i=1}^{n} (Z_i(a - \epsilon_+ e_i)^2 + Z_i(a + \epsilon_+ e_i)^2).
\]

We have two types of the screening sector in (4.4). One is characterized by \( v = \pm e_i \pm e_j \) \((1 \leq i < j \leq n, \text{ signs uncorrelated})\)\(^{24}\) in the line second from the last in (4.4) and the other is the sector \( v = 0 \), which is given by the last line in (4.4). We now compare the monopole screening contributions in the Moyal product (4.4) with the supersymmetric indices of the SQMs that describe monopole screening.

\( v = \pm e_i \pm e_j \) \((i \neq j)\). We focus on the sector \( v = e_{n-1} + e_n \) since the other cases are related by Weyl reflections. For brane construction we focus on the realization of the gauge theory and 't Hooft operators using an O4−-plane discussed in section 2.2, although we could alternatively consider the realization using O6-planes discussed in section 2.3. The brane configuration for the sector \( v = e_{n-1} + e_n \) is shown in figure 14a. The corresponding

\(^{24}\)For \( N = 2n \) these correspond to all the coroots of SO(2n). For \( N = 2n + 1 \) they correspond to the short coroots of SO(2n + 1).
The supersymmetric index of the quiver theory is shown in figure 15a. The corresponding quiver diagram is depicted in figure 15b. The supersymmetric index of the quiver theory is

\[
Z(\mathbf{v} = e_{n-1} + e_n; \zeta) = \int d\phi_1 \frac{d\phi_2}{2\pi i} 2\pi i \prod_{i=n-1}^{n} \frac{2\sinh \epsilon_+}{2\sinh \frac{\phi_i - \phi_{i+1} + \epsilon_+}{2}} \prod_{i=n-1}^{n} \frac{1}{2\sinh \frac{\phi_i - \phi_{i+1} + \epsilon_+}{2}},
\]  

(4.5)

for the both signs of the FI parameter \(\zeta\).

For the second line of (4.4), the contribution \(Z_{\text{mono}}(\mathbf{v} = e_{n-1} + e_n; a)\) from the sector \(\mathbf{v} = e_{n-1} + e_n\) is determined by

\[
Z_{n-1}(a + \epsilon_+ e_n)Z_n(a - \epsilon_+ e_n - 1) = Z_{(n-1)n}(a)Z_{\text{mono}}(\mathbf{v} = e_{n-1} + e_n; a),
\]

(4.6)

where \(Z_{(n-1)n}(a)\) is the specialization to \(i = n - 1, j = n\) of

\[
Z_{ij}(a) = \left( \frac{\prod_{f=1}^{N-2} 2\sinh \frac{\pm a_i - m_f}{2} 2\sinh \frac{\pm a_j - m_f}{2} \prod_{k \neq i, j} 2\sinh \frac{\pm a_k - a_i + a_j + 2\epsilon_+}{2}}{2\sinh \frac{\pm a_i + \epsilon_+}{2} 2\sinh \frac{\pm a_j + \epsilon_+}{2} \prod_{1 \leq k \neq i, j \leq n} 2\sinh \frac{\pm a_k - a_i + a_j + 2\epsilon_+}{2}} \right)^{\frac{1}{2}},
\]

(4.7)

for \(N = 2n\), or

\[
Z_{ij}(a) = \left( \frac{\prod_{f=1}^{N-2} 2\sinh \frac{\pm a_i - m_f}{2} 2\sinh \frac{\pm a_j - m_f}{2} \prod_{k \neq i, j} 2\sinh \frac{\pm a_k - a_i + a_j + 2\epsilon_+}{2}}{2\sinh \frac{\pm a_i + \epsilon_+}{2} 2\sinh \frac{\pm a_j + \epsilon_+}{2} \prod_{1 \leq k \neq i, j \leq n} 2\sinh \frac{\pm a_k - a_i + a_j + 2\epsilon_+}{2}} \right)^{\frac{1}{2}}
\]

(4.8)

for \(N = 2n + 1\). Then from (4.6) we have

\[
Z_{\text{mono}}(\mathbf{v} = e_{n-1} + e_n; a) = \frac{1}{2\sinh \frac{a_{n-1} - a_n}{2} 2\sinh \frac{-a_{n-1} + a_n + 2\epsilon_+}{2}} + \frac{1}{2\sinh \frac{a_{n} - a_{n-1} - 2\epsilon_+}{2} 2\sinh \frac{-a_n + a_{n-1} + 2\epsilon_+}{2}},
\]

(4.9)

which reproduces (4.5).

\(\mathbf{v} = 0\). The brane configuration we use to read off the SQM for the sector \(\mathbf{v} = 0\) is shown in figure 15a. The corresponding quiver diagram is depicted in figure 15b. The supersymmetric index of the quiver theory is

\[
Z(\mathbf{v} = 0, \zeta) = \frac{1}{2} \int d\phi_1 \frac{d\phi_2}{2\pi i} 2\pi i 2\sinh(\pm \phi_1) \times \frac{(2\sinh \epsilon_+)^2 2\sinh(\pm \phi_1 + \epsilon_+)}{\prod_{i=1}^{n} 2\sinh \frac{\pm \phi_1 - m_f}{2} 2\sinh \frac{\pm \phi_1 + m_f}{2} \prod_{i=1}^{n} 2\sinh \frac{\pm \phi_1 + \epsilon_+}{2} 2\sinh \frac{\pm \phi_1 + \epsilon_+}{2}}.
\]

(4.10)
Figure 15.  (a): the brane configuration for the monopole screening contribution to the $v = 0$ sector in $T_V \cdot T_V$.  (b): the corresponding quiver diagram.

for $N = 2n$ and

$$Z(v = 0, \zeta) = \frac{1}{2} \oint_{\delta K(\zeta)} \frac{d\phi_1}{2\pi i} \frac{d\phi_2}{2\pi i} 2\sinh(\pm \phi_1)$$

$$\times \left( (2 \sinh \epsilon_+)^2 2 \sinh(\pm \phi_1 + \epsilon_+) \left( \prod_{i=1}^{N-2} 2 \sinh \frac{\pm \phi_i - m_i}{2} \right) \right)$$

$$\times 2 \sinh \frac{\pm \phi_1 + \epsilon_+}{2} \left( \prod_{i=1}^{n} 2 \sinh \frac{\pm \phi_i + \epsilon_+}{2} \right) 2 \sinh \frac{\pm \phi_1 + \phi_2 + \epsilon_+}{2}. \quad (4.11)$$

for $N = 2n + 1$.  The FI parameter $\zeta$ is associated to the $U(1)$ gauge node in figure 15b.  Namely for evaluating the integral (4.10) and (4.11) with the JK residue prescription, we choose the reference vector $\eta = (0, \zeta)$.  In order to use the constructive definition of the JK residue, we deform the reference vector as $\eta = (\delta, \zeta)$ with $|\delta| \ll |\zeta|$.  Then we find the relation

$$\langle T_V \rangle \ast \langle T_V \rangle_{v=0} = Z(v = 0, \zeta), \quad (4.12)$$

for general $N$, irrespective of the sign of $\zeta$.  This relation is indeed expected because the product of two identical operators does not depend on the ordering.

4.2 $\mathcal{N} = 2^*$ theory

We now consider the $\mathcal{N} = 2^*$ theory with gauge group $SO(N)$, i.e., the 4d $SO(N)$ gauge theory with a hypermultiplet of mass $m$ in the adjoint representation.  As in the SQCD case, the minimal 't Hooft line operator corresponds to the fundamental representation of $SO(2n)$ for $N = 2n$, and of $USp(2n)$ for $N = 2n + 1$.  In both cases the expectation value of the minimal 't Hooft operator $T_V$ takes the same form as (4.1), namely

$$\langle T_V \rangle = \sum_{i=1}^{n} \left( e^{h_i} Z_i(a) + e^{-h_i} Z_i(a) \right), \quad (4.13)$$

with

$$Z_i(a) = \left( \prod_{1 \leq j \neq i \leq n} 2 \sinh \frac{\pm a_i \pm a_j - m}{2} \right)^{\frac{1}{2}} \left( \prod_{1 \leq j \neq i \leq n} 2 \sinh \frac{\pm a_i \pm a_j + \epsilon_+}{2} \right)^{\frac{1}{2}}. \quad (4.14)$$
for the SO(2n) gauge theory and

\[
Z_i(a) = \left( \frac{2 \sinh \frac{\pm a_i - m}{2} \prod_{1 \leq j < i \leq n} 2 \sinh \frac{\pm a_i + a_j - m}{2} \prod_{1 \leq j \neq i \leq n} 2 \sinh \frac{\pm a_i + a_j + e_+}{2}}{2 \sinh \frac{\pm a_i + a_j}{2}} \right)^{\frac{1}{2}}
\]  \quad (4.15)

for the SO(2n + 1) gauge theory.

For gauge group SO(3) the \( N = 2^* \) theory trivially coincides with the SQCD with one flavor. For \( n = 1 \) indeed, (4.15) equals (4.3) with the identification \( m = m_{f_1} \).

For the 4d \( N = 2^* \) SO(N) gauge theory we also consider the `t Hooft operator with magnetic charge \( B = e_{n-1} + e_n \). This corresponds to the rank-2 anti-symmetric representation \( \Lambda^2 V \) of the Langlands dual group, which is SO(2n) for gauge group SO(2n) and USp(2n) for gauge group SO(2n + 1). The brane realization of the operator is similar to the one in figure 4b; we remove D6-branes and replace O4 by O6\( ^+ \). The expectation value of this operator, denoted as \( T_{\Lambda^2 V} \), takes the form

\[
\langle T_{\Lambda^2 V} \rangle = \sum_{1 \leq i < j \leq n} \left( e^{b_i + b_j} + e^{-b_i - b_j} \right) Z_{ij}(a) + \sum_{1 \leq i < j \leq n} \left( e^{b_i - b_j} + e^{-b_i + b_j} \right) Z_{ij}'(a) + Z_{\text{mon}}(a).
\]  \quad (4.16)

The one-loop determinants are given as

\[
Z_{ij}(a) = \left( \frac{2 \sinh \frac{\pm (a_i + a_j) - m + \epsilon_+}{2} \prod_{k \neq i, j} 2 \sinh \frac{\pm a_i + a_k - m}{2} 2 \sinh \frac{\pm a_j + a_k - m}{2} \prod_{k \neq i, j} 2 \sinh \frac{\pm a_i + a_k + \epsilon_+}{2} 2 \sinh \frac{\pm a_j + a_k + \epsilon_+}{2}}{2 \sinh \frac{\pm (a_i + a_j)}{2}} 2 \sinh \frac{\pm (a_i + a_j) + 2 \epsilon_+}{2} \prod_{k \neq i, j} 2 \sinh \frac{\pm a_i + a_k + \epsilon_+}{2} 2 \sinh \frac{\pm a_j + a_k + \epsilon_+}{2} \right)^{\frac{1}{2}},
\]  \quad (4.17)

\[
Z_{ij}'(a) = \left( \frac{2 \sinh \frac{\pm (a_i - a_j) - m + \epsilon_+}{2} \prod_{k \neq i, j} 2 \sinh \frac{\pm a_i + a_k - m}{2} 2 \sinh \frac{\pm a_j + a_k - m}{2} \prod_{k \neq i, j} 2 \sinh \frac{\pm a_i + a_k + \epsilon_+}{2} 2 \sinh \frac{\pm a_j + a_k + \epsilon_+}{2}}{2 \sinh \frac{\pm (a_i - a_j)}{2}} 2 \sinh \frac{\pm (a_i - a_j) + 2 \epsilon_+}{2} \prod_{k \neq i, j} 2 \sinh \frac{\pm a_i + a_k + \epsilon_+}{2} 2 \sinh \frac{\pm a_j + a_k + \epsilon_+}{2} \right)^{\frac{1}{2}},
\]  \quad (4.18)

for \( N = 2n \), and

\[
Z_{ij}(a) = \left( \frac{2 \sinh \frac{\pm (a_i + a_j) - m + \epsilon_+}{2} \prod_{k \neq i, j} 2 \sinh \frac{\pm a_i + a_k - m}{2} 2 \sinh \frac{\pm a_j + a_k - m}{2} \prod_{k \neq i, j} 2 \sinh \frac{\pm a_i + a_k + \epsilon_+}{2} 2 \sinh \frac{\pm a_j + a_k + \epsilon_+}{2}}{2 \sinh \frac{\pm (a_i + a_j)}{2}} 2 \sinh \frac{\pm (a_i + a_j) + 2 \epsilon_+}{2} \prod_{k \neq i, j} 2 \sinh \frac{\pm a_i + a_k + \epsilon_+}{2} 2 \sinh \frac{\pm a_j + a_k + \epsilon_+}{2} \right)^{\frac{1}{2}},
\]  \quad (4.19)

\[
Z_{ij}'(a) = \left( \frac{2 \sinh \frac{\pm (a_i - a_j) - m + \epsilon_+}{2} \prod_{k \neq i, j} 2 \sinh \frac{\pm a_i + a_k - m}{2} 2 \sinh \frac{\pm a_j + a_k - m}{2} \prod_{k \neq i, j} 2 \sinh \frac{\pm a_i + a_k + \epsilon_+}{2} 2 \sinh \frac{\pm a_j + a_k + \epsilon_+}{2}}{2 \sinh \frac{\pm (a_i - a_j)}{2}} 2 \sinh \frac{\pm (a_i - a_j) + 2 \epsilon_+}{2} \prod_{k \neq i, j} 2 \sinh \frac{\pm a_i + a_k + \epsilon_+}{2} 2 \sinh \frac{\pm a_j + a_k + \epsilon_+}{2} \right)^{\frac{1}{2}},
\]  \quad (4.20)
for \( N = 2n + 1 \). The last term \( Z_{\text{mono}}(a) \) in (4.16) is the monopole screening contribution corresponding to the zero weights in the rank-2 anti-symmetric representation.\(^{25}\) Unlike \( T_V \), the expectation value of \( T_{\wedge^2 V} \) contains a monopole screening contribution which will be determined by the supersymmetric index of the corresponding SQM.

### 4.2.1 \( \wedge^2 V \)

We wish to determine the \( v = 0 \) term \( Z_{\text{mono}}(a) \) in (4.16), for the \( \mathcal{N} = 2^* \) theory using brane construction and an SQM. The brane configuration for the \( v = 0 \) sector is shown in figure 16a, and the corresponding SQM quiver in 16b. The supersymmetric index is given by the contour integral

\[
Z_{\wedge^2 V}(v = 0) = -\frac{1}{2} \oint_{JK(q)} \frac{d\phi}{2\pi i} \frac{2 \sinh(\pm \phi)(2 \sinh \epsilon_+)}{2 \sinh(\pm \phi + \frac{\pm m - \epsilon_+}{2})} \times \frac{2 \sinh(\pm \phi + \pm \alpha_i + m)}{2 \sinh(\pm \phi + \pm \alpha_i + \epsilon_+)} \frac{\prod_{i=1}^n 2 \sinh(\pm \phi + \pm \alpha_i + \frac{m}{2})}{\prod_{i=1}^n 2 \sinh(\pm \phi + \pm \alpha_i + \frac{\epsilon_+}{2})}
\]

(4.21)

for \( N = 2n \) and

\[
Z_{\wedge^2 V}(v = 0) = -\frac{1}{2} \oint_{JK(q)} \frac{d\phi}{2\pi i} \frac{2 \sinh(\pm \phi)(2 \sinh \epsilon_+)}{2 \sinh(\pm \phi + \frac{\pm m - \epsilon_+}{2})} \times \frac{2 \sinh(\pm \phi + \pm m)}{2 \sinh(\pm \phi + \pm \alpha_i + \frac{m}{2})} \frac{\prod_{i=1}^n 2 \sinh(\pm \phi + \pm \alpha_i + m)}{\prod_{i=1}^n 2 \sinh(\pm \phi + \pm \alpha_i + \epsilon_+)} \frac{\prod_{i=1}^n 2 \sinh(\pm \phi + \pm \alpha_i + \frac{m}{2})}{\prod_{i=1}^n 2 \sinh(\pm \phi + \pm \alpha_i + \frac{\epsilon_+}{2})}
\]

(4.22)

for \( N = 2n + 1 \).

