Abstract

We extend the formalism introduced in the paper hep-th/0209050 to compute correlation functions in the AdS/CFT correspondence. We show how the on-shell action of a scalar field in a compactification of AdS space can be obtained by flowing in the space of (non-local) theories with different sizes of the extra-dimension. Our method is relevant in particular for holographic computations in the Randall-Sundrum scenario with one or two branes and it allows the inclusion of brane-localized actions in a systematic way. The method can also be generalized to other backgrounds and does not rely on explicit knowledge of the solutions of the wave-equations.

1 Introduction

The full dynamical content of the AdS/CFT correspondence [1] (for a review [2]) can be summarized by an equivalence between two path integrals [3], [4]:

\[ Z[\phi_0] = \int_{\phi \sim \phi_0} D\phi \exp(-S[\phi]) = \left\langle \exp \int_{M_d} d^d x \phi_0 O \right\rangle_{CFT} \tag{1.1} \]

Here \( \phi \) represents the fields propagating on Anti-de Sitter space (AdS) and \( O \) are the dual gauge invariant operators in the Conformal Field Theory (CFT). \( Z[\phi_0] \) is the partition function on (Euclidian) AdS\(_{d+1}\), computed with the boundary condition that the field \( \phi \) approaches \( \phi_0 \) at the boundary of AdS. The right-hand side of (1.1) is the generating functional of the correlation functions of the dual CFT living on the boundary \( M_d \) of AdS\(_{d+1}\). In the limit where classical field theory is a good description of the physics on AdS (corresponding to the large \( N \) limit and large \( \text{\textquoteleft\textquoteleft \text{t} \text{\textquoteleft\textquoteleft Hooft parameter on the CFT side)\textquoteleft\textquoteleft\textnoquotesingle},\textnoquotesingle}\text\textquoteleft\textquoteleft}, \]}

\[ Z[\phi_0] = \exp(-S_{cl}[\phi_0]) \tag{1.2} \]

where \( S_{cl}[\phi_0] \) is the on-shell value of the classical action for fields that satisfy the condition \( \phi \sim \phi_0 \) at the boundary of AdS. In order to compute \( S_{cl}[\phi_0] \) typically one first reconstructs, using the classical equations of motion, the on-shell value of \( \phi \) with the required boundary behavior and then substitute in the action. This can be done iteratively using bulk-to-boundary and bulk-to-bulk propagators.

The goal of this paper will be to show how to compute \( S_{cl}[\phi_0] \) using the method of brane running. In principle, no explicit knowledge of bulk-to-boundary an bulk-to-bulk propagators is required. This approach was originally proposed in [5] and extended in [6] to gauge fields and gravity, to compute effective field theories of a brane-localized observer in the Randall-Sundrum scenario with two branes (RS1) [7]. As in that paper, we will consider the compactification of AdS on an orbifold \( S_1/\mathbb{Z}_2 \) with fixed points at \( z_{UV} \) (the ultraviolet brane) and at \( z_{IR} \) (the infrared brane), where \( z \) is the radial coordinate of AdS. In the context of the full AdS/CFT correspondence, this geometry should be simply regarded as a regularization: the \( UV \) brane modifies AdS near the boundary and the \( IR \) brane cuts the space in the direction of the horizon. In the RS1 scenario instead, two physical branes placed at the fixed points end the space. In [5] the authors were interested in computing effective theories of an observer localized on the \( IR \) brane, while here we will use the brane running method to compute the on-shell action as a function of the fields at \( z_{UV} \).

The basic idea is that the dependence of the on-shell value of the action on the fields at \( z_{UV} \) can be obtained integrating out bulk degrees of freedom. Specifically, we consider theories with different locations of the \( IR \) brane. Effective brane actions are generated which guarantee that
$S_{cl}[\phi_0]$ does not change. By moving the $IR$ brane up to $z = z_{UV}$, by construction $S_{cl}[\phi_0]$ equals the effective $IR$ brane action. Using (1.1), the couplings of the effective $IR$ brane action can be identified with the correlation functions of the CFT. The couplings on the effective brane "run" in a way that resembles an ordinary renormalization group (RG) flow. In particular, in the limit where the physical $IR$ brane is at infinity, corresponding to the RS2 scenario [8], all the brane couplings flow to a non-local fixed point. Notice that the running of the brane couplings should not be confused with the RG flow of the observables in the dual field theory (see for example [9]), since we are keeping the cutoff, represented by the location of $UV$ brane, fixed.

This formalism appears particularly appropriate for computations in the RS1 scenario. In the holographic interpretation, this model is dual to a CFT with a cutoff $\Lambda = 1/z_{UV}$, where conformal invariance is also broken in the infrared by the $IR$ brane at the energy scale $1/z_{IR}$. Since conformal invariance is broken, the couplings on the effective brane are now not at their fixed points but, at energies $E > 1/z_{IR}$, we can consider this as a small deviation from conformality. Brane actions can be included with ease, they simply modify the initial condition for the flow at $z_{IR}$.

The paper is organized as follows. In Section 2 we present the general techniques in the case of the 2−point function of a scalar field and reproduce well known results. In Section 3 we extend the procedure to 3− and 4−point functions and consider the general structure of higher-point functions. In Section 4 we apply the brane running method to holographic computations in the RS1 model. Section 5 contains the conclusions. A more detailed analysis of the 2−point function is left to the Appendix.

2 2−point functions

We start considering a bulk scalar field propagating in an RS1-type geometry. We will work in Euclidean AdS$_{d+1}$ with the metric in Poincaré coordinates:

$$ds^2 = \frac{L^2}{z^2}(d^d x^2 + dz^2)$$

(2.1)

where $L$ is the radius of AdS$_{d+1}$. The radial dimension $z$ is compactified on an orbifold $S_1/\mathbb{Z}_2$ with fixed points located at $z_{UV}$ (the ultraviolet brane) and at $z_{IR}$ (the infrared brane). One can think of this configuration as a regularization of the full AdS, which can be recovered in the limit $z_{UV} \rightarrow 0$ and $z_{IR} \rightarrow \infty$.

The Euclidean action of a free scalar of mass $m$ is:

$$S = S_{bulk} + S_{UV} + S_{IR}$$

(2.2)
where:

\[
S_{\text{bulk}} = \frac{1}{2} \int d^d x \int d z \sqrt{G} (G^{MN} \partial_M \phi \partial_N \phi + m^2 \phi^2)
\]

\[
S_{\text{UV}} = \frac{1}{2} \int d^d x \sqrt{g_{\text{UV}}} \frac{\lambda_{\text{UV}}}{L} \phi
\]

\[
S_{\text{IR}} = \frac{1}{2} \int d^d x \sqrt{g_{\text{IR}}} \frac{\lambda_{\text{IR}}}{L} \phi
\]

(2.3)

g_{\text{UV}} \text{ and } g_{\text{IR}} \text{ are the induced metrics on the branes. We will consider } \lambda_{\text{UV}} \text{ and } \lambda_{\text{IR}} \text{ to be derivative couplings. These are the most general brane actions quadratic in the fields and compatible with } d-\text{dimensional Poincaré invariance.}

Henceforth we take \( L = 1 \). We systematically use the Fourier transform of the field \( \phi \) in the directions parallel to the brane:

\[
\phi(x, z) = \int d^d p \ e^{ipx} \phi(p, z)
\]

(2.4)

In momentum space, the equation of motion is given by:

\[
[z^2 \partial_z^2 + (1 - d) z \partial_z - p^2 z^2 - m^2 - z \delta(z - z_{\text{UV}}) \lambda_{\text{UV}}(p) - z \delta(z - z_{\text{IR}}) \lambda_{\text{IR}}(p)] \phi(p, z) = 0
\]

(2.5)

The brane actions imply boundary conditions on the fields at \( z_{\text{UV}} \) and at \( z_{\text{IR}} \). Assuming that field \( \phi \) is even on the orbifold we have\(^1\):

\[
\left. z \frac{\partial}{\partial z} \phi(p, z) \right|_{z = z_{\text{IR}}} = -\frac{\lambda_{\text{IR}}}{2} \phi(p, z_{\text{IR}})
\]