\(^{25}\)The rank-2 anti-symmetric representation of SO(2n) is the adjoint representation of SO(2n). The rank-2 anti-symmetric representation of USp(2n) for \( n \geq 2 \) is reducible. After subtracting a singlet, the remaining part has dimension \( 2n^2 - n - 1 \). Both the adjoint representation of SO(2n) and the irreducible representation of USp(2n) with dimension \( 2n^2 - n - 1 \) are quasi-minuscule; all non-zero weights \( \{\pm \epsilon_i \pm \epsilon_j | i < j \} \) lie in the same orbit under the Weyl group action.
Then $Z_{\wedge^2 V}(v = 0)$ is given by the sum of the residues of the appropriate poles. For example when the JK parameter is positive, $\eta > 0$, the relevant poles are at $\phi = -\frac{m + \epsilon_+}{2}, \frac{m + \epsilon_+}{2} + \pi i, -\langle \Delta_a + \epsilon_+ \rangle$ for $N = 2n$. For $N = 2n + 1$, in addition to the same poles, we should also include the pole at $\phi = -\epsilon_+$. We propose that we need to include the overall minus signs in (4.21) and (4.22) by hand. To obtain the monopole screening contribution from $Z_{\wedge^2 V}(v = 0)$ we need to remove the extra term from $Z_{\wedge^2 V}(v = 0)$ as discussed in section 2.5. For $N = 2n$ we believe that the extra term is given by

$$Z_{\text{extra}} = \frac{\cosh \epsilon_+}{2 \cosh \frac{m \pm \epsilon_+}{2}},$$

(4.23)

which we checked explicitly for $n = 2, 3, 4, 5$. For $N = 2n + 1$ we believe that the extra term is given by

$$Z_{\text{extra}} = -\frac{\cosh \epsilon_+}{2 \cosh \frac{m \pm \epsilon_+}{2}},$$

(4.24)

which we checked explicitly for $n = 2, 3, 4, 5$. According to the extra term prescription in section 2.5, $Z_{\text{mono}}(a)$ in (4.16) is given by

$$Z_{\text{mono}}(a) = Z_{\wedge^2 V}(v = 0) - Z_{\text{extra}}.$$

(4.25)

We will check the necessity of the signs as well as the extra term prescription by comparing the vevs $T_{\wedge^2 V}$ for $N = 4$ (below) $N = 5$ (in section 5), and $N = 6$ (below) with the vevs of the 't Hooft operators corresponding to the adjoint representation for gauge groups $U(2) \times U(2), \text{USp}(4)$, and $U(4)$, respectively.

**SO(4) versus SU(2) × SU(2).** For $N = 4$, we note that $so(4) = su(2) \oplus su(2)$, and that $\wedge^2 V$ of $so(4)$ is the adjoint representation. This motivates us to compare $\langle T_{\wedge^2 V} \rangle \equiv \langle T_{\wedge^2 V}^{SO(4)} \rangle$ for SO(4) with (two copies of) the vev $\langle T_{\text{adj}}^{SU(2)} \rangle$ of the 't Hooft operator which is S-dual to the adjoint Wilson operator. The result of Secition 3.2.1 implies

$$\langle T_{\text{adj}}^{SU(2)} \rangle = (e^b + e^{-b}) \left( \frac{2 \sinh \frac{a + \epsilon_+ - m}{2}}{2 \sinh \frac{a + \epsilon_+ + m}{2} \sinh \frac{a}{2}} \right)^{1/2} + Z_{\text{mono}}^{SU(2)}$$

(4.28)

with

$$Z_{\text{mono}}^{SU(2)} = \frac{2 \sinh \frac{a - \epsilon_+ + m}{2}}{2 \sinh \frac{a - \epsilon_+ - m}{2} \sinh \frac{a}{2}} + \frac{2 \sinh \frac{-a - \epsilon_+ + m}{2}}{2 \sinh \frac{-a - \epsilon_+ - m}{2} \sinh \frac{-a}{2}} - 1.$$  

(4.29)

### Footnote

26The vev of the adjoint 't Hooft operator in $N = 2^* U(N)$ and $N = 2^* SU(N)$ should be related as

$$\langle T_{\text{adj}}^{SU(N)} \rangle = \langle T_{\text{adj}}^{U(N)} \rangle - 1,$$

(4.26)

where the traceless condition is imposed for SU(N). We subtract one because of the difference between the number of zero weights of the adjoint representation of SU(N) and that of the adjoint representation of U(N). In particular for $N = 2$, the relation is

$$\langle T_{\text{adj}}^{SU(2)} \rangle = \langle T_{\text{adj}}^{U(2)} \rangle \bigg|_{a_1 - a_2 \rightarrow a} - 1.$$  

(4.27)
It can be checked that
\[ Z_{\text{SO}(4)}^{\text{SO}(4)}(v = 0) - Z_{\text{mono}}^{\text{SU}(2)}|_{a \to a_1 + a_2, b \to b_1 + b_2} - Z_{\text{mono}}^{\text{SU}(2)}|_{a \to a_1, b \to b_1} = \frac{\cosh \epsilon_+}{2 \cosh \frac{m \epsilon_+}{2}}, \] (4.30)
where \( a_{1,2} \) and \( b_{1,2} \) are the parameters of the SO(4) theory. Indeed we can see that (4.30) is precisely equal to (4.23) and hence we have the equality
\[ Z_{\text{mono}}^{\text{SO}(4)}(a) = Z_{\text{mono}}^{\text{SU}(2)}|_{a \to a_1 + a_2, b \to b_1 + b_2} + Z_{\text{mono}}^{\text{SU}(2)}|_{a \to a_1, b \to b_1}, \] (4.31)
where \( Z_{\text{mono}}^{\text{SO}(4)}(a) \) is given by (4.25) with \( N = 4 \). This further implies
\[ \langle T_{\text{SO}(4)}^{\text{SO}(4)} \rangle = \langle T_{\text{adj}}^{\text{SU}(2)} \rangle |_{a \to a_1, b \to b_1} + \langle T_{\text{adj}}^{\text{SU}(2)} \rangle |_{a \to a_1 - a_2, b \to b_1 - b_2}, \] (4.32)
We interpret the three brackets as the vevs of the adjoint 't Hooft operator in the gauge theories with gauge groups SO(4), SU(2), and SU(2) from left to right.

**SO(6) versus SU(4).** For \( N = 6 \), the relation \( so(6) = su(4) \) motivates us to compare \( \langle T_{\Lam^2 V}^{\text{SO}(6)} \rangle \equiv \langle T_{\Lam^2 V}^{\text{SU}(6)} \rangle \) for SO(6) with the vev of the 't Hooft operator \( T_{\text{adj}}^{\text{SU}(4)} \) corresponding to the adjoint representation of SU(4). Since \( \langle T_{\text{adj}}^{\text{SU}(4)} \rangle = \langle T_{\text{V}}^{\text{U}(4)} \rangle \) this implies
\[ \langle T_{\text{adj}}^{\text{SU}(4)} \rangle = \frac{1}{4} \sum_{1 \leq i < j \leq 4} (e^{b_i - b_j} + e^{b_j - b_i}) Z_i(a - \epsilon_i e_j) Z_j(a - \epsilon_j e_i) + Z_{\text{mono}}^{\text{SU}(4)}, \] (4.33)
where
\[ Z_{\text{mono}}^{\text{SU}(4)} = \prod_{1 \leq i < j \leq 4} \left( 2 \sinh \frac{a_i - a_j - m}{2} \sinh \frac{a_i + a_j + m}{2} \right)^{\frac{1}{2}}, \] (4.34)
The vev \( \langle T_{\text{adj}}^{\text{SU}(4)} \rangle \) depends only on the differences \( a_i - a_j \) and \( b_i - b_j \). Note that the Dynkin diagram for SO(6) is identical to that for SU(4). From the identifications of the nodes, which correspond to simple roots, we identify the parameters \((a_1 - a_2, a_2 - a_3, a_3 - a_4, a_4 - a_1)\) of SU(4) with \((a_2 - a_3, a_1 - a_2, a_2 + a_3)\) of SO(6). We make similar identifications for \( b_i \). We find that
\[ Z_{\text{SO}(4)}^{\text{SO}(6)}(v = 0) - Z_{\text{mono}}^{\text{SU}(4)}|_{(a_1 - a_2, a_2 - a_3, a_3 - a_4) \to (a_2 - a_3, a_1 - a_2, a_2 + a_3)} = \frac{\cosh \epsilon_+}{2 \cosh \frac{m \epsilon_+}{2}}, \] (4.36)
where the right hand side is independent of \( a_i \) and \( b_i \). Again (4.36) precisely agrees with (4.23) and hence we have the equality
\[ Z_{\text{mono}}^{\text{SO}(6)}(a) = Z_{\text{mono}}^{\text{SU}(4)}|_{(a_1 - a_2, a_2 - a_3, a_3 - a_4) \to (a_2 - a_3, a_1 - a_2, a_2 + a_3)}, \] (4.37)
where \( Z_{\text{mono}}^{\text{SO}(6)}(a) \) is given by (4.25) with \( N = 6 \). Namely, we have
\[ \langle T_{\text{adj}}^{\text{SU}(4)} \rangle = \langle T_{\text{adj}}^{\text{SU}(4)} \rangle |_{(a_1 - a_2, a_2 - a_3, a_3 - a_4) \to (a_2 - a_3, a_1 - a_2, a_2 + a_3)}, \] (4.38)
The equality is in accord with the discussion in section 2.5.

\(^{27}\)Note that \( \langle T_{\text{adj}}^{\text{U}(4)} \rangle \) is related to \( \langle T_{\text{adj}}^{\text{SU}(4)} \rangle \) by (4.26).
$D_4 \otimes O_6^+ + D_4$.

\[ (a) \]

Figure 17. (a): the brane configuration for the monopole screening contribution to the $v = e_{n-1} + e_n$ sector in $T_V \cdot T_V$. (b): the corresponding quiver diagram.

### 4.2.2 $V \times V$

The Moyal product between the expectation value of the minimal 't Hooft operators is again given by (4.4) with $Z_i$ given by (4.14) or (4.15). We have two types of the screening sector.

$v = \pm e_i \pm e_j \ (i \neq j)$. The terms in the line second from the last in (4.4) with the one-loop determinant (4.14) and (4.15) corresponds to the monopole screening sectors $v = \pm e_i \pm e_j \ (i \neq j)$. We only focus on $v = e_{n-1} + e_n$ as the other choices are related by Weyl reflections. The monopole screening contribution $Z_{\text{mono}}(v = e_{n-1} + e_n; a)$ is given by

\[
Z_{\text{mono}}(v = e_{n-1} + e_n; a) = 2 \sinh \frac{a - a_{n-1} - m + \epsilon + 2 \epsilon}{2} \sinh \frac{-a_{n-1} - a - m - \epsilon + 2 \epsilon}{2} + \frac{2 \sinh \frac{a - a_{n-1} - m + \epsilon + 2 \epsilon}{2} \sinh \frac{-a_{n-1} - a - m - \epsilon + 2 \epsilon}{2}}{2 \sinh \frac{a - a_{n-1} + \epsilon + 2 \epsilon}{2} \sinh \frac{-a_{n-1} - a - m - \epsilon + 2 \epsilon}{2}}.
\]

(4.40)

The brane configuration for this sector is shown in figure 17a, and the SQM quiver in figure 17b. This is the special case $N = 2$ of figure 12c. The supersymmetric index can be obtained from the result (3.26) or (3.27), and it is identical to the right hand side of (4.40), as expected.

$v = 0$. The last line of (4.4) is the contribution from the monopole screening sector $v = 0$. The brane configuration for this sector is shown in figure 18a, and the SQM quiver
in figure 18b. The supersymmetric index is given by the contour integral

\[
Z(v = 0, \zeta) = \frac{1}{2} \oint_{JK(\zeta)} \frac{d\phi_1 d\phi_2}{2\pi i} \frac{2\sinh(\pm \phi_1)(2\sinh \epsilon_+)^2 2\sinh(\pm \phi_1 + \epsilon_+)}{2\sinh(\pm \phi_1 + \frac{\pm m - \epsilon_+}{2})(2\sinh(\frac{m + \epsilon_+}{2}))^2} \\
\times \left(\frac{\prod_{i=1}^n 2\sinh \frac{\pm \phi_1 - \alpha_i + m}{2}}{\prod_{i=1}^n 2\sinh \frac{\pm \phi_1 - \alpha_i + \epsilon_+}{2}}\right) 2\sinh \frac{\pm \phi_1 - \phi_2 + m}{2},
\]

(4.41)

for \( N = 2n \) and

\[
Z(v = 0, \zeta) = \frac{1}{2} \oint_{JK(\zeta)} \frac{d\phi_1 d\phi_2}{2\pi i} \frac{2\sinh(\pm \phi_1)(2\sinh \epsilon_+)^2 2\sinh(\pm \phi_1 + \epsilon_+)}{2\sinh(\pm \phi_1 + \frac{\pm m - \epsilon_+}{2})(2\sinh(\frac{m + \epsilon_+}{2}))^2} \\
\times \frac{2\sinh \frac{\pm \phi_1 + m}{2} \left(\prod_{i=1}^n 2\sinh \frac{\pm \phi_1 + \alpha_i + m}{2}\right) 2\sinh \frac{\pm \phi_1 + \phi_2 + m}{2}}{2\sinh \frac{\pm \phi_1 + \epsilon_+}{2} \left(\prod_{i=1}^n 2\sinh \frac{\pm \phi_1 + \alpha_i + \epsilon_+}{2}\right) 2\sinh \frac{\pm \phi_1 + \phi_2 + \epsilon_+}{2}},
\]

(4.42)

for \( N = 2n + 1 \). The FI parameter \( \zeta \) is associated to the U(1) gauge node in figure 18, and we evaluate the integral (4.41) and (4.42) with the JK residue prescription using the JK parameter \( \eta = (0, \zeta) \). More precisely, to use the constructive definition of the JK residue, we deform the JK parameter to \( \eta = (\delta, \zeta) \) with \( |\delta| \ll |\zeta| \). We checked that \( \langle T_V \rangle \star \langle T_V \rangle \big|_{v=0} = Z(\zeta) \) for \( N = 4, 5, \ldots, 11 \) and \( \zeta > 0 \), as expected.

5 't Hooft operators in USp(2n) gauge theories

In this section we consider the expectation values of 't Hooft operators in USp(2n) gauge theories. In particular we focus on the 4d \( \mathcal{N} = 2 \) USp(2n) gauge theory with \( 2n + 2 \) flavors and also the 4d \( \mathcal{N} = 2^* \) USp(2n) gauge theory.

5.1 \( \mathcal{N} = 2 \) SQCD

In this subsection we consider the USp(2n) gauge theory with \( 2n + 2 \) hypermultiplets in the fundamental representation. The Langlands dual of USp(2n) is SO(2n + 1). The magnetic charge of the minimal 't Hooft operator \( T_V \) corresponds to the vector (fundamental)
representation $V$ of $\text{SO}(2n + 1)$. Unlike in $\text{U}(N)$ and $\text{SO}(N)$ gauge theories, in a $\text{USp}(2n)$ theory even the minimal ’t Hooft operator exhibits monopole screening. Its expectation value on $S^1 \times \mathbb{R}^3$ takes the form

$$
\langle T_V \rangle = \sum_{i=1}^{n} \left( e^{a_i} + e^{-a_i} \right) Z_i(a) + Z_{\text{mono}}(a),
$$

(5.1)

where

$$
Z_i(a) = \left( \frac{\prod_{f=1}^{2n+2} 2 \sinh \frac{\pm a_i - m_f}{2}}{2 \sinh(\pm a_i)2 \sinh(\pm a_i + \epsilon_+) \prod_{1 \leq j \neq i \leq n} 2 \sinh \frac{\pm a_j \pm a_i + \epsilon_+}{2}} \right)^{\frac{1}{2}},
$$

(5.2)

and $Z_{\text{mono}}(a)$ is the contribution from the monopole screening sector specified by the zero weight $v = 0$ in $V$.

We will determine $Z_{\text{mono}}(a)$ using an SQM in section 5.1.1. We will study the product of two copies of $T_V$ in section 5.1.2 using the Moyal product and SQMs.

### 5.1.1 $V$

Here we compute $Z_{\text{mono}}(a)$ in (5.1). The brane configuration for monopole screening is shown in figure 19a, and the corresponding SQM quiver in figure 19b. The non-connected group $O(1) \simeq \mathbb{Z}_2$ consists of two connected components, $O(1)_+ = \{1\}$ and $O(1)_- = \{-1\}$. Since these are discrete the supersymmetric index involves no integral. By averaging the contribution

$$
Z_{V_+}(v = 0) = \frac{\prod_{f=1}^{2n+2} 2 \sinh \frac{m_f}{2}}{\prod_{i=1}^{n} 2 \sinh \frac{\pm a_i + \epsilon_+}{2}},
$$

(5.3)

from $O(1)_+$ and the contribution

$$
Z_{V_-}(v = 0) = \frac{\prod_{f=1}^{2n+2} 2 \cosh \frac{m_f}{2}}{\prod_{i=1}^{n} 2 \cosh \frac{\pm a_i + \epsilon_+}{2}}.
$$

(5.4)
The supersymmetric index giving the monopole screening contribution is (4.5).

The brane configuration is the one given in figure 14a, where \( v = e_i \pm e_j \). We can also read off \( Z_{\text{mono}}(v = e_{n-1} + e_n; a) \) from the Moyal product (5.6) by writing

\[
Z_{n-1}(a + \epsilon_+ e_{n})Z_{n}(a - \epsilon_+ e_{n-1}) + Z_n(a + \epsilon_+ e_{n-1})Z_{n-1}(a - \epsilon_+ e_{n}) = Z_{(n-1)n}(a)Z_{\text{mono}}(v = e_{n-1} + e_n; a),
\]

in (5.5) with \( n = 1 \) has an expression different from those which appear in [9, 12, 14], but is in fact equal to them. The specialization to \( \epsilon_+ = 0 \) of (5.5) with \( n = 1 \), involving two terms each containing sinh only or cosh only, was obtained in appendix E of [9], where the correspondence between line operators and the \( \text{SL}(2, \mathbb{C}) \) holonomies on the four-punctured sphere was studied.

5.1.2 \( V \times V \)

Next we turn to the product of two copies of \( T_V \). The Moyal product is given by

\[
\langle T_V \rangle \star \langle T_V \rangle = \sum_{1 \leq i,j \leq n} \left( e^{b_{ij}} Z_i(a + \epsilon_+ e_j)Z_j(a - \epsilon_+ e_i) + e^{-b_{ij}} Z_i(a - \epsilon_+ e_j)Z_j(a + \epsilon_+ e_i) \right)
\]

\[
+ \sum_{1 \leq i \neq j \leq n} \left( e^{b_{ij}} Z_i(a - \epsilon_+ e_j)Z_j(a - \epsilon_+ e_i) + e^{-b_{ij}} Z_i(a + \epsilon_+ e_j)Z_j(a + \epsilon_+ e_i) \right)
\]

\[
+ \sum_{i=1}^n \left( e^{b_i} Z_i(a)^2 + Z_i(a + \epsilon_+ e_i)^2 \right) + Z_{\text{mono}}(a)^2.
\]

By the Weyl group action reviewed in appendices A.3 and A.4, the monopole screening contributions are classified into three types: \( v = \pm e_i \pm e_j \) for \( 1 \leq i < j \leq n \), \( v = \pm e_i \) for \( i = 1, \ldots, n \) and \( v = 0 \). We will study them one by one.

\( v = \pm e_i \pm e_j \) (\( i \neq j \)). We focus on the sector \( v = e_{n-1} + e_n \) since the other cases are related by Weyl reflections. The brane configuration is the one given in figure 14a, where the O4-plane is taken to be an O4\( ^\perp \)-plane. The SQM is given by the quiver in figure 14b. The supersymmetry index giving the monopole screening contribution to \( V \) is the same as the adjoint representation of the Langlands dual group \( \text{SO}(3) \).

In this case there is no extra term, and hence \( Z_{\text{mono}}(a) \) in (5.1) is given by (5.5).
**Figure 20.** (a): the brane configuration for the monopole screening sector $v = e_N$ of $T_V \cdot T_V$. (b): the corresponding SQM quiver diagram.

where $Z_{(n-1)n}(a)$ is the specialization of

$$Z_{ij}(a) = \left( \frac{\prod_{f=1}^{N_+} 2 \sinh \frac{\pm a_i - m_f}{2} 2 \sinh \frac{\pm a_j - m_f}{2}}{2 \sinh \frac{\pm (a_i + a_j) + 2\epsilon_+}{2} \prod_{1 \leq k \leq n} 2 \sinh \frac{\pm a_k + \epsilon_+}{2} 2 \sinh \frac{\pm a_k - \epsilon_+}{2}} \right) \times \frac{1}{2 \sinh(\pm a_i) 2 \sinh(\pm a_j) 2 \sinh(\pm a_i + \epsilon_+) 2 \sinh(\pm a_j + \epsilon_+)} \right)^{\frac{1}{2}}$$

(5.8)

The right hand side is the supersymmetric index (4.5) of the SQM specified by the quiver in figure 14b, as expected.

$v = \pm e_i$. The brane configuration and the quiver diagram for the SQM which describe monopole screening for the $v = \pm e_i$ sector are depicted in figure 20. We again use the $\mathcal{N} = (0, 4)$ notation. The supersymmetric index consists of contributions from two sectors, $O(1)+U(1)$ and $O(1)-U(1)$. The contribution from the $O(1)+U(1)$ sector is given by

$$Z+(v = \pm e_i, \zeta) = \int_{JK(\zeta)} \frac{d\phi}{2\pi i} \frac{2 \sinh(\epsilon_+) \prod_{j=1}^{2n+2} 2 \sinh \frac{m_j}{2}}{\prod_{1 \leq j \neq i \leq n} 2 \sinh \frac{\pm a_j + \epsilon_+}{2}}$$

(5.10)

On the other hand, the contribution from the $O(1)-U(1)$ sector is given by

$$Z-(v = \pm e_i, \zeta) = \int_{JK(\zeta)} \frac{d\phi}{2\pi i} \frac{2 \sinh(\epsilon_+) \prod_{j=1}^{2n+2} \cosh \frac{m_j}{2}}{\prod_{1 \leq j \neq i \leq n} \cosh \frac{\pm a_j + \epsilon_+}{2}}$$

(5.11)
Note that for the evaluation of the integral (5.11), one needs to include the pole \( \phi = -\epsilon_+ + i\pi \) for \( \zeta > 0 \) and \( \phi = \epsilon_+ + i\pi \) for \( \zeta < 0 \). The supersymmetric index for the \( v = \pm \epsilon_i \) sector is the average of the two contributions

\[
Z(v = \pm \epsilon_i, \zeta) = \frac{1}{2} (Z_+(v = \pm \epsilon_i, \zeta) + Z_-(v = \pm \epsilon_i, \zeta)).
\]  

(5.12)

The evaluation of the JK residue for the supersymmetric index gives the relation

\[
Z(v = \pm \epsilon_i, \zeta) = Z_{\text{mono}}(a - \epsilon_+ e_i) + Z_{\text{mono}}(a + \epsilon_+ e_i)
\]  

(5.13)

for \( \zeta > 0 \) and \( \zeta < 0 \). The right hand side of (5.13) appears in the third line of (5.6).

\( v = 0 \). The brane configuration for the \( v = 0 \) sector and the corresponding quiver diagram of the SQM are depicted in figures 21a and 21b, respectively. The supersymmetric index again consists of two contributions, for \( O(2)_+ - U(1) \) and \( O(2)_- - U(1) \). The contribution from the \( O(2)_+ - U(1) \) sector is given by

\[
Z_+(v = 0, \zeta) = \oint \frac{d\phi_1}{2\pi i} \frac{d\phi_2}{2\pi i} \frac{(2\sinh(\epsilon_+))^2 \prod_{j=1}^{2n+2} 2 \sinh \frac{\phi_1 - m_j}{2} \prod_{i=1}^{n} 2 \sinh \frac{\phi_1 \pm a_i + \epsilon_+}{2}}{2 \sinh(\pm \phi_2 + \epsilon_+).}
\]  

(5.14)

The contribution from the \( O(2)_- - U(1) \) sector is

\[
Z_-(v = 0, \zeta) = \oint \frac{d\phi_2}{2\pi i} \frac{2 \cos(\epsilon_+) 2 \sinh(\epsilon_+) \prod_{j=1}^{2n+2} 2 \sinh(m_j)}{2 \sinh(\pm \phi_2 + \epsilon_+) \prod_{i=1}^{n} 2 \sinh(\pm a_i + \epsilon_+)}
\]  

(5.15)

The supersymmetric index is then given by

\[
Z(v = 0, \zeta) = \frac{1}{2} (Z_+(v = 0, \zeta) + Z_-(v = 0, \zeta)).
\]  

(5.16)

Computing the integral (5.16) using the JK residue prescription, and comparing it with (5.2)–(5.5), we obtain the relation, for \( n = 1, 2 \),

\[
Z(v = 0, \zeta) = \sum_{i=1}^{n} \left( Z_i(a - \epsilon_+ e_i)^2 + Z_i(a + \epsilon_+ e_i)^2 \right) + Z_{\text{mono}}(a)^2
\]  

(5.17)
for the both signs of $\zeta$. In particular $\frac{1}{4}Z_{\text{mono}^+}^2$ and $\frac{1}{4}Z_{\text{mono}^-}^2$ come from the residues in $\frac{1}{2}Z_+(v = 0, \zeta)$ and $\frac{1}{2}Z_{\text{mono}^+}Z_{\text{mono}^-}$ is equal to $\frac{1}{2}Z_-(v = 0, \zeta)$. We conjecture that (5.17) holds for general $n$, for the both signs of $\zeta$.

### 5.2 $\mathcal{N} = 2^*$ theory

We now switch to the $\mathcal{N} = 2^*$ USp(2n) gauge theory, which is the $\mathcal{N} = 2$ USp(2n) gauge theory with a hypermultiplet in the adjoint representation. The expectation value of the minimal 't Hooft operator in the $\mathcal{N} = 2^*$ theory takes the same form as (5.1), namely

$$\langle T_V \rangle = \sum_{i=1}^{n} \left( e^{b_i} + e^{-b_i} \right) Z_i(a) + Z_{\text{mono}}(a),$$

(5.18)

but the functions $Z_i(a)$ and $Z_{\text{mono}}(a)$ are different. The contribution $Z_i(a)$ is determined by the general formulas (B.3) and (B.4) for the one-loop determinants as

$$Z_i(a) = \left( \frac{2 \sinh \frac{2a_i - m + \epsilon_+}{2} \prod_{1 \leq j \neq i \leq n} \sinh \frac{\pm a_i \pm a_j - m}{2}}{2 \sinh(\pm a_i) \sinh(\pm a_j + \epsilon_+) \prod_{1 \leq j \neq i \leq n} \sinh \frac{\pm a_i \pm a_j + \epsilon_+}{2} \right)^{\frac{1}{2}}.$$  

(5.19)

We will compute the monopole screening contribution $Z_{\text{mono}}(a)$ from the supersymmetric index of an SQM in section 5.2.1. For $m = \epsilon_+ = 0$ we expect from S-duality that $\langle T_V \rangle$ becomes equal to the vev of the Wilson operator in representation $V$ of the $\mathcal{N} = 4$ SO(2n + 1) gauge theory. This vev is simply the character of the representation [9]. Thus we expect the equation

$$\langle T_V \rangle = \sum_{i=1}^{n} \left( e^{b_i} + e^{-b_i} \right) + 1$$

(5.20)

to hold. In section 5.2.1 we will choose by hand the overall sign of the contour integral for $Z_{\text{mono}}(a)$ so that (5.20) holds.

We also consider the vev of the 't Hooft operator $T_{\lambda^2 V}$, which takes the form

$$\langle T_{\lambda^2 V} \rangle = \sum_{1 \leq i < j \leq n} \left( e^{b_i + b_j} + e^{-b_i - b_j} \right) Z_{ij}(a) + \sum_{1 \leq i < j \leq n} \left( e^{b_i - b_j} + e^{-b_i + b_j} \right) Z'_{ij}(a) + \sum_{i=1}^{n} \left( e^{b_i} + e^{-b_i} \right) Z_i(a) Z'_{\text{mono},i}(a) + Z''_{\text{mono}}(a).$$

(5.21)

The one-loop determinants are given by the general formulas (B.3) and (B.4) as

$$Z_{ij}(a) = \left( \frac{2 \sinh \frac{2a_i + a_j - m + \epsilon_+}{2} \sinh \frac{\pm a_i + \pm a_j - m}{2}}{2 \sinh(\pm a_i) \sinh(\pm a_j) \sinh(\pm a_i + \epsilon_+) \sinh(\pm a_j + \epsilon_+)} \right)^{\frac{1}{2}} \prod_{1 \leq k \neq i, j \leq n} \frac{2 \sinh(\pm a_k) \sinh(\pm a_k + \epsilon_+)}{2 \sinh(\pm a_k + \epsilon_+)}.$$  

(5.22)

$$Z'_{ij}(a) = \left( \frac{2 \sinh \frac{2a_i - a_j - m + \epsilon_+}{2} \sinh \frac{\pm a_i + \pm a_j + m}{2}}{2 \sinh(\pm a_i) \sinh(\pm a_j) \sinh(\pm a_i + \epsilon_+) \sinh(\pm a_j + \epsilon_+)} \right)^{\frac{1}{2}} \prod_{1 \leq k \neq i, j \leq n} \frac{2 \sinh(\pm a_k) \sinh(\pm a_k + \epsilon_+)}{2 \sinh(\pm a_k + \epsilon_+)}.$$  

(5.23)
The quantities $Z_{\text{mono}}^{\prime}(a)$ and $Z_{\text{mono}}^{\prime\prime}(a)$ are the monopole screening contributions, which we will compute using SQMs in section 5.2.2. For $m = \epsilon_+ = 0$, from S-duality, we expect the vev (5.2.2) to reduce to the character of the adjoint representation of $SO(2n+1)$. Namely we expect the relation

$$\langle T^{a_1}_{\text{adj}} \rangle = \sum_{1 \leq i < j \leq n} (e^{b_i+b_j} + e^{-b_i-b_j} + e^{b_i+b_j} + e^{-b_i-b_j}) + \sum_{i=1}^n (e^{b_i} + e^{-b_i}) + n. \quad (5.24)$$

to hold.

### 5.2.1 $V$

We first compute the contribution $Z_{\text{mono}}(a)$ in (5.18). The brane configuration and the SQM quiver for the $v = 0$ sector are shown in figures 22a and 22b, respectively. The supersymmetric index consists of two contributions, corresponding to the two components $O(1)_+$ and $O(1)_-$ of $O(1)$. These contributions are

$$Z^+_V(v = 0) = \prod_{i=1}^n \frac{2 \sinh \frac{\pm a_i + m}{2}}{2 \sinh \frac{\pm a_i + \epsilon_+}{2}}, \quad Z^-_V(v = 0) = \prod_{i=1}^n \frac{2 \cosh \frac{\pm a_i + m}{2}}{2 \cosh \frac{\pm a_i + \epsilon_-}{2}}. \quad (5.25)$$

The supersymmetric index is then

$$Z_V(v = 0) = \frac{1}{2} (Z^+_V(v = 0) + Z^-_V(v = 0))$$

$$= \frac{1}{2} \left( \prod_{i=1}^n \frac{2 \sinh \frac{\pm a_i + m}{2}}{2 \sinh \frac{\pm a_i + \epsilon_+}{2}} + \prod_{i=1}^n \frac{2 \cosh \frac{\pm a_i + m}{2}}{2 \cosh \frac{\pm a_i + \epsilon_-}{2}} \right). \quad (5.26)$$

We chose the overall sign by hand so that (5.20) holds when we set $m = \epsilon_+ = 0$. In this case also there is no extra term, and hence $Z_{\text{mono}}(a)$ in (5.18) is given by (5.26).