(2.6)

Since we are interested in computing \( S_{\text{cl}}[\phi_0] \), we consistently impose Dirichlet boundary conditions on the \( \text{UV} \) brane:

\[
\phi(p, z_{\text{UV}}) = \phi_0(p)
\]

(2.7)

In the AdS/CFT correspondence, the on-shell value of the action on AdS as a function of the boundary values of the fields is the generating functional of the correlation functions of the gauge invariant operators of the CFT. In particular, a bulk scalar field of mass \( m \) is dual to a scalar operator of the CFT with conformal dimension \( \Delta = d/2 + \sqrt{(d/2)^2 + m^2} \). One popular way to compute the on-shell action is to consider a Dirichlet boundary problem at \( z = z_{\text{UV}} \)\(^2\) and use solutions of the wave-equation (for the two \( 2-\)point function, \( S_{\text{cl}}[\phi_0] \) depends only

\(^1\text{Alternatively one can always impose Dirichlet boundary condition. This corresponds to a different definition of the theory.}

\(^2\text{In certain situations the dimension of the operator in the CFT is given by } \Delta = d/2 - \sqrt{(d/2)^2 + m^2} \text{. This case can be obtained by adding appropriate brane actions on the } \text{UV} \text{ brane but we will not pursue this possibility here.}

3
on the asymptotic behavior of the solutions near the boundary; explicit wave-functions are necessary to compute higher-point functions).

We will now see how the dependence of the on-shell action on the boundary values of the fields can be obtained by flowing in the space of theories with different sizes of the extra-dimension. For applications to the AdS/CFT correspondence, we are only interested in the effective action seen by an observer living on the UV brane. We consider a new theory with an effective IR brane located at \( a < z_{IR} \). Requiring that the original theory and the theory with the effective IR brane at \( a \) have precisely the same solutions in the overlapping region leaves any observable on the UV brane unchanged. Technically this program is accomplished including brane actions on the effective IR brane which provide the same boundary conditions at \( a \) as the one implied by the original brane action at \( z_{IR} \). This construction is equivalent to requiring that \( S_{cl}[\phi_0] \) is invariant. Since the whole information about the CFT is contained in \( S_{cl}[\phi_0] \), the AdS theory with the effective IR brane at \( a \) describes the same CFT.

At the quadratic level the necessary effective brane action is:

\[
S_b(a) = \frac{\pi}{a^d} \int d^d p d^d p' \delta(p + p') \phi(p', a) \lambda_2(a) \phi(p, a)
\]  

(2.8)

A few remarks are in order. The coupling \( \lambda_2(a) \) has an explicit \( a \) dependence and an implicit one from the momentum (this follows from \( d \)-dimensional Poincaré invariance). If the original brane action at \( z_{IR} \) is local, i.e. it has an expansion polynomial in \( p \), the flow respects such a property. However, when the physical IR brane is removed to infinity, as in the full AdS/CFT or in the RS2 model, non-local terms will also be generated. This is easily understood from a field-theoretic point of view. When AdS extends to infinity we have a continuum of \( d \)-dimensional particles which generates branch cuts in the effective action seen by an observer located on the UV brane.

These non-local terms are crucial since they reproduce the correlation functions of the CFT at non-coincident points. Therefore we consider brane actions which contain local and non-local terms:

\[
\lambda_2(a) = \lambda_2^{loc.}(a) + \lambda_2^{n.loc.}(a)
\]  

(2.9)

\( \lambda_2^{loc.} \) has a polynomial expansion in momentum:

\[
\lambda_2^{loc.}(a) = \sum_j \lambda_2^{(2j)}(a)(g_{a \mu \nu}^\mu p_{\mu} p_{\nu})^j
\]  

(2.10)

where \( g_{a \mu \nu}^\mu \) is the induced metric at \( z = a \). The precise form of \( \lambda_2^{n.loc.} \) depends on the value of the bulk mass.

The flow of the brane couplings, as a function of the radial coordinate \( a \), can be cast in a form that resembles an ordinary RG flow. In the theory with the brane action (2.8), the
boundary condition at \( a \) is:
\[
a \frac{\partial}{\partial a} \phi(p,a) = -\frac{\lambda_2(a)}{2} \phi(p,a)
\]
(2.11)

In order to compute the differential flow of \( \lambda_2 \), we take the logarithmic derivative with respect to \( a \) of (2.11). Since by hypothesis the solutions remain unchanged in the overlapping region, we use the bulk equation of motion to eliminate the second derivatives of the fields. Requiring that the resulting equation is satisfied for any value of \( \phi \), we obtain the flow equation of \( \lambda_2 \):
\[
a \frac{d}{da} \lambda_2 = \frac{\lambda_2^2}{2} + d\lambda_2 - 2m^2 - 2a^2p^2
\]
(2.12)

This is the main equation of this section. It contains the same information about the CFT as does the original action. One can integrate this equation with the boundary condition:
\[
\lambda_2(z_{IR}) = \lambda_{IR}
\]
(2.13)

to obtain the couplings of the effective brane at \( a \).

Solving (2.12) allows one to compute the on-shell value of the action in terms of the values of the fields at \( z_{UV} \). Explicitly, "running" the effective brane all the way down to the \( UV \) brane, \( S_{cl}[\phi_0] \) is simply given by the sum of the \( UV \) and the effective brane actions, because the bulk contribution goes to zero. Assuming for simplicity that \( \lambda_{UV} = 0 \), we have from (2.8):
\[
S_{cl}[\phi_0] = S_b(z_{UV}) = \frac{\pi}{z_{UV}^d} \int d^dp \delta(p+p') \phi_0(p') \lambda_2(z_{UV}) \phi_0(p)
\]
(2.14)

The flow equation (2.12) has a fixed point in the sense \( a \partial_a \lambda_2(a) = 0 \) (that is, the coupling depends on \( a \) only through the dependence on momentum):
\[
\lambda_2^{f.p.}(pa) = (2\nu - d) + 2pa \frac{K_{\nu-1}(pa)}{K_\nu(pa)}
\]
(2.15)

where \( K_\nu \) is the modified Bessel function of order \( \nu = \sqrt{(d/2)^2 + m^2} \). In the limit where the \( IR \) brane is at infinity, the physics on the \( UV \) brane does not depend on the \( IR \) brane. In this case (see Appendix) the coupling \( \lambda_2(a) \) is a function of \( pa \) only: it is at its fixed point. In other words, choosing the brane coupling at the fixed point (2.15) is equivalent, from the point of view of an observer living on the \( UV \) brane, to removing the \( IR \) brane to infinity. In the Appendix we show that the flow equation (2.12) has in general a line of fixed points, but these correspond to solutions of the wave-equation which are not regular at infinity, so they are rejected. One can check that, in the limit \( z_{IR} \to \infty \) and zero brane actions, \( \lambda_2(a) \) approaches the fixed point (2.15).

According to the AdS/CFT prescription (1.1), \( \lambda_2(z_{UV}) \) is, up to a normalization, the 2–point function of a scalar operator of the CFT of dimension \( \Delta = d/2 + \nu \) (in the large
$N$ limit and strong 't Hooft parameter). In fact, with $\lambda_2$ at the fixed point (2.15), the brane action evaluated at $z_{UV}$ coincides up to a factor of two (coming from working in the orbifold covering space) with the standard AdS/CFT on-shell action computed, for example, in [11]. The expansion of (2.15) for integer $\nu$ is:

$$\lambda_2^{f.p.}(pa) = 2\nu - d + \frac{p^2 a^2}{\nu - 1} + \ldots + \tilde{\lambda}_2^{(2\nu)}(pa)^{2\nu} \log pa + \ldots$$

(2.16)

where the coefficient $\tilde{\lambda}_2^{(2\nu)}$ depends on $\nu$ only. For non-integer $\nu$ one finds a similar expansion with first non-analytic term $(pa)^{2\nu}$. Notice that, as promised, the brane action necessary to reproduce the infinite space limit is non-local. In AdS/CFT computations one then proceeds taking the limit $z_{UV} \to 0$ in (2.14). The divergent local terms in $S_{cl}[\phi_0]$ need to be renormalized away [12]. The non-local term $p^{2\nu} \log p$ reproduces the 2−point function at non-coincident points of a scalar operator with conformal dimension $\Delta = d/2 + \nu$.