When $n = 1$, the monopole screening contribution should be equal to the one which arises in $\langle T_{\text{adj}} \rangle$ of the $\mathcal{N} = 2^*$ SU(2) gauge theory. The monopole screening contribution $Z^{}_{\text{mono}}^{SU(2)}$ is given in (4.29), and (4.29) as a function equals (5.26) with $2a_1 = a$ specialized to $n = 1$ due to trigonometric identities, even though they have different expressions.
SO(5) versus USp(4). We now compare \( \langle T_{\Lambda^2 V}^{SO(5)} \rangle \) of the \( \mathcal{N} = 2^* \) SO(5) gauge theory and \( \langle T_{V}^{USp(4)} \rangle \) of the \( \mathcal{N} = 2^* \) USp(4) gauge theory. We expect that they are non-trivially related because of the isomorphism of the Lie algebras \( so(5) \approx usp(4) \).

The 1-loop determinants in \( \langle T_{\Lambda^2 V}^{SO(5)} \rangle \) are the specializations of (4.19) and (4.20) to \( n = 2 \):

\[
Z_{12}^{SO(5)}(a_1,a_2) = \left( \frac{2 \sinh \frac{(a_1 + a_2) - m \pm \epsilon_+}{2} \sinh \frac{a_1 + a_2 - m}{2}}{2 \sinh \frac{(a_1 + a_2) + 2 \epsilon_+}{2} \sinh \frac{a_1 + a_2 + 2 \epsilon_+}{2}} \right)^{\frac{1}{2}},
\]

\[
Z_{12}^{SO(5)}(a_1,a_2) = \left( \frac{2 \sinh \frac{(a_1 - a_2) - m \pm \epsilon_+}{2} \sinh \frac{a_1 - a_2 - m}{2}}{2 \sinh \frac{(a_1 - a_2) + 2 \epsilon_+}{2} \sinh \frac{a_1 - a_2 + 2 \epsilon_+}{2}} \right)^{\frac{1}{2}}.
\]

On the other hand the 1-loop determinants in \( \langle T_{V}^{USp(4)} \rangle \) can be obtained from (5.19) as

\[
Z_{1}^{USp(4)}(\tilde{a}_1,\tilde{a}_2) = \left( \frac{2 \sinh \frac{2\tilde{a}_1 - m \pm \epsilon_+}{2} \sinh \frac{2\tilde{a}_1 - \tilde{a}_2 - m}{2}}{2 \sinh (\pm \tilde{a}_1) \sinh (\pm \tilde{a}_1 + \epsilon_+) \sinh (\pm \tilde{a}_1 + \tilde{a}_2 + \epsilon_+)} \right)^{\frac{1}{2}},
\]

\[
Z_{2}^{USp(4)}(\tilde{a}_1,\tilde{a}_2) = \left( \frac{2 \sinh \frac{2\tilde{a}_2 - m \pm \epsilon_+}{2} \sinh \frac{2\tilde{a}_1 - \tilde{a}_2 - m}{2}}{2 \sinh (\pm \tilde{a}_2) \sinh (\pm \tilde{a}_2 + \epsilon_+) \sinh (\pm \tilde{a}_1 + \tilde{a}_2 + \epsilon_+)} \right)^{\frac{1}{2}},
\]

where \( \tilde{a}_1, \tilde{a}_2 \) are the Coulomb branch moduli of USp(4). We find the relations among the one-loop determinants

\[
Z_{12}^{SO(5)}(\tilde{a}_1 + \tilde{a}_2, \tilde{a}_1 - \tilde{a}_2) = Z_{1}^{USp(4)}(\tilde{a}_1, \tilde{a}_2), \quad Z_{12}^{SO(5)}(\tilde{a}_1 + \tilde{a}_2, \tilde{a}_1 - \tilde{a}_2) = Z_{2}^{USp(4)}(\tilde{a}_1, \tilde{a}_2).
\]

Let us now compare the monopole screening contributions to \( \langle T_{\Lambda^2 V}^{SO(5)} \rangle \) and \( \langle T_{V}^{USp(4)} \rangle \). The monopole screening contribution to \( \langle T_{\Lambda^2 V}^{SO(5)} \rangle \) is given by the contour integral (4.22) specialized to \( n = 2 \). The reducible representation \( \wedge^2 V \) of usp(4) contains a non-trivial irreducible representation whose Dynkin label is [0,1]. The monopole screening contribution to the vev of the ’t Hooft operator \( \langle T_{\Lambda^2 V}^{SO(5)} \rangle \) that corresponds to the irreducible representation is obtained by subtracting an extra term from \( Z_{\Lambda^2 V}^{SO(5)}(v = 0) = (4.22) \). Since we consider the irreducible representation corresponding to the Dynkin label [0, 1] instead of the reducible representation \( \wedge^2 V \), we add 1 to (4.24) and consider the extra term

\[
Z_{\text{extra}}^{SO(5)} = (4.24) + 1 = \frac{2 \cosh(m) + \cosh(\epsilon_+)}{2 \cosh \frac{m \pm \epsilon_+}{2}}.
\]

Then the monopole contribution in the expectation value of \( \langle T_{\Lambda^2 V}^{SO(5)} \rangle \) is given by

\[
Z_{\text{mono}}^{SO(5)} = Z_{\Lambda^2 V}^{SO(5)}(v = 0) - Z_{\text{extra}}^{SO(5)}.
\]

On the other hand, the monopole screening contribution to \( \langle T_{V}^{USp(4)} \rangle \) is (5.26) specialized to \( n = 2 \). Indeed we have the following relation for monopole screening contributions

\[
Z_{\text{mono}}^{SO(5)}(\tilde{a}_1 - \tilde{a}_2, \tilde{a}_1 - \tilde{a}_2) = Z_{\text{mono}}^{USp(4)}(\tilde{a}_1, \tilde{a}_2).
\]
The results (5.31) and (5.34) give the relation between the vevs

\[
\langle T^{SO(5)}_{[0,1]} \rangle \bigg|_{(a_1,a_2)\rightarrow(\tilde{a}_1+\tilde{a}_2,\tilde{a}_1-\tilde{a}_2)} = \langle T^{USp(4)}_V \rangle.
\]

The relations between the SO(5) and USp(4) parameters are the opposite for the electric \((a_i\text{ and }\tilde{a}_i)\) and magnetic \((b_i\text{ and }\tilde{b}_i)\) parameters because the simple roots and coroots of SO(5) are the simple coroots and roots of USp(4), respectively.

### 5.2.2 \(\wedge^2 V\)

The expectation value \(\langle T^{\wedge^2 V}_\chi \rangle\) of (5.21) contains two types of monopole screening contribution, \(Z'_{\text{mono},i}(a)\) and \(Z''_{\text{mono},i}(a)\).

We first consider \(Z'_{\text{mono},i}(a)\). The brane configuration and the SQM quiver for \(Z'_{\text{mono},i}(a)\) are given in figure 23. The SQM quiver is the same as the one in figure 22b except that the number of the hypermultiplets is \(n-1\) in this case. Utilizing the result (5.26) the supersymmetric index of the SQM becomes

\[
Z'_{\wedge^2 V,i}(\mathbf{v} = e_i) = \frac{1}{2} \left( \prod_{1\leq j(\neq i)\leq n} 2 \sinh \frac{\pm a_j + m}{2} \cosh \frac{\pm a_j + m}{2} + \prod_{1\leq j(\neq i)\leq n} \frac{2 \sinh \frac{\pm a_j + m}{2} \cosh \frac{\pm a_j + m}{2}}{2 \sinh \frac{\pm a_j + \epsilon_+}{2}} \right).
\]

In this case there is no extra term, and \(Z'_{\text{mono},i}(a)\) in (5.21) is given by (5.36).

For the other contribution \(Z''_{\text{mono},i}(a)\), the brane configuration and the SQM quiver are depicted in figure 24. The monopole screening contribution \(Z''_{\text{mono}}(a)\) is given by the supersymmetric index of the SQM up to an extra term. The gauge group of the SQM is the non-connected group O(2) which has two connected components. The first component O(2)_+ consists of elements with unit determinant, while the elements of the other component O(2)_- have determinants equal to \(-1\). The supersymmetric index receives contributions from the two components. The contribution from O(2)_+ is

\[
Z''_{\wedge^2 V,+,+}(\mathbf{v} = 0) = \oint_{J_{K(n)}} \frac{d\phi}{2\pi i} 2 \sinh(\epsilon_+) \prod_{i=1}^m \frac{2 \sinh(\pm a_i + m)}{2 \sinh \frac{\pm a_i + \epsilon_+}{2}} \prod_{i=1}^n \frac{2 \sinh(\pm a_i + \epsilon_+)}{2 \sinh \frac{\pm a_i + \epsilon_+}{2}}.
\]
Figure 24. (a): the brane configuration for the monopole screening sector $v = 0$ of the ’t Hooft operator $T_{\lambda,\bar{z} V}$. (b): the corresponding SQM quiver, which computes $Z_{\text{mono}}''$.

and that from O(2)$_-$ is

$$Z_{\lambda,\bar{z} V^-}''(v = 0) = \frac{2 \cosh(\epsilon_+) \prod_{i=1}^{n} 2 \sinh(\pm a_i + m)}{2 \cosh \frac{m - \epsilon_+}{2} \prod_{i=1}^{n} 2 \sinh(\pm a_i + \epsilon_+)}.$$

The contribution from the O(2)$_+$ sector is given by a contour integral and the JK residue computation yields

$$Z_{\lambda,\bar{z} V^+}''(v = 0) = \sum_{i=1}^{n} \frac{2 \sinh \left(\frac{(2a_i - \epsilon_+ + m)}{2}\right) \prod_{j \neq i}^{n} 2 \sinh \left(\frac{(a_i + a_j - \epsilon_+ + m)}{2}\right) 2 \sinh \left(\frac{(a_i - a_j - \epsilon_+ + m)}{2}\right) 2 \sinh \left(\frac{-a_i + a_j + 2\epsilon_+}{2}\right)}{2 \sinh(-a_i) 2 \sinh(a_i + \epsilon_+)} \prod_{j \neq i}^{n} 2 \sinh \left(\frac{(a_i + a_j + \epsilon_+ + m)}{2}\right) 2 \sinh \left(\frac{(a_i - a_j - \epsilon_+ + m)}{2}\right) 2 \sinh \left(\frac{-a_i + a_j + 2\epsilon_+}{2}\right)},$$

which is independent of the JK parameter $\eta$. Since the monopole screening contribution in $\langle T_{\lambda,\bar{z} V} \rangle$ does not have an extra term, we can apply the extra term prescription to the monopole screening contribution $Z_{\text{mono}}''(a)$ in $\langle T_{\lambda,\bar{z} V} \rangle$. The contribution from O(2)$_-$ has no integration but contains a non-trivial Coulomb branch moduli independent term, i.e., an extra term defined in section 2.5, which we believe is given by

$$Z_{\text{extra}} = \frac{2 \cosh(\epsilon_+)}{2 \cosh \frac{m + \epsilon_+}{2}}.$$

We explicitly checked this for $n = 1, 2, 3, 4, 5$. Hence the monopole screening contribution $Z_{\text{mono}}''(a)$ in (5.21) is

$$Z_{\text{mono}}''(a) = \frac{1}{2} \left( Z_{\lambda,\bar{z} V^+}''(v = 0) + Z_{\lambda,\bar{z} V^-}''(v = 0) \right) - Z_{\text{extra}},$$

where $Z_{\text{extra}} = \frac{1}{2} Z_{\text{extra}}$.

For $n = 1$, we expect that $\langle T_{\lambda,\bar{z} V}^{\text{USp}(2)} \rangle$ equals $\langle T_{\lambda,\bar{z} V}^{\text{SU}(2)} \rangle$. The monopole contribution to the former, given by the specialization of (5.41) to $n = 1$, indeed coincides precisely with (4.29) with $2a_1 = a$. This is evidence for the validity of (5.41) and for the extra term prescription we proposed in section 2.5.

---

28 See footnote 18.
The Moyal product $\langle T_V \rangle * \langle T_V \rangle$ takes the same form as (5.6), but $Z_i(a)$ and $Z_{\text{mono}}(a)$ are given by (5.19) and (5.26) respectively. There are three types of monopole screening sectors: $v = \pm e_i \pm e_j$ ($1 \leq i < j \leq n$), $v = \pm e_i$ ($1 \leq i \leq n$), and $v = 0$. We will compute their contributions from the supersymmetric indices of the corresponding SQMs and compare them with the Moyal product. We will determine the overall signs of the indices by requiring that the index reduces, after setting $m = \epsilon_+ = 0$, to the square of a character

$$
\langle T_V \rangle * \langle T_V \rangle \bigg|_{m=\epsilon_+=0} = \sum_{i=1}^{n}(e^{2b_i} + e^{-2b_i} + 2e^{b_i} + 2e^{-b_i})
+ \sum_{1 \leq i < j \leq n} \left(2e^{b_i+b_j} + 2e^{-b_i-b_j} + 2e^{b_i-b_j} + 2e^{-b_i+b_j}\right) + 2n + 1.
$$

$v = \pm e_i \pm e_j$ for $1 \leq i < j \leq n$. First we consider the sector $v = \pm e_i \pm e_j$ for $1 \leq i < j \leq n$. The brane configuration for the sector $v = e_{n-1} + e_n$ and the quiver diagram for the monopole screening sector are depicted in figures 25a and 25b. The supersymmetric index again consists of two contributions. The contribution from the

\[ Z_{\text{mono}}(v = e_{n-1} + e_n; a) \]

in the Moyal product is computed by

$$
Z_{n-1}(a + \epsilon_+ e_n)Z_n(a - \epsilon_+ e_{n-1}) + Z_{n-1}(a - \epsilon_+ e_n)Z_n(a + \epsilon_+ e_{n-1})
= Z_{(n-1)n}(a)Z_{\text{mono}}(v = e_{n-1} + e_n; a),
$$

where $Z_{(n-1)n}(a)$ is (5.22) with $i = n-1$ and $j = n$. We find that $Z_{\text{mono}}(v = e_{n-1} + e_n; a)$ is again precisely the right hand side of (4.40) as expected.

$v = \pm e_i$. Next we consider the sector $v = \pm e_i$. The brane configuration and the quiver diagram for the monopole screening sector are depicted in figures 25a and 25b. The supersymmetric index again consists of two contributions. The contribution from the
The overall sign of each contribution was chosen so that we obtain
\[ \left[ \frac{1}{2} \left( Z_+(v = \pm e_i, \zeta) + Z_-(v = \pm e_i, \zeta) \right) \right]_{m = e_i = 0} = 2, \] (5.46)

which is the coefficient of $e^{\pm b_i}$ in (5.42). The supersymmetric index is
\[ Z(v = \pm e_i, \zeta) = \frac{1}{2} \left( Z_+(v = \pm e_i, \zeta) + Z_-(v = \pm e_i, \zeta) \right). \] (5.47)

By evaluating the JK residues we find the relation
\[ Z(v = \pm e_i, \zeta) = Z_{\text{mono}}(a - \epsilon_+ e_i) + Z_{\text{mono}}(a + \epsilon_+ e_i) \] (5.48)

for both $\zeta > 0$ and $\zeta < 0$, where the function $Z_{\text{mono}}$ is given in (5.26). This is indeed the
monopole screening contribution to the Moyal product (5.6) from the sector $v = \pm e_i$.