## 3 Interactions

Higher-point functions can be computed in a very similar way to the 2−point functions, by integrating out bulk degrees of freedom.

### 3.1 3−point functions

As an example we will consider the case of cubic interactions. The bulk action in momentum space contains:

$$S_{int} = 2\pi \sigma^{ijk} \int \sqrt{G} dz d^d p d^d q d^d k \delta(p + q + k) \phi_i(p, z) \phi_j(q, z) \phi_k(k, z)$$

(3.1)

where $\phi_i(x, z)$ are scalar fields of mass $m_i$ and $\sigma^{ijk}$ is symmetric in the indexes. The bulk equation of motion reads:

$$[z^2 \partial_z^2 + (1 - d)z \partial_z - z^2 p^2 - m^2)]\phi_i(p, z) - 3\sigma^{ijk} \int d^d q \phi_j(p - q, z) \phi_k(q, z) = 0$$

(3.2)

In this case the effective brane action also contains cubic and higher order terms:

$$S_b(a) \supset \frac{2\pi}{a^6} \int d^d p d^d q d^d k \delta(p + q + k) \lambda_3^{ijk}(p, q, k) \phi_i(p, a) \phi_j(q, a) \phi_k(k, a)$$

(3.3)

The boundary condition at $a$ becomes:

$$a \frac{\partial}{\partial a} \phi_i(p, a) = -\lambda_i^{(p)}(p, a) - \frac{3}{2} \int d^d q \lambda_3^{ijk}(p, q - p, q) \phi_j(q - p, a) \phi_k(q, a)$$

(3.4)
where $\lambda_i^2$ is the quadratic brane coupling of the field $\phi_i$.

To compute the flow equation for the coupling $\lambda_{ijk}^3$, we proceed by taking the logarithmic derivative of (3.4), as in the case of the 2–point function. We then use the bulk equation of motion and require that the equation is satisfied for any value of the fields. With a cubic brane action this can be done up to order $\phi^2$ in the fields. Of course, this is because a cubic interaction generates higher-point functions as well. The important point is that, at the classical level, lower order point functions do not mix with higher orders ones, so the flow of the coupling $\lambda_i$ depends only on the couplings $\lambda_j$ with $j \leq i$.

The equation for $\lambda_{ijk}^3$ is:

$$a \frac{d}{da} \lambda_{ijk}^3 (-p, p - q, q) = -2\sigma_{ijk} + d\lambda_{ijk}^3 (-p, p - q, q) + \frac{1}{2} \lambda_{ijk}^3 (-p, p - q, q) [\lambda_i^2(p) + \lambda_j^2(p - q) + \lambda_k^2(q)]$$

(3.5)

While this equation can be difficult to solve in general, it can be solved perturbatively expanding in powers of momenta, as explained in the Appendix for the case of the 2–point function.

In the infinite AdS case, each brane coupling should be set at the fixed point, so they do not depend explicitly on $a$. One can check that the fixed point in this case is given by:

$$\lambda_{ijk}^3 (-p, p - q, q) = 2\sigma_{ijk} a d \int_a^{\infty} dz \frac{1}{z^{d+1}} \left( \frac{z}{a} \right)^d K_{\nu_i}(-pz)K_{\nu_j}((p-q)z)K_{\nu_k}(qz) \frac{K_{\nu_i}(-pa)K_{\nu_j}((p-q)a)K_{\nu_k}(qa)}{K_{\nu_i}(-pa)K_{\nu_j}((p-q)a)K_{\nu_k}(qa)}$$

(3.6)

Notice that, since the $\beta$–function for $\lambda_{ijk}^3$ is linear in $\lambda_{ijk}^3$, the fixed point is completely determined by $\lambda_{ij}^{p}$. The fixed point (3.6) is just the 3–point function in the limit $z_{IR} \to \infty$, computed with bulk-to-boundary propagators [14].

### 3.2 Higher-point functions

The method of brane running is completely general and can be extended to arbitrary order point functions. The computation of 4– and higher-point functions is complicated in the AdS/CFT correspondence because it involves bulk-to-bulk AdS propagators. In our case, the structure of the differential equations for the higher-point functions is similar to the case of the 3–point function and can be readily understood in a diagrammatic way.

In order to compute the 4–point function we need to include a quartic brane action:

$$S_b(a) \supset \frac{1}{a^d} \int d^d x \lambda_{ijkl}^4 \phi_i \phi_j \phi_k \phi_l$$

(3.7)
Following the same steps as for the 3–point function, one obtains:

\[
a \frac{d}{da} \lambda^{ijkl}_4 = d \lambda^{ijkl}_4 + \frac{\lambda^{ijkl}_4}{2} [\lambda^i_2(p) + \lambda^j_2(p - q - k) + \lambda^k_2(q) + \lambda^l_2(k)] + \\
+ \frac{9}{8} [\lambda^m^{imk}(-p, p - q, q) \lambda^m^{mjl}(q - p, p - q - k, k) + \lambda^m^{ijm}(-p, p - q - k, q + k) \lambda^m^{mlk}(-q - k, q, k)]
\]

(3.8)

In the previous equation, the momentum dependence of the coupling is \(\lambda_4(-p, p - q - k, q, k)\). The fixed point of (3.8) is, up to normalization, the amplitude for the 4–point function in the AdS/CFT which can be expressed in terms of bulk-to-bulk and bulk-to-boundary propagators.

We now analyze the general structure of the \(\beta\)--functions for the couplings. We consider in particular the 4–point function but the same considerations hold for higher-point functions. Schematically, the diagrams contributing to the 4–point function when brane actions are included are represented in the figure below.

Figure 1: Diagrams contributing to the "running" of \(\lambda_4\) at the classical level. The external legs are located on the \(\text{UV}\) brane and the interactions take place on the effective brane located at \(a\).

To move the brane from \(a\) to \(a - da\), we need to provide counter-terms for the degrees of freedom which have been integrated out. As a consequence, the infinitesimal variation of \(\lambda_4\) contains a contribution proportional to \(\lambda_3^2\), a contribution proportional to \(\lambda_2 \lambda_4\) as well as a contribution linear in \(\lambda_4\). A quartic bulk interaction would act as a source in the \(\beta\)–function of \(\lambda_4\). The dependence on the momenta can be worked out as in ordinary Feynman diagrams.

4 Applications

In this section we apply the brane running method to the Randall-Sundrum scenario [7]. We take \(d = 4\).
In the full AdS/CFT correspondence, a theory on AdS is equivalent to a pure conformal field theory living on the boundary. In the previous analysis the UV brane and the IR brane should be understood as regulators of the theory so the physical quantities are extracted in the limit $z_{UV} \to 0$ and $z_{IR} \to \infty$. As we have argued, the second limit (corresponding to the geometry of the RS2 model) implies that all the couplings on the effective brane are at their fixed points. In the RS1 scenario, five dimensional AdS is truncated by two physical branes parallel to the boundary, placed at the fixed points of an orbifold. Since small values of the coordinate $z$ correspond to the ultraviolet of the CFT, the presence of the UV brane represents a cutoff applied to the CFT. On the other hand, the IR brane modifies the space only at large $z$ so naively it corresponds, in the holographic picture, to breaking (spontaneously) conformal invariance in the infrared, at a scale $1/z_{IR}$. It should be clear from the present paper that this conclusion may not hold when brane actions are included: theories with different size of the extra-dimension can have the same CFT dual. Since for phenomenological applications one takes $z_{IR}/z_{UV} \sim 10^{15}$, the theory should appear approximately conformal for a large range of energies, namely $1/z_{IR} < E < 1/z_{UV}$.