$\mathbf{v} = \mathbf{0}$. The other sector is $\mathbf{v} = \mathbf{0}$. The brane configuration and the quiver diagram for the SQM describing the monopole screening contribution are depicted in figures 26a and 26b, respectively. Again the supersymmetric index consists of two contributions. The contribution from the $O(2)_+ - U(1)$ sector is
\[ Z_+(v = 0, \zeta) = \oint_{JK(\zeta)} d\phi_1 d\phi_2 \frac{(2 \sinh(\epsilon_+))^2}{2 \sinh \frac{m-\epsilon_+}{2}} \left( 2 \sinh \frac{\pm \phi_1 + \phi_2 + m}{2} \prod_{i=1}^n 2 \sinh \frac{\pm \phi_1 + \phi_2 + \epsilon_+}{2} \prod_{i=1}^n 2 \sinh \frac{\pm \phi_1 + \phi_2 + \epsilon_+}{2} \right), \] (5.49)
The contribution from the $O(2)_- - U(1)$ sector is

$$Z_-(v = 0, \zeta) = -\oint_{J_K(\zeta)} \frac{d\phi}{2\pi i} \frac{2\sinh(\epsilon_+) \cdot 2\cosh(\epsilon_+)}{2\sinh(\pm \phi + m) \prod_{i=1}^n 2\sinh(\pm a_i + m)}.$$  

(5.50)

We chose the overall signs for (5.49) and (5.50) so that we reproduce the constant term in (5.42) after setting $m = \epsilon_+ = 0$, namely

$$\left[\frac{1}{2} (Z_+(v = 0, \zeta) + Z_-(v = 0, \zeta))\right]_{m=\epsilon_+=0} = 2n + 1.$$  

(5.51)

The supersymmetric index is then given by

$$Z(v = 0, \zeta) = \frac{1}{2} (Z_+(v = 0, \zeta) + Z_-(v = 0, \zeta)).$$  

(5.52)

The Moyal product of the $v = 0$ sector in (5.6) is the last line of (5.6). By explicitly evaluating (5.52) we find the relation

$$Z(v = 0, \zeta) = \sum_{i=1}^n \left( Z_i(a + \epsilon_i e_i)^2 + Z_i(a - \epsilon_i e_i)^2 \right) + Z_{\text{mono}}(a)^2.$$  

(5.53)

for both $\zeta > 0$ and $\zeta < 0$.

6 Conclusion and discussion

In this paper we calculated by supersymmetric localization the expectation values of ’t Hooft operators on $S^1 \times \mathbb{R}^3$ in theories with gauge groups $U(N)$, $SO(N)$ and $USp(N)$. Let us here specify the magnetic charge of an operator by a representation of the Langlands dual group. For the SQCD and the $\mathcal{N} = 2^*$ theory with gauge group $U(N)$, we computed the expectation values in the cases $\Lambda^2 V$ and $\Lambda^2 \mathcal{V}$. We also studied the product $\Lambda^2 V \times \Lambda^2 \mathcal{V}$, i.e., we computed the correlator of an ’t Hooft operator with the charge corresponding to $\Lambda^2 V$ and another operator with the charge corresponding to $\Lambda^2 \mathcal{V}$. For the $SO(N)$ SQCD we did the computation for $V \times V$. For the $SO(N)$ $\mathcal{N} = 2^*$ theory we computed the vev for $\Lambda^2 V$ and $V \times V$. For the $USp(N)$ SQCD we studied $V$ and $V \times V$. For the $USp(N)$ $\mathcal{N} = 2^*$ theory we computed the vevs for $V$, $\Lambda^2 V$, and $V \times V$.

As we mentioned in the introduction, we did not distinguish different global structures (gauge group topologies and discrete theta angles [25]) associated with a given gauge algebra. The determination of the precise global structure associated with a brane system is an interesting and delicate problem. The recent work [41] and its sequel may shed light on this. The global structures that arise in the brane constructions we consider must admit at least ’t Hooft operators whose magnetic charges correspond to the anti-symmetric representations $\Lambda^k V$.

Let us comment on the global structures of “$SO(N)$ gauge theories” realized by branes and an orientifold. In some of such realizations the global structure is actually that...
of $O(N)$.\footnote{There are exceptions. For example the gauge group of a theory with spinor matter \cite{42} cannot be $O(N)$.} For example it is believed that D3-branes on top of an orientifold 3-plane ($O3^-$ or $\tilde{O}3^-$) lead to the $O(N)$, rather than $SO(N)$, gauge group \cite{43}. Also, the ADHM construction of $k$ $USp$ instantons requires $O(k)$, rather than $SO(k)$, as the ADHM gauge group, and this implies that the gauge group for $k$ D-instantons on top of an orientifold 3-plane ($O3^+$) realizes $O(k)$ \cite{33}. The following observation suggests that the gauge group arising from our brane realizations of “$SO(2n)$ gauge theories” is also $O(2n)$ (or its covering). For $SO(2n)$ the representation $\wedge^n V$ is reducible, to the sum of (imaginary-)self-dual and (imaginary-)anti-self-dual parts. But for $O(2n)$ it is irreducible. We can construct the ’t Hooft operator corresponding to $\wedge^n V$ by $n$ D2-branes ending on a single NS5'-brane, as we explained in section 2. But there appears to be no freedom to split the 5-brane into two, implying that the gauge group is more likely to be $O(2n)$ than $SO(2n)$.

In the main text we did not study wall-crossing in the $SO$/$USp$ theories, and this is related to the subtleties studied in appendix C. The brane construction in 2.2 makes it plausible that conjectures (ii) and (ii)' in section 2.6 extend to the $SO$/$USp$ SQCDs and that wall-crossing occurs. But to confirm this we need to consider the product of different kinds of operators. The simplest choice would be $T_V \cdot T_{\wedge^2 V}$, but the computations involving $T_{\wedge^2 V}$ are subtle as discussed in appendix C. The subtleties may be avoided in cases of a small number of flavors and the monopole screening contributions in some examples are computed in appendix C. However, the monopole screening contributions do not exhibit wall-crossings in those cases with a small number of flavors, which was also the case for $U(N)$ SQCDs \cite{13}. It would be important to generalize the results by sorting out these subtleties and unambiguously determine if the $SO$/$USp$ SQCDs and more general conformal or asymptotically gauge theories exhibit wall-crossing. This might involve a careful extension of the analysis of \cite{18} to the cases with non-abelian gauge groups without FI parameters and with higher-order poles at infinity. A study of wall-crossing based on naive computations is summarized in appendix C.3. Also, it would be desirable to give a proper understanding of the extra term prescription in section 2.5. According to the proposal in \cite{12}, corrections to the monopole screening contributions computed by the JK residue prescription are the contributions to the supersymmetric index from the Coulomb or the mixed Higgs-Coulomb branches of the SQM. In fact the application of the extra term prescription to the $SU(2)$ SQCD with $N_f = 4$ flavors was able to reproduce the Coulomb branch contribution in \cite{12} as we have seen in section 2.5. We suspect that the extra terms computed in other examples may also correspond to the correction terms from ground states on a Coulomb branch. We regard it as an important open problem to establish a clear understanding of the relation between the corrections and the extra terms. Also the analogy with instanton partition functions implies that the extra term may not be always independent from Coulomb branch moduli, which has been also pointed out in \cite{12}. So far we have seen that the extra terms for monopole screening contributions in ’t Hooft operators in the rank-2 antisymmetric representaion of Langlands dual groups in $\mathcal{N} = 2^*$ $SO(N)$ and $USp(2N)$ gauge theories are simply Coulomb branch independent parts of the supersymmetric indices of SQMs. The argument in section 2.5 suggests that a Coulomb branch dependent extra term may possibly arise when we consider an ’t Hooft operator in a higher rank antisymmetric rep-
presentation (e.g. rank-3 antisymmetric representation) in $\mathcal{N} = 2^*$ SO($N$) and USp(2$N$) gauge theories and it would be interesting to check if this is indeed the case.

Before this work, localization for 't Hooft operators, especially with monopole screening, had been done only for SU($N$) and U($N$) gauge groups; consequently applications such as [38, 44–49] and section 8.2 of [39] had been limited to these groups. Our results here should be useful when extending these applications to SO($N$) and USp($N$). It would also be interesting to explore S-duality between Wilson and 't Hooft operators on $S^4_b$ [50] and $S^1 \times S^3$ [51] for various gauge groups and for $\mathcal{N} = 2^*$ and SQCDs. This paper only treated the hypermultiplets only in special representations of the gauge groups; it would be desirable to generalize to other representations along the line of [52].

Another natural extension of [13] and the present work is to consider exceptional gauge groups. The set-ups for instanton counting with exceptional gauge groups in [53–66] may be useful. Also, the 't Hooft operators in SO/USp SQCD with the magnetic charges corresponding to $\wedge^2 V$ and higher anti-symmetric representations, which exhibit some subtleties and of which we did a preliminary study in appendix C, deserve further investigation. Finally, as explained in section 2.4, our SQMs arise from D2-branes bounded by NS5- and NS5'-branes. It would be nice to extend the 2d $\mathcal{N} = (0, 4)$ brane box models of [32] by including orientifolds and also by allowing D-branes to end on NS5(')-branes. Our SQMs would be the dimensional reduction of such 2d theories.

A Useful facts about U($N$), SO($N$), and USp($N$)

In this appendix we collect some relevant facts that we use in the main text. For the basic notions such as various lattices, we recommend [67] and appendix A of [68].

A.1 U($N$)

We denote by $e_i$ ($i = 1, \ldots, N$) the orthonormal basis of the Cartan subalgebra of U($N$), identified with its dual. We summarize the information about the Lie algebra of U($N$) in the following table.

| simple (co)roots | $e_i - e_{i+1}$ ($1 \leq i \leq N - 1$) |
| (co)roots | $e_i - e_j$ ($i \neq j$) |
| fundamental (co)weights | $e_1 + \ldots + e_j$ ($1 \leq j \leq N$) |
| Weyl group | $S_N$ |

The Weyl group acts by permuting $e_i$ ($i = 1, \ldots, N$).
For the ’t Hooft operator corresponding to the rank-$k$ anti-symmetric representation $\Lambda^k V$ of $U(N)$, we imitate the convention in [10] and write $B = e_{N-k+1} + e_{N-1} + \ldots + e_N$ ($k = 1, \ldots, N$) to specify their magnetic charges. For the ’t Hooft operators corresponding to the complex conjugate of the rank-$k$ anti-symmetric representation $\Lambda^k V$, we write $B = -e_1 - e_2 - \ldots - e_k$ ($k = 1, \ldots, N$) to specify their magnetic charges. The representations $\Lambda^k V$ and $\Lambda^k V$ are minuscule, in the sense that all the non-zero weights are in a single Weyl group orbit. The adjoint representation $V \otimes V$ is quasi-minuscule [69] in the sense that all the non-zero weights are in a single Weyl group orbit.\footnote{For a general gauge group $G$, if the magnetic charge of an ’t Hooft operator corresponds to a minuscule representation of the Langlands dual $G'$, the vev is completely determined by the one-loop formulas (B.3) and (B.4). If the magnetic charge corresponds to a quasi-minuscule representation, the vev is determined by the one-loop formulas except a single $b_i$-independent term which is a monopole screening contribution.}

The (co)character lattice of $U(N)$ is given by

$$\Lambda_{\text{char}}(U(N)) = \Lambda_{\text{char}}(U(N)) = \bigoplus_{i=1}^N \mathbb{Z} e_i.$$ (A.1)

**A.2 $SO(2n)$**

We denote by $e_i$ ($i = 1, \ldots, n$) the orthonormal basis of the Cartan subalgebra identified with its dual. We summarize the information about the Lie algebra of $SO(2n)$ with $n \geq 3$ in the following table.

| simple (co)roots | $e_i - e_{i+1}$ ($i = 1, \ldots, n - 1$), $e_{n-1} + e_n$ |
|------------------|----------------------------------------------------------|
| (co)roots        | $\pm e_i \pm e_j$ ($1 \leq i < j \leq n$, signs uncorrelated) |
| fundamental (co)weights | $e_1 + \ldots + e_j$ ($1 \leq j \leq n - 2$), $\frac{1}{2} \sum_{i=1}^{n-1} e_i \pm e_n$ |
| Weyl group       | $S_n \ltimes (\mathbb{Z}_2)^{n-1}$ |

The Weyl group acts by permuting $e_i$ ($i = 1, \ldots, N$) as well as by flipping the signs of an even number of $e_i$'s simultaneously.

For the ’t Hooft operators corresponding to the first $n - 2$ fundamental coweights and anti-symmetric representations, we use the coweight $B = e_{n-i+1} + e_{n-i+2} + \ldots + e_n$ ($i = 1, \ldots, n - 2$), which is Weyl equivalent to the coweights, to specify their magnetic charges. The vector representation $V$ is minuscule. The adjoint representation $\Lambda^* V$ is quasi-minuscule.

The compact real form $SO(2n)$ is neither simply connected nor of adjoint type.\footnote{A semisimple Lie group is said to be of adjoint type if its center is trivial.} The cocharacter lattice is given by

$$\Lambda_{\text{cochar}}(SO(2n)) = \Lambda_{\text{char}}(SO(2n)) = \bigoplus_{i=1}^N \mathbb{Z} e_i.$$ (A.2)

For $n \geq 2$, its universal cover $Spin(2n)$ is a double cover of $SO(2n)$, corresponding to the fact that $\Lambda_{\text{coweight}}(SO(2n))/\Lambda_{\text{cochar}}(SO(2n)) = \pi_1(SO(2n)) = \mathbb{Z}_2$. The center of $SO(2n)$ is $\Lambda_{\text{cochar}}(SO(2n))/\Lambda_{\text{coroot}}(SO(2n)) = \mathbb{Z}_2$.\footnote{The center of $Spin(2n)$ is $\mathbb{Z}_2 \times \mathbb{Z}_2$ for $n$ even, and is $\mathbb{Z}_4$ for $n$ odd (and $\geq 3$).}
A.3 SO(2n + 1)

We denote by $e_i$ ($i = 1, \ldots, n$) the orthonormal basis of the Cartan subalgebra identified with its dual. We summarize the information about the Lie algebra of SO(2n + 1):

| Type                  | Information                                      |
|-----------------------|--------------------------------------------------|
| simple roots          | $e_i - e_{i+1}$ ($i = 1, \ldots, n-1$), $e_n$   |
| roots                 | $\pm e_i \pm e_j$ ($1 \leq i < j \leq n$), $\pm e_i$ ($i = 1, \ldots, n$) |
| simple coroots        | $e_i - e_{i+1}$ ($i = 1, \ldots, n-1$), $2e_n$  |
| coroots               | $\pm e_i \pm e_j$ ($1 \leq i < j \leq n$), $\pm 2e_i$ ($i = 1, \ldots, n$) |
| fundamental weights   | $e_1 + \ldots + e_j$ ($1 \leq j \leq n-1$), $\frac{1}{2} \sum_{i=1}^{n-1} e_i + e_n$ |
| fundamental coweights | $e_1 + \ldots + e_i$ ($1 \leq i \leq n$)        |
| Weyl group            | $S_n \ltimes (\mathbb{Z}_2)^n$                   |

The double signs in roots and coroots are uncorrelated. The Weyl group acts by permuting $e_i$ ($i = 1, \ldots, N$) as well as by flipping the signs of an arbitrary number of $e_i$’s simultaneously.

For the ’t Hooft operators corresponding to the fundamental coweights and the anti-symmetric representations $\wedge^k V$ of USp(2n), we use

$$B = e_{n-k+1} + e_{n-i+2} + \ldots + e_n \quad (k = 1, \ldots, n) \quad (A.3)$$

to specify their magnetic charges. The vector representation $V$ of USp(2n) is minuscule. The adjoint representation of USp(2n), which is obtained from $\wedge^2 V$ by subtracting a singlet corresponding to the symplectic form, is quasi-minuscule for $n \geq 2$.

The compact real form SO(2n + 1) is of adjoint type, and its Langlands dual USp(2n) is simply connected. The cocharacter lattice is given by

$$\Lambda_{\text{cochar}}(\text{SO}(2n + 1)) = \Lambda_{\text{char}}(\text{USp}(2n)) = \Lambda_{\text{weight}}(\text{USp}(2n)) = \bigoplus_{i=1}^{N} \mathbb{Z}e_i. \quad (A.4)$$

A.4 USp(2n)

The relevant information about the Lie algebra of USp(2n) is obtained from the table given above for the Langlands dual SO(2n + 1) by exchanging roots and coroots, as well as by exchanging weights and coweights.

For the ’t Hooft operators corresponding to the fundamental coweights and the anti-symmetric representations of SO(2n + 1), we use the coweight

$$B = e_{n-i+1} + e_{n-i+2} + \ldots + e_n \quad (i = 1, \ldots, n-1) \quad (A.5)$$

to specify their magnetic charges. The vector representation $V$ of SO(2n + 1) is quasi-minuscule.

The compact real form USp(2n) is simply connected, and its Langlands dual SO(2n + 1) is of adjoint type. The cocharacter lattice is given by

$$\Lambda_{\text{cochar}}(\text{USp}(2n)) = \Lambda_{\text{char}}(\text{SO}(2n + 1)) = \Lambda_{\text{root}}(\text{SO}(2n + 1)) = \bigoplus_{i=1}^{N} \mathbb{Z}e_i \quad (A.6)$$
B Formulas for one-loop determinants

In this appendix we collect useful formulas which we use in the computations of the expectations values of 't Hooft operators.

B.1 One-loop determinants for 't Hooft operator vevs in 4d $\mathcal{N} = 2$ theories

The expectation value of an 't Hooft line operator with magnetic charge $B$ takes the form \[ \langle T_B \rangle = \sum_{v \in \mathcal{B}_{\text{cort}}} \epsilon_{\text{cort}} v \left( v \cdot b \right) Z_{\text{1-loop}}(a, m, \epsilon_+; B, v), \] \( B.1 \)

where $v$ labels monopole screening sectors. The total one-loop determinant is the product \[ Z_{\text{1-loop}}(a, m, \epsilon_+; B, v) = Z_{\text{vm}}^{\text{1-loop}}(a, \epsilon_+; v) \prod_f Z_{\text{hm}, R_f}^{\text{1-loop}}(a, m_f, \epsilon_+; v), \] \( B.2 \)

of the contribution $Z_{\text{vm}}^{\text{1-loop}}$ from the vector multiplet for gauge group $G$ and the contributions $Z_{\text{hm}, R_f}^{\text{1-loop}}$ from matter hypermultiplets in the representations $R_f$ of $G$. The one-loop determinant of the vector multiplet is \[ Z_{\text{vm}}^{\text{1-loop}}(a, \epsilon_+; v) = \prod_{\alpha \in \text{root}} \left[ 2 \sinh \left( \frac{\alpha(a) + |\alpha(v)| - 2k \epsilon_+}{2} \right) \right]^{-\frac{1}{2}}, \] \( B.3 \)

where the symbol “root” denotes the set of roots. The one-loop determinant of the hypermultiplet in a representation $R$ of $G$ with a mass parameter $m$ is \[ Z_{\text{hm}, R}^{\text{1-loop}}(a, m, \epsilon_+; v) = \prod_{\rho \in \Delta(R)} \left[ 2 \sinh \left( \frac{\rho(a) - m + |\rho(v)| - 1 - 2k \epsilon_+}{2} \right) \right]^{\frac{1}{2}}, \] \( B.4 \)

where $\Delta(R)$ is the set of the weights in $R$.

B.2 One-loop determinants in SQMs

In terms of one-loop determinants for $\mathcal{N} = (0, 4)$ supermultiplets, the supersymmetric index of the SQM takes the form \[ Z = \pm \oint_{JK} Z_{\text{vec}} Z_{\text{hyp}} Z_{\text{fer}}. \] \( B.5 \)

We denote the gauge group and the flavor symmetry group by $H$ and $F$, respectively. For the JK residue prescription indicated in (B.5), we refer the reader to the early references [16–18, 70] and our previous work [13]. We choose the overall sign in (B.5) by hand in each example. For the precise one-loop determinants, we use the formulas given in [16, 71].

\(^{33}\) We use the short-hand notation $2 \sinh \frac{a+\pm b}{2} \equiv (2 \sinh \frac{a+\pm b}{2})(2 \sinh \frac{a-\pm b}{2})$.

\(^{33}\) The poles that contribute to the contour integral (B.5) via the residue prescription depend crucially on the precise charge assignments associated with the sinh factors in the denominator of the integrand. For example, the expression $1/(2 \sinh \frac{a-\pm b}{2})$ corresponding to $\text{U}(1)$ charge $+1$ and another expression $-1/(2 \sinh \frac{a-\pm b}{2})$ corresponding to charge $-1$ lead to different results.
For the $\mathcal{N} = (0,4)$ vector multiplet the one-loop determinant is given by
\begin{equation}
Z_{\text{vec}} = \frac{1}{|W|} \prod_{i=1}^{r} \frac{d\phi_i}{2\pi i} \prod_{\alpha \in \text{root}} \frac{2 \sinh(\phi)}{2} \prod_{\alpha \in \Delta(\text{adj})} \frac{2 \sinh(\phi) + 2 \epsilon_+}{2}.
\end{equation}
Here $|W|$ is the order of the Weyl group $W$, $r$ is the rank, “root” is the set of roots, and $\Delta(\text{adj})$ is the set of weights in the adjoint representation including zero weights with multiplicity $r$, all with respect to $H$.

For the $\mathcal{N} = (0,4)$ hypermultiplet in representation $R_{\text{hyp}}$ of $H \times F$, the one-loop determinant is
\begin{equation}
Z_{\text{hyp}} = \prod_{w \in \Delta(R_{\text{hyp}})} \frac{1}{2 \sinh(\pm w(\phi, m) + \epsilon_+)}
\end{equation}
where $\Delta(R)$ denotes the set of weights in a representation $R$, and $(\phi, m)$ is an element of the complexified Cartan subalgebra of $H \times F$.

For the $\mathcal{N} = (0,4)$ twisted hypermultiplet, we restrict to the case that it transforms in the adjoint representation of a simple Lie subgroup of $H$ and in the fundamental representation of $\text{SU}(2) \subseteq F$. The one-loop determinant is
\begin{equation}
Z_{\tilde{\text{hyp}}} = \prod_{w \in \Delta(\text{adj})} \frac{1}{2 \sinh(w(\phi) + m - \epsilon_+)}
\end{equation}

For the $\mathcal{N} = (0,4)$ short Fermi multiplet in representation $R_{\text{fer}}$ of $H \times F$, the one-loop determinant is given by\(^{34}\)
\begin{equation}
Z_{\text{fer}} = \prod_{w \in \Delta(R_{\text{fer}})} \frac{1}{2 \sinh(w(\phi, m))}
\end{equation}
The $\mathcal{N} = (0,4)$ long Fermi multiplet in representation $R_{\text{fer}}$ consists of one short Fermi multiplet in $R_{\text{fer}}$ and another in $\overline{R}_{\text{fer}}$.\(^{35}\)

C. On correlators involving $T_{\Lambda, 2V}$ in SO/USp SQCD

In sections 4.1 and 5.1, we considered the expectation values of the minimal ’t Hooft operator $T_{\Lambda}V$ in the $\mathcal{N} = 2$ SO/USp SQCD with the number $N_F$ of flavors for which the theory is conformal. This is $N_F = N - 2$ for $\text{SO}(N)$ and $N_F = N + 2$ for $\text{USp}(N)$. Here we study the expectation value of the ’t Hooft operator $T_{\Lambda, 2V}$ in the rank-2 antisymmetric representation of the Langlands dual of the gauge group. We relegated this case to the present appendix because there is a subtlety in the computation of their monopole screening contributions. The subtlety disappears when we consider SQCDs with less flavors and hence we present calculations involving $\langle T_{\Lambda, 2V} \rangle$ using an SQCD with less flavors.

\(^{34}\)Gauge invariance gives some restriction. For example $Z_{\text{fer}} = \prod_{j=1}^{N_F} 2 \sinh(\phi - m_j)$ is invariant under $\phi \to \phi + 2\pi$ (large gauge transformation) only for $N_F$ even. For $N_F$ odd, one can restore invariance by including the contribution $e^{ik\phi}$ from a Chern-Simons action with a half-odd integer level $k$.

\(^{35}\)In our previous paper [13] we actually used (B.9) here, not (A.10) of that paper, which contains a typo.
C.1 Correlators involving $T_{λ^2 V}$ in SO(N) SQCD

We start with monopole screening contributions involving $T_{λ^2 V}$ in the SO(N) SQCD.

C.1.1 $λ^2 V$

We first consider the expectation value of the 't Hooft operator $T_{λ^2 V}$ in the 4d $\mathcal{N} = 2$ SO(N) gauge theory with $N_F$ hypermultiplets in the vector representation, assuming that the operator $T_{λ^2 V}$ exists in the theory. We require the number of the flavors to satisfy $N_F \leq N - 2$ so that the theory is asymptotically free or superconformal. The magnetic charge of the operator $T_{λ^2 V}$ is $B = e_{n-1} + e_n$, which is the highest weight (in our convention) of the rank-2 anti-symmetric representation of the Langlands dual of the gauge group. (We recall the operator $N$ so that the theory is asymptotically free or superconformal. The magnetic charge of gauge theory and in the case of the SQCD they are given by $n = 1$.) The brane realization of the operator with the magnetic charge $B = e_{n-1} + e_n$ is shown in figure 4b.

The expectation value of this operator $T_{λ^2 V}$ takes the same form as (4.16), namely

$$\langle T_{λ^2 V} \rangle = \sum_{1 \leq i < j \leq n} \left( e^{b_i + b_j} + e^{-b_i - b_j} \right) Z_{ij}(a) + \sum_{1 \leq i < j \leq n} \left( e^{b_i - b_j} + e^{-b_i + b_j} \right) Z'_{ij}(a) + Z_{mono}(a).$$

(C.1)

The one-loop determinant parts $Z_{ij}(a)$, $Z'_{ij}(a)$ are different from those in 4d $\mathcal{N} = 2^*$ SO(N) gauge theory and in the case of the SQCD they are given by

$$Z_{ij}(a) = \left( \prod_{f=1}^{N_F} \frac{\Pi_{\frac{\pm a_i - m_f}{2} 2 \sinh \frac{\pm a_i - m_f}{2} 2 \sinh \frac{\pm a_i - m_f}{2} \Pi_{k \neq i,j} 2 \sinh \frac{\pm a_i + a_k + \epsilon + 2 \sinh \frac{\pm a_j + a_k + \epsilon}{2}}} {2 \sinh \frac{\pm (a_i + a_j)}{2} 2 \sinh \frac{\pm (a_i + a_j) + 2 \epsilon}{2} \Pi_{k \neq i,j} 2 \sinh \frac{\pm a_i + a_k + \epsilon + 2 \sinh \frac{\pm a_j + a_k + \epsilon}{2}}} \right)^{\frac{1}{2}}$$

(C.2)

and

$$Z'_{ij}(a) = \left( \prod_{f=1}^{N_F} \frac{\Pi_{\frac{\pm a_i - m_f}{2} 2 \sinh \frac{\pm a_i - m_f}{2} 2 \sinh \frac{\pm a_i - m_f}{2} \Pi_{k \neq i,j} 2 \sinh \frac{\pm a_i + a_k + \epsilon + 2 \sinh \frac{\pm a_j + a_k + \epsilon}{2}}} {2 \sinh \frac{\pm (a_i - a_j)}{2} 2 \sinh \frac{\pm (a_i - a_j) + 2 \epsilon}{2} \Pi_{k \neq i,j} 2 \sinh \frac{\pm a_i + a_k + \epsilon + 2 \sinh \frac{\pm a_j + a_k + \epsilon}{2}}} \right)^{\frac{1}{2}}$$

(C.3)

for the SO(2n) gauge theory, and

$$Z_{ij}(a) = \left( \prod_{f=1}^{N_F} \frac{\Pi_{\frac{\pm a_i - m_f}{2} 2 \sinh \frac{\pm a_i - m_f}{2} 2 \sinh \frac{\pm a_i - m_f}{2} \Pi_{\frac{\pm a_i + a_j + 2 \epsilon + 2 \sinh \frac{\pm a_i + a_j + 2 \epsilon}{2}}} {2 \sinh \frac{\pm a_i + a_j}{2} 2 \sinh \frac{\pm (a_i + a_j) + 2 \epsilon}{2} \Pi_{1 \leq k \neq j \leq n} 2 \sinh \frac{\pm a_i + a_k + \epsilon + 2 \sinh \frac{\pm a_j + a_k + \epsilon}{2}}} \right)^{\frac{1}{2}}$$

(C.4)

and

$$Z'_{ij}(a) = \left( \prod_{f=1}^{N_F} \frac{\Pi_{\frac{\pm a_i - m_f}{2} 2 \sinh \frac{\pm a_i - m_f}{2} 2 \sinh \frac{\pm a_i - m_f}{2} \Pi_{\frac{\pm a_i + a_j + 2 \epsilon + 2 \sinh \frac{\pm a_i + a_j + 2 \epsilon}{2}}} {2 \sinh \frac{\pm a_i + a_j}{2} 2 \sinh \frac{\pm (a_i + a_j) + 2 \epsilon}{2} \Pi_{1 \leq k \neq j \leq n} 2 \sinh \frac{\pm a_i + a_k + \epsilon + 2 \sinh \frac{\pm a_j + a_k + \epsilon}{2}}} \right)^{\frac{1}{2}}$$

(C.5)
Figure 27. (a): the brane configuration for the monopole screening contribution to the \(v = 0\) sector in \(T_{p,2V}\). (b): the corresponding quiver diagram.

for the SO\((2n+1)\) gauge theory. The last term \(Z_{\text{mono}}(a)\) in (C.1) is the monopole screening contribution corresponding to the zero weights in the rank-2 anti-symmetric representation.

Let us determine \(Z_{\text{mono}}(a)\). The brane configuration for monopole screening is shown in figure 27a. The vertical black dashed line represents an O4⁻-plane for \(N = 2n\), and an \(\widetilde{O}4^-\) plane for \(N = 2n + 1\). In addition there are \(N_F\) D6-branes, \(n\) D4-branes, and two D2-branes ending on a single NS5'-brane. The corresponding quiver diagram is given in figure 27b. Here we use the \(N = (0, 4)\) notation. If the number of the hypermultiplets is \(n + \frac{1}{2}\), it implies \(n\) hypermultiplets in the fundamental representation and a half-hypermultiplet in the fundamental representation. The supersymmetric index of the quiver theory is

\[
Z_{A^2V}(v = 0) = \frac{1}{2} \oint_{JK(\eta)} \frac{d\phi}{2\pi i} 2\sinh(\pm \phi) 2\sinh(\phi) 2\sinh(\pm \phi + \epsilon_+) \left( \prod_{i=1}^{N_F} 2\sinh(\pm \phi - m_i) \right) \frac{\prod_{i=1}^{n} 2\sinh(\pm \phi + \epsilon_+)}{\prod_{i=1}^{n} 2\sinh(\pm \phi + \epsilon_+)}.
\]

(C.6)

for \(N = 2n\) and

\[
Z_{A^2V}(v = 0) = \frac{1}{2} \oint_{JK(\eta)} \frac{d\phi}{2\pi i} 2\sinh(\pm \phi) 2\sinh(\phi + \epsilon_+) 2\sinh(\pm \phi + \epsilon_+) \left( \prod_{i=1}^{N_F} 2\sinh(\pm \phi - m_i) \right) \frac{2\sinh(\pm \phi + \epsilon_+)}{\prod_{i=1}^{n} 2\sinh(\pm \phi + \epsilon_+)}.
\]

(C.7)

for \(N = 2n + 1\).

In the case of \(N_F = N - 2\) where the theory becomes superconformal, the integrand of (C.6) and (C.7) has a higher order pole at the infinities \(\phi = \pm \infty\). A higher order pole in the supersymmetric index of an SQM also appears in the computation of the instanton partition function of a 5d gauge theory with a large number of flavors or a 5d SU\((N)\) gauge theory with a large Chern-Simons level. For example, an SQM for the instanton partition function of the SU\((3)\) gauge theory with \(N_F\) flavors with the Chern-Simons level \(\kappa = 5 - \frac{N_F}{2}\) has been considered in [72]. The integrand of the supersymmetric index of the corresponding ADHM quantum mechanics has a higher order pole and the computation of the supersymmetric index was carried out by adding pseudo hypermultiplets which make the higher order pole disappear. Since the integrand (C.6) and (C.7) has a higher order...
pole at the infinites, we might need a similar technique to compute the integral. Here instead we will use less number of flavors such that (C.6) and (C.7) do not have a pole at the infinites. Namely we assume $N_F \leq N - 5$.