To any order in the fields, the dependence of the action on the boundary values of the fields can be computed integrating the flow equations presented in the previous sections. This can be done perturbatively in $p$ as shown in the Appendix for the 2–point function. In particular it is straightforward, even for higher-point functions, to compute the zero momentum dependence of the coupling $\lambda_n$. The leading dependence on the external momentum is also not hard to compute. Since the $IR$ brane breaks conformal invariance in the infrared, the brane couplings are not at a fixed point, but acquire an explicit dependence on the scale $a$.

In the case of the 2–point function, equation (2.12) can be solved explicitly, the solution being:

$$\lambda_2(a) = 2\nu - 4 + 2pa \frac{K_{\nu-1}(pa)}{K_\nu(pa)} + C \frac{I_{\nu-1}(pa)}{I_\nu(pa)}$$

(4.1)

The integration constant $C$ is determined by the boundary condition at the $IR$ brane, namely $\lambda_2(z_{IR}) = \lambda_{IR}$. This allows the inclusion in a simple and systematic way of arbitrary brane actions. For example, for a massless scalar and $\lambda_{IR} = 0$, corresponding to ordinary Neumann boundary condition, the result is:

$$\lambda_2(a) = 2pa \frac{I_1(pz_{IR})}{I_2(pa)K_1(pz_{IR}) + I_1(pz_{IR})K_2(pa)}$$

(4.2)

For $a = z_{UV}$ this is just the analytic continuation to Euclidean AdS of the inverse of the brane-to-brane propagator of a massless scalar computed in [15]. In general, $\lambda_2(z_{UV})$ is the inverse of the brane-to-brane propagator, so the zeros in $p$ of $\lambda_2(z_{UV})$ correspond to the masses of the Kaluza-Klein (KK) modes.
For \( p z_{IR} < 1 \) one can expand \( \lambda_2(a) \) in powers of \( p \). The expansion is now completely polynomial in momentum. Technically this happens because if the boundary condition is local, this property will be preserved by the flow. From the CFT point of view, this fact is simply the statement that below the scale \( 1/z_{IR} \), conformal symmetry is completely broken, and in particular, a mass gap is generated. On the AdS side we have a discrete set of 4D particles whose mass scale is set by \( 1/z_{IR} \). This discrete set of particles gives rise to isolated poles in the propagator but no branch cuts. Therefore, at energies below the masses of the KK modes, this system should be describable in terms of a local action.

At energies above \( 1/z_{IR} \), conformal invariance is approximately restored. For \( p z_{UV} < 1 \), i.e. energies below the cutoff of the CFT, we can expand \( \lambda_2(z_{UV}) \) around \( z_{UV} = 0 \). In the case of the massless scalar (4.2) we have:

\[
\lambda_2(z_{UV}) = p^2 z_{UV}^2 + \frac{1}{2} (\gamma + \log \frac{pz_{UV}}{2}) p^4 z_{UV}^4 - \frac{K_1(pz_{IR})}{2I_1(pz_{IR})} p^4 z_{UV}^4 + O(z_{UV}^6) \tag{4.3}
\]

In the limit \( z_{IR} \to \infty \) we recover the expansion of the fixed point. This should be expected since in this limit all the couplings flow to their fixed points. Using the asymptotic expansion of the Bessel functions, it is easy to see that the deviation from \( \lambda_{f.p.}^2 \) becomes exponentially small at energies greater that \( 1/z_{IR} \). Since for large momenta the presence of the IR brane represents a small deviation from conformality, all the brane couplings are close to the fixed point. In this regime it is useful to simplify the flow equation expanding to linear order around \( \lambda_{f.p.}^2 \):

\[
a \frac{d}{da} \alpha_2 = \alpha_2 \lambda_{f.p.}^2 + d \alpha_2 \tag{4.4}
\]

where \( \alpha_2 = \lambda_2 - \lambda_{f.p.}^2 \). To leading order, for \( pa > 1 \), the solution of the previous equation is simply \( \alpha_2 = C \ a \ e^{2pa} \), independently on \( \nu \). As we move the effective brane to smaller \( a \), \( \alpha_2(a) \) becomes exponentially suppressed. Similar manipulations can be done for higher-point functions.