In the cases where $N_F \leq N - 5$, we can evaluate the integral (C.6) and (C.7) in a usual way. Namely we take the contributions from the poles $\phi = \pm a_i - \epsilon_+$ for $\eta > 0$ or $\phi = \pm a_i + \epsilon_+$ for $\eta < 0$. In this case the JK residue of the integral for the both sets of the poles yields the same result regardless of the sign of $\eta$, and they are given by

$$Z_{\wedge^2 V}(v = 0) = \sum_{i=1}^{n} \left( \frac{2 \sinh(-a_i - \epsilon_+) \sinh(-a_i + 2\epsilon_+) \prod_{j=1}^{N_F} 2 \sinh \left( \frac{a_j - m_f - \epsilon_+}{2} \right) \prod_{k \neq i \leq n} 2 \sinh \left( \frac{a_k + a_i + 2\epsilon_+}{2} \right)}{2 \sinh \left( \frac{a_i + a_k + 2\epsilon_+}{2} \right) \prod_{k \neq i \leq n} 2 \sinh \left( \frac{a_k + a_i + 2\epsilon_+}{2} \right)} \right).$$

For $N = 2n$ and

$$Z_{\wedge^2 V}(v = 0) = \sum_{i=1}^{n} \left( \frac{2 \sinh(a_i - \epsilon_+) \sinh(a_i + 2\epsilon_+) \prod_{j=1}^{N_F} 2 \sinh \left( \frac{a_j - m_f - \epsilon_+}{2} \right) \prod_{k \neq i \leq n} 2 \sinh \left( \frac{a_k + a_i + 2\epsilon_+}{2} \right)}{2 \sinh \left( \frac{a_i + a_k + 2\epsilon_+}{2} \right) \prod_{k \neq i \leq n} 2 \sinh \left( \frac{a_k + a_i + 2\epsilon_+}{2} \right)} \right).$$

For $N = 2n + 1$. In this case there is no extra term, which we checked for $N = 5, 6, 7, 8, 9, 10, 11, 12$, and $Z_{\text{mono}}(a)$ in (C.1) is given by (C.8) or (C.9) for $SO(2n)$ or for $SO(2n + 1)$ respectively when $N_F \leq N - 5$.

### C.1.2 $\wedge^2 V \times V$

Let us then consider the expectation value of a product involving $T_{\wedge^2 V}$. The simple case is the product between $T_{\wedge^2 V}$ and $T_V$ which we considered in section 4.1. Since we consider the Moyal product of different operators we may need to be careful of the order of the product. Here we do not consider all the screening sectors but focus on the most screened sector which is characterized by $v = e_i$. The $v = e_i$ sector in the Moyal product $\langle T_{\wedge^2 V} \rangle \ast \langle T_V \rangle$ is given by

$$\langle T_{\wedge^2 V} \rangle \ast \langle T_V \rangle \bigg|_{v = e_i} = e^{hi} \sum_{1 \leq j \neq i \leq n} \left( Z_{ij}(a - \epsilon_+ e_j) Z_j(a - \epsilon_+ (e_i + e_j)) \right)$$

$$+ Z'_{ij}(a + \epsilon_+ e_j) Z_j(a - \epsilon_+ (e_i - e_j)) \bigg) + e^{hi} Z_{\text{mono}}(a + \epsilon_+ e_i) Z_i(a)$$

$$=: e^{hi} Z_{1\text{-loop}}(v = e_i) Z_{\wedge^2 V \times V}(v = e_i).$$
Figure 28. (a): the brane configuration corresponding to the monopole screening sector \( v = +e_N \) for the product 't Hooft operator \( T_V \wedge T_V \). (b): a brane configuration obtained by moving the top NS5'-brane to the left. (c): a brane configuration obtained by moving the bottom NS5'-brane to the left.

Figure 29. (a): the quiver diagram read off from figure 28b. (b): the quiver diagram read off from figure 28c.

One the other hand the sector \( v = e_i \) in the Moyal product in the order \( \langle T_V \rangle \ast \langle T_V \wedge T_V \rangle \) is

\[
\left. \langle T_V \rangle \ast \langle T_V \wedge T_V \rangle \right|_{v = e_i} = e^{b_i} \sum_{1 \leq j \neq i \leq n} \left( Z_j(a + \epsilon_+(e_i + e_j))Z_{ij}(a + \epsilon_+ e_j) + Z_j(a + \epsilon_+(e_i - e_j))Z'_{ij}(a - \epsilon_+ e_j) \right) + e^{b_i} Z_i(a)Z_{\text{mono}}(a - \epsilon_+ e_i)
\]

\[
=: e^{b_i} Z_{1\text{-loop}}(v = e_i)Z^V_{\text{mono}}(v = e_i).
\]

We wish to compare the quantities \( Z^{V \wedge V}_{\text{mono}}(v = e_i) \) and \( Z^V_{\text{mono}}(v = e_i) \) in (C.10) and (C.11) with the supersymmetric indices of the corresponding SQMs. To read off the SQMs which describe monopole screening we use brane configurations shown in figure 28. Two ways of moving the NS5'-branes via the Hanany-Witten transition yield two different SQMs that compute monopole screening contributions. The SQMs obtained from the configurations in figures 28b and 28b are depicted in figures 29a and 29b, respectively. Since the configurations are related by Hanany-Witten transitions, the two SQMs are dual to each other and possess identical indices. It is thus enough to consider one of the SQMs.
Let us focus on the SQM specified by the quiver in figure 29a. Its index is given by

\[
Z(v = e_i, \zeta) = \frac{1}{2} \oint_{JK(\zeta)} \frac{d\phi_1}{2\pi i} \frac{d\phi_2}{2\pi i} 2\sinh(\pm \phi_1) \times \frac{(2\sinh\epsilon_+)^2 2\sinh(\pm \phi_1 + \epsilon_+) \prod_{j=1}^{N_F} 2\sinh \frac{\pm \phi_1 - m_j}{2}}{2\sinh \frac{\pm \phi_1 + \epsilon_+}{2} \prod_{1 \leq j \neq i \leq n} 2\sinh \frac{\pm \phi_1 \pm \phi_2 + \epsilon_+}{2}} \frac{1}{2\sinh \frac{\pm \phi_1 \pm \phi_2 + \epsilon_+}{2} 2\sinh \frac{2\sinh(\pm \phi_2 + \epsilon_+)}{2}}
\]  
(C.12)

for \( N = 2n \) and

\[
Z(v = e_i, \zeta) = \frac{1}{2} \oint_{JK(\zeta)} \frac{d\phi_1}{2\pi i} \frac{d\phi_2}{2\pi i} 2\sinh(\pm \phi_1) \times \frac{(2\sinh\epsilon_+)^2 2\sinh(\pm \phi_1 + \epsilon_+) \prod_{j=1}^{N_F} 2\sinh \frac{\pm \phi_1 - m_j}{2}}{2\sinh \frac{\pm \phi_1 + \epsilon_+}{2} \prod_{1 \leq j \neq i \leq n} 2\sinh \frac{\pm \phi_1 \pm \phi_2 + \epsilon_+}{2}} \frac{1}{2\sinh \frac{\pm \phi_1 \pm \phi_2 + \epsilon_+}{2} 2\sinh \frac{2\sinh(\pm \phi_2 + \epsilon_+)}{2}}
\]  
(C.13)

for \( N = 2n + 1 \). We can explicitly perform the JK residue computations for (C.12) and (C.13) with the JK parameter \( \eta = (\delta, \zeta) \) where \( |\delta| \ll |\zeta| \). Comparing the results with the monopole screening contributions (C.10) and (C.11) yields the relations

\[
Z_{\text{mono}}^{\wedge^2 V \times V}(v = e_i) = Z(v = e_i, \zeta < 0), \quad Z_{\text{mono}}^{V \times \wedge^2 V}(v = e_i) = Z(v = e_i, \zeta > 0). \quad \text{(C.14)}
\]

We also checked that \( Z(v = e_i, \zeta > 0) = Z(v = e_i, \zeta < 0) \) for \( (N, N_F) = (8, 3), (7, 2) \).

**C.2 Correlators involving** \( T_{\lambda^2 V} \) **in** \( \text{USp}(N) \) **SQCD**

We next consider monopole screening contributions involving \( T_{\lambda^2 V} \) in an \( \text{USp}(N) \) SQCD.

**C.2.1 \( \wedge^2 V \)**

The next case is the expectation value of the 't Hooft operator \( T_{\lambda^2 V} \) in the 4d \( \mathcal{N} = 2 \) \( \text{USp}(2n) \) gauge theory with \( N_F \) hypermultiplets in the vector representation, assuming the operator \( T_{\lambda^2 V} \) exists in the theory. The number of the flavors satisfy \( N_F \leq 2n + 2 \) for focusing on asymptotic free or superconformal field theories. \( \wedge^2 V \) represents the rank-2 anti-symmetric representation of the Langlands dual group which is \( \text{SO}(2n + 1) \), which is the adjoint representation of \( \text{SO}(2n + 1) \). The expectation value of the 't Hooft operator \( T_{\lambda^2 V} \) takes the same form as (5.21), namely

\[
\langle T_{\lambda^2 V} \rangle = \sum_{1 \leq i < j \leq n} \left( e^{b_i + b_j} + e^{-b_i - b_j} \right) Z_{ij}(a) + \sum_{1 \leq i < j \leq n} \left( e^{b_i - b_j} + e^{-b_i + b_j} \right) Z'_{ij}(a)
\]

\[
+ \sum_{i=1}^{n} \left( e^{b_i} + e^{-b_i} \right) Z_i(a) Z'_{\text{mono},i}(a) + Z''_{\text{mono}}(a),
\]

where \( Z_i \) is defined in (5.2), \( Z_{ij} \) in (5.8), and \( Z'_{ij} \) by

\[
Z'_{ij}(a) = \left( \prod_{1 \leq k \neq i, k \neq j \leq n} 2\sinh \frac{\pm a_i - a_j + 2\epsilon_+}{2} \prod_{1 \leq k \neq i, k \neq j \leq n} 2\sinh \frac{\pm a_i \pm a_j + \epsilon_+}{2} \right) \frac{1}{2\sinh(\pm a_i) 2\sinh(\pm a_j) 2\sinh(\pm a_i + \epsilon_+) 2\sinh(\pm a_j + \epsilon_+)} \left( \prod_{1 \leq k \neq i, k \neq j \leq n} 2\sinh \frac{\pm a_i - a_j + 2\epsilon_+}{2} \prod_{1 \leq k \neq i, k \neq j \leq n} 2\sinh \frac{\pm a_i \pm a_j + \epsilon_+}{2} \right)^{\frac{1}{2}}.
\]  
(C.16)
As can be seen from the explicit form of (C.15), we have two types of the monopole screening contributions $Z'_{\text{mono}, i}(a)$ and $Z''_{\text{mono}}(a)$. The SQM which describes the contribution $Z'_{\text{mono}, i}(a)$ can be read off from the brane configuration in figure 30a, which leads to the quiver in figure 30b. The computation of the supersymmetric index of the quiver in figure 30b is similar to the one for the quiver theory in figure 19b. Since the computation is parallel to (5.5), we here simply write the final result, which is

$$Z'_{\chi^2 V_j}(\mathbf{v} = e_i) = \frac{1}{2} \left( \prod_{\ell=1}^{N_F} \frac{2 \sinh \frac{m_f}{T}}{\prod_{1 \leq j \neq i \leq n} 2 \sinh \frac{2a_{j+} + \epsilon_j}{2}} + \prod_{\ell=1}^{N_F} \frac{2 \cosh \frac{m_f}{T}}{\prod_{1 \leq j \neq i \leq n} 2 \cosh \frac{2a_{j+} + \epsilon_j}{2}} \right).$$  

(C.17)

In this case there is no extra term, and $Z'_{\text{mono}, i}(a)$ in (C.15) is given by (C.17).

The other monopole screening contribution $Z''_{\text{mono}}(a)$ corresponds to the zero weights of the adjoint representation of $SO(2n + 1)$ and the brane configuration in figure 31a for the sector gives rise to the quiver theory depicted in figure 31b. Similar to the $O(1)$ case in section 5.1.1, the $O(2)$ integral can be split into two contributions $O(2)_+$ and $O(2)_-$. The
The integrand in (C.18) also has a higher order pole at the infinities \( \phi = \pm \infty \) in the superconformal case with \( N_F = 2n + 2 \). In order to avoid the poles at the infinities, we choose \( N_F \leq 2n - 1 \). Then the integral of (C.18) can be evaluated by taking the sum of the contributions from the poles \( \phi = \pm a_i - \epsilon_+ \) or \( \phi = \pm a_i + \epsilon_+ \) and the both give

\[
Z''_{\Lambda^2 V^+}(v = 0) = \sum_{i=1}^{n} \left( \prod_{f=1}^{N_F} 2 \sinh(a_i) 2 \sinh(-a_i + \epsilon_+) \prod_{1 \leq j \neq i \leq n} 2 \sinh(\frac{a_i+\epsilon_+}{2}) \sinh(\frac{a_i-a_j+2\epsilon_+}{2}) \right) \left( \prod_{f=1}^{N_F} 2 \sinh(a_i) 2 \sinh(-a_i - \epsilon_+) \prod_{1 \leq j \neq i \leq n} 2 \sinh(\frac{a_i+\epsilon_+}{2}) \sinh(\frac{a_i-a_j-2\epsilon_+}{2}) \right) .
\] (C.19)

On the other hand, the contribution from \( O(2)_- \) is

\[
Z''_{\Lambda^2 V^-}(v = 0) = \frac{2 \cos(\epsilon_+)}{2 \prod_{f=1}^{N_F} 2 \sinh(a_i + \epsilon_+)} .
\] (C.20)

Then the supersymmetric index of the quiver in figure 31b is given by the average of (C.19) and (C.20), namely

\[
Z''_{\Lambda^2 V}(v = 0) = \frac{1}{2} (Z''_{\Lambda^2 V^+}(v = 0) + Z''_{\Lambda^2 V^-}(v = 0)) .
\] (C.21)

Since the monopole screening contribution in \( \langle T_V \rangle \) of the theory does not have an extra term, we can apply the extra term prescription to the monopole screening contribution \( Z''_{\text{mono}}(a) \) in \( \langle T_{\Lambda^2 V} \rangle \). It turns out that in this case also there is no extra term, which we checked for \( n = 1, 2, 3, 4, 5 \), and \( Z''_{\text{mono}}(a) \) in (C.15) is given by (C.21) for \( N_F \leq 2n - 1 \).

### C.2.2 \( \Lambda^2 V \times V \)

It is also possible to consider the expectation value of the product of \( T_{\Lambda^2 V} \) and \( T_V \). The expectation value may depend on the order of the operators generally. Here we also focus on the screening sector characterized by \( v = e_i \) and \( v = 0 \).

\( v = e_i \). The monopole screening contribution of \( \langle T_{\Lambda^2 V} \rangle \ast \langle T_V \rangle \) in the sector \( v = e_i \) is given by

\[
\langle T_{\Lambda^2 V} \rangle \ast \langle T_V \rangle \big|_{v=e_i} = e^{bi} Z_i(a) Z_{\text{mono}}(a - \epsilon_+ e_i) Z_{\text{mono}}(a + \epsilon_+ e_i) \left( Z_{ij}(a + \epsilon_+ (e_i + e_j)) + Z_{ij}(a + \epsilon_+ (e_j - e_i)) \right) + e^{bi} \sum_{1 \leq j \neq i \leq n} \left( Z_{ij}(a + \epsilon_+ (-e_j)) Z_{ij}(a - \epsilon_+ (e_i + e_j)) \right) + Z_{1\text{loop}}(v = e_i) Z_{\text{mono}}^{\Lambda^2 V \times V}(v = e_i) .
\] (C.22)

\( \text{See footnote } 18. \)
Similarly the monopole screening contribution of $\langle T_V \rangle \ast \langle T_{\lambda^2 V} \rangle$ in the sector $v = e_i$ is given by

$$\langle T_V \rangle \ast \langle T_{\lambda^2 V} \rangle|_{v=e_i} = e^{b_i} \text{Z}_{\text{mono}}(a+\epsilon_+e_i)Z_i(a)Z_{\text{mono},i}(a) + e^{b_i} Z_i(a)Z''_{\text{mono}}(a-\epsilon_+e_i) + e^{b_i} \sum_{1 \leq j \neq i \leq n} Z_{ij}(a+\epsilon_+(e_i+e_j))Z_{ij}(a-\epsilon_+(-e_j)) + Z_{ij}(a+\epsilon_+(e_i-e_j))Z''_{ij}(a-\epsilon_+e_j)$$

$$= :e^{b_i} Z_{1\text{-loop}}(v = e_i)Z_{V \times \lambda^2 V}^{\text{mono}}(v = e_i).$$

We compute the monopole screening contributions $Z_{\text{mono}}^{V \times \lambda^2 V}(v = e_i)$ and $Z_{\text{mono}}^{V \times \lambda^2 V}(v = e_i)$ from the supersymmetric index of the corresponding SQM. The brane configurations for these sectors with $i = N$ are those in figures 28a and 28b, where we take the O4-plane to be of the type O4$^+$. These configurations yield the two quiver theories depicted in figure 32. However the brane configurations yielding the quiver theories in figure 32 are related by moving D-branes and hence they are dual to each other. We will use the simpler quiver theory in figure 32a to compute the supersymmetric index.

The supersymmetric index consists of contributions from two sectors, O(2)$_+ - U(1)$ and O(2)$_- - U(1)$. The contribution from the O(2)$_+ - U(1)$ sector is given by

$$Z_+(v = e_i, \zeta) = \int_{JK(\zeta)} \frac{d\phi_1}{2\pi i} \frac{d\phi_2}{2\pi i} \frac{(2\sinh(\epsilon_+))^{2n+2} \prod_{m=1}^{2n+2} \sinh^{\frac{\phi_1 - \phi_2 + \phi_+}{2}} \sinh^{\frac{\phi_1 + \phi_2 + \phi_+}{2}} \prod_{1 \leq j \neq i \leq n} \sinh^{\pm \phi_1 \pm \phi_2 + \epsilon_+} \sinh^{\pm \phi_1 \pm \phi_2 + \epsilon_+}}{2} \sinh^{\pm \phi_1 \pm \phi_2 + \epsilon_+}$$

where $\zeta$ is the FI parameter for the U(1) gauge group. The contribution from the O(2)$_- - U(1)$ sector is

$$Z_-(v = e_i, \zeta) = \int_{JK(\zeta)} \frac{d\phi_2}{2\pi i} 2 \cos(\epsilon_+) \prod_{m=1}^{2n+2} \sinh(\epsilon_+) \prod_{1 \leq j \neq i \leq n} \sinh(\pm \phi_2 + \epsilon_+) \sinh(\pm a_j + \epsilon_+)) \sinh^2 \frac{\phi_2 - \phi_1 + \epsilon_+}{2}$$

The supersymmetric index is then given by

$$Z(v = e_i, \zeta) = \frac{1}{2}(Z_+(v = e_i, \zeta) + Z_-(v = e_i, \zeta)).$$
We compare (C.26) with (C.22), (C.23) calculated from the Moyal product. We checked the following equality explicitly for \( n = 2 \) and \( N_F = 3 \), and believe that it holds generally:

\[
Z(v = e_i, \zeta) = Z^{V \times V}_{\text{mono}}(v = e_i) = Z_{\text{mono}}^{V \times V}(v = e_i).
\]  

(C.27)

for both \( \zeta > 0 \) and \( \zeta < 0 \).

\( v = 0 \). The \( v = 0 \) sector in the Moyal product of the form \( \langle T_{\lambda^2 V} \rangle \ast \langle T_V \rangle \) is given by

\[
\langle T_{\lambda^2 V} \rangle \ast \langle T_V \rangle \bigg|_{v=0} = \sum_{i=1}^{n} \left( Z_i(a - \epsilon_i + e_i)^2 Z'_{\text{mono},i}(a - \epsilon_i + e_i) + Z_i(a + \epsilon_i + e_i)^2 Z'_{\text{mono},i}(a + \epsilon_i + e_i) \right) + Z_{\text{mono}}(a) Z''_{\text{mono}}(a)
\]

:= \( Z^{V \times V}_{\text{mono}}(v = 0) \),

(C.28)

The \( v = 0 \) sector in the Moyal product for the other order yields

\[
\langle T_V \rangle \ast \langle T_{\lambda^2 V} \rangle \bigg|_{v=0} = \sum_{i=1}^{n} \left( Z_i(a + \epsilon_i + e_i)^2 Z'_{\text{mono},i}(a + \epsilon_i + e_i) + Z_i(a + \epsilon_i + e_i)^2 Z'_{\text{mono},i}(a + \epsilon_i + e_i) \right) + Z_{\text{mono}}(a) Z''_{\text{mono}}(a)
\]

:= \( Z^{V \times V}_{\text{mono}}(v = 0) \).

(C.29)

The sector arise from \( v = (e_i) + (-e_i), (-e_i) + (e_i), 0 + 0 \). Note that from the explicit form of (C.28) and (C.29) the both contributions give the same result in this sector.

Let us compare \( Z^{V \times V}_{\text{mono}}(v = 0) \) in (C.29) with the supersymmetric index of the corresponding SQM. The brane configuration shown in figure 33a gives the quiver depicted in figure 33b. The supersymmetric index of the quiver theory can be computed in a similar manner. The contribution consists of contributions from two components, \( O(3)_+ - U(1) \).
and $O(3) - U(1)$. The contribution from $O(3) - U(1)$ is given by

$$Z_+(v = 0, \zeta) = \frac{1}{2} \oint \frac{d\phi_1}{2\pi i} \frac{d\phi_2}{2\pi i} 2 \sinh \frac{\pm \phi_1}{2} 2 \sinh \frac{\pm \phi_1 + 2\epsilon_+}{2} (2 \sinh \epsilon_+)^2$$

$$\times \left( \prod_{f=1}^{N_F} 2 \sinh \frac{\pm \phi_1 - m_f}{2} 2 \sinh \frac{m_f}{2} \right) \left( \prod_{i=1}^{n} \frac{2 \sinh \frac{\pm \phi_1 \pm a_i + \epsilon_+}{2} 2 \sinh \frac{\pm \phi_1 + \epsilon_+}{2}}{2 \sinh \frac{\pm \phi_1 + \epsilon_+}{2} 2 \sinh \frac{\pm \phi_2 + \epsilon_+}{2}} \right),$$

and the contribution from $O(3) - U(1)$ is given by

$$Z_-(v = 0, \zeta) = \oint \frac{d\phi_1}{2\pi i} \frac{d\phi_2}{2\pi i} 2 \cosh \frac{\pm \phi_1}{2} 2 \cosh \frac{\pm \phi_1 + 2\epsilon_+}{2} (2 \sinh \epsilon_+)^2$$

$$\times \left( \prod_{f=1}^{N_F} 2 \sinh \frac{\pm \phi_1 + m_f}{2} 2 \cosh \frac{m_f}{2} \right) \left( \prod_{i=1}^{n} \frac{2 \sinh \frac{\pm \phi_1 \pm a_i + \epsilon_+}{2} 2 \sinh \frac{\pm \phi_1 + \epsilon_+}{2}}{2 \sinh \frac{\pm \phi_1 + \epsilon_+}{2} 2 \sinh \frac{\pm \phi_2 + \epsilon_+}{2}} \right).$$

Then the supersymmetric index is given by

$$Z(v = 0, \zeta) = \frac{1}{2} (Z_+(v = 0, \zeta) + Z_-(v = 0, \zeta)).$$

We can then compare the supersymmetric index (C.32) with the Moyal product (C.28) or (C.29). For the explicit evaluation of the supersymmetric index (C.32), we use the JK parameter $\eta = (\delta, \zeta)$ with $|\delta| \ll |\zeta|$. Then we find

$$Z(v = 0, \zeta) = Z_{\text{mono}}^{V \times V}(v = 0) = Z_{\text{mono}}^{V \times V}(v = 0),$$

for $\zeta > 0$ and $\zeta < 0$, which we checked for $n = 2$ and $N_F = 3$.

### C.3 Naive extension to superconformal cases

In superconformal cases for SO($N$) gauge theories and USp($2n$) gauge theories, we mentioned the subtlety of the presence of higher order poles in (C.6), (C.7) and (C.18). When we chose the cases of $N_F \leq N - 5$ for the SO($N$) SQCD and of $N_f \leq 2n - 1$ for the USp($2n$) SQCD, where there are no poles at infinities, the monopole screening contributions in $\langle T_{\lambda^2 V} \rangle$ become (C.8), (C.9) and (C.19) respectively. Here we consider consequences when we simply set the $N_F$ to be the number of flavors when the theories become conformal in (C.8), (C.9), (C.17), (C.19) and (C.20).

For the SO($N$) gauge theory, the correlator $\langle T_{\lambda^2 V} \cdot T_V \rangle$ and $\langle T_V \cdot T_{\lambda^2 V} \rangle$ has a monopole screening contribution in the $v = e_1$ sector and it is given by (C.12) for $N = 2n$ and (C.13) for $N = 2n + 1$ when $N_F \leq N - 5$. Again let us set $N_F = N - 2$ and take the same poles of the integral (C.12) and (C.13) as those which we used in the less flavor cases, and then compare the sum of the residues of the poles with the result from the corresponding part of the Moyal product.

Let us denote the sets of poles by $S_1^{SO(8)}, S_1^{SO(8)}$, $S_2^{SO(8)}, S_2^{SO(8)}$ which are respectively related to the poles in (C.12) from the JK parameter $\eta$ with $(\delta > 0, \zeta < 0)$, $(\delta < 0, \zeta < 0)$,
equal to that from the pole sets computing the residues of (C.24) and (C.25) in the case of by \((\delta > 0)\) that from the JK parameter \(\eta\) are respectively related to the poles from the JK parameter \(S_1^{SO(8)}\), \(S_1^{\ell r^{SO(8)}}\), \(S_2^{SO(8)}\) and \(S_2^{\ell r^{SO(8)}}\) for \((N, N_F) = (8, 6)\) gives the same result and it agrees with \(Z_{\text{mono}}^{V \times V}(v = e_4)\) in (C.11) with \((N, N_F) = (8, 6)\). In this case the result depends on the order, namely \(Z_{\text{mono}}^{V \times V}(v = e_4) \neq Z_{\text{mono}}^{V \times V}(v = e_4)\). Similarly we denote the sets of poles of (C.13) by \(S_1^{SO(7)}\), \(S_1^{\ell r^{SO(7)}}\), \(S_2^{SO(7)}\) and \(S_2^{\ell r^{SO(7)}}\) which are respectively related to the poles from the JK parameter \(\eta\) with \((\delta > 0, \zeta < 0)\), \((\delta < 0, \zeta < 0)\), \((\delta > 0, \zeta > 0)\) and \((\delta < 0, \zeta > 0)\) in the case of \((N, N_F) = (7, 2)\). The sum of the residues of (C.13) from the poles of \(S_1^{SO(7)}\) for \((N, N_F) = (7, 5)\) in the sector \(v = e_3\) is the same as the sum of the residues from the poles of \(S_1^{SO(7)}\) with the same \(N\) and \(N_F\) and the result agrees with \(Z_{\text{mono}}^{V \times V}(v = e_3)\) in (C.10) with \((N, N_F) = (7, 5)\). On the other hand, the sum of the residues from the poles of \(S_2^{SO(7)}\) and that from \(S_2^{\ell r^{SO(7)}}\) for \((N, N_F) = (7, 5)\) in the sector \(v = e_3\) give the same result which agrees with \(Z_{\text{mono}}^{V \times V}(v = e_3)\) in (C.11) with \((N, N_F) = (7, 5)\). In this case again we observe \(Z_{\text{mono}}^{V \times V}(v = e_3) \neq Z_{\text{mono}}^{V \times V}(v = e_3)\).

We then move on to monopole screening contributions of the same type of the correlator in the \(USp(2n)\) SQCD. The monopole screening contribution in the \(v = e_1\) sector in the case of \(N_F \leq 2n - 1\) is given by (C.26) based on (C.24) and (C.25) and the monopole screening contribution in the \(v = 0\) sector in the case of \(N_F \leq 2n - 1\) is (C.32) based on (C.30) and (C.31). Here we consider the sum of the residues using the same poles in the less flavor cases for the number of flavors \(N_F = 2n + 2\) and compare the result with that from the Moyal product.

We start from the monopole screening contribution in the \(v = e_1\) sector. Let the sets of poles of (C.24) from the JK parameter \(\eta\) with \((\delta > 0, \zeta < 0)\), \((\delta < 0, \zeta < 0)\), \((\delta > 0, \zeta > 0)\) and \((\delta < 0, \zeta > 0)\) be \(S_1^{USp(4)}\), \(S_1^{USp(4)}\), \(S_2^{USp(4)}\) and \(S_2^{USp(4)}\) respectively for \((n, N_F) = (2, 3)\). Also we denote the sets of poles of (C.25) from the JK parameter \(\zeta\) with \(\zeta < 0\) and \(\zeta > 0\) by \(S_1^{USp(4)}\) and \(S_2^{USp(4)}\) respectively for \((n, N_F) = (2, 3)\). Then we use these poles for computing the residues of (C.24) and (C.25) in the case of \((n, N_F) = (2, 6)\) and take the average like (C.26). The contribution from the sets \(S_1^{USp(4)}\) and \(S_1^{USp(4)}\) is the same as that from the pole sets \(S_1^{USp(4)}\) and \(S_1^{USp(4)}\), and the contribution in the sector \(v = e_1\) is equal to \(Z_{\text{mono}}^{V \times V}(v = e_1)\) with \((n, N_F) = (2, 6)\). Similarly the contribution from the sets
$S_{2+}^{USp(4)}$ and $S_{2-}^{USp(4)}$ is the same as that from the pole sets $S_{2+}^{USp(4)}$ and $S_{2-}^{USp(4)}$, and the contribution in the sector $v = e_1$ is equal to $Z_{\text{mono}}^{V \times A^N}(v = e_1)$ with $(n, N_F) = (2, 6)$. In this case the Moyal product depends on the order and $Z_{\text{mono}}^{V \times A^N}(v = e_1) \neq Z_{\text{mono}}^{V \times A^N}(v = e_1)$.

Finally we consider the monopole screening contribution in the $v = 0$ sector. We denote the sets of poles of (C.30) from the JK parameter $\eta$ with $(\delta > 0, \zeta < 0)$, $(\delta < 0, \zeta < 0)$, $(\delta > 0, \zeta > 0)$ and $(\delta < 0, \zeta > 0)$ by $S_{2+}^{USp(4)}, S_{v+}^{USp(4)}, S_{2-}^{USp(4)}$ and $S_{2+}^{USp(4)}$ respectively for $(n, N_F) = (2, 3)$. Also let the sets of poles of (C.31) from the JK parameter $\eta$ with $(\delta > 0, \zeta < 0)$, $(\delta < 0, \zeta < 0)$, $(\delta > 0, \zeta > 0)$ and $(\delta < 0, \zeta > 0)$ be $S_{1+}^{USp(4)}, S_{1-}^{USp(4)}, S_{2-}^{USp(4)}$ and $S_{2+}^{USp(4)}$ respectively for $(n, N_F) = (2, 3)$. We then evaluate the integral of (C.30) and (C.31) with $(n, N_F) = (2, 6)$ using the poles and take the average like (C.32). In this case the contributions from the pairs of the sets $(S_{2+}^{USp(4)}, S_{1+}^{USp(4)}), (S_{v+}^{USp(4)}, S_{1-}^{USp(4)}), (S_{2+}^{USp(4)}, S_{2-}^{USp(4)}), (S_{2+}^{USp(4)}, S_{2-}^{USp(4)})$ all give the same result and it agrees with $Z_{\text{mono}}^{V \times A^N}(v = 0) = Z_{\text{mono}}^{V \times A^N}(v = 0)$ for $(n, N_F) = (2, 6)$.