Localized fields can be naturally included in this formalism. This case is important for phenomenological applications. For example, in the original proposal by Randall and Sundrum, in order to solve the hierarchy problem, the Standard Model fields were localized on the IR brane. For fields localized on the UV brane, it is obvious that their action should be added to the effective action. From the CFT point of view, fields living on the UV brane are interpreted as fields external to the CFT and coupled to gauge invariant operators of the CFT so it is natural to add the action of the CFT and that of the external fields. In the case of fields localized on the IR brane, or in the bulk, the analysis is more intricate because these fields

\[^3\text{For the case } -d^2/4 \leq m^2 < 0, \text{ i.e. tachyons satisfying the lower bound on the masses of scalars in AdS}_{d+1}, \text{ the KK spectrum also contains a single tachyon whose mass squared is } O(-1/z_{UV}^2) \ [16].\]
couple only indirectly to the UV brane. As an example, following [14], we consider a free scalar field coupled to an external source $j$ localized at $z = z_0$. In $d + 1$ dimensions, the AdS action contains:

$$ S \supset \int d^d x dz \sqrt{G} j \phi \delta(z - z_0) \tag{4.5} $$

Consistency requires the brane action:

$$ S_b(a) = \frac{1}{a^d} \int d^d x \lambda_1 \phi + \frac{1}{2a^d} \int d^d x \phi \lambda_2 \phi \tag{4.6} $$

The running of $\lambda_1$ is given by:

$$ a \frac{d}{da} \lambda_1 = d \lambda_1 + \frac{\lambda_1 \lambda_2}{2} \tag{4.7} $$

while the $\beta-$function of $\lambda_2$ remains unchanged. Notice that only in this particular case a coupling depends on higher order ones.\(^4\) For a localized source in the case where the IR brane is at infinity, $\lambda_2$ will still be at its fixed point (2.15). It is not hard to check that the solution of (4.7) is:

$$ \lambda_1 = \left( \frac{a}{z_0} \right)^{d/2} \frac{K_\nu(pz_0)}{K_\nu(pa)} j(p) \tag{4.8} $$

A tadpole for the field $\phi$ is generated in the effective field theory of an observer on the UV brane. On the CFT side, this corresponds to an expectation value for the dual operator.

### 5 Conclusions and Outlook

In this paper we have shown how to compute the value of the on-shell AdS action of a scalar field by flowing in the space of theories with a different size for the extra-dimension. By integrating out bulk degrees of freedom, we generate effective brane actions which reproduce exactly the same physics in the restricted region. To any order in the fields, the dependence of the on-shell action on the boundary values of the fields at $z_{UV}$ is obtained by solving the flow equations for the couplings on the effective brane. In principle, this procedure does not require the knowledge of the bulk-to-boundary and bulk-to-bulk propagators. The values of the couplings are related in a simple way to the correlation functions of the CFT. In the case of infinite AdS or RS2, the brane couplings are at their fixed points, corresponding to an unbroken CFT.

This formalism is particularly appropriate for holographic computations in the RS1 model. Here the couplings on the effective brane are not at the fixed points but acquire an explicit dependence on the radial coordinate. At energies much above the scale set by the $IR$ brane, corresponding to the scale where conformal invariance is broken, the couplings are very close to the fixed points so we can simplify the flow equations.

\(^4\)If bulk interactions are included the $\beta-$function of the coupling $\lambda_i$ will depend on the couplings up to $\lambda_{i+1}$.\(^1\)
Gauge fields and fluctuations of the metric can be included in a very similar way. The
relevant steps are presented in [6], where the brane running is used to compute the effective
field theory of an observer living on the IR brane. The extension to fermionic fields is non-trivial
because the wave-equation is a first order differential equation in this case.

More in general, the method of brane running can be used in geometries which contain
a Poincaré invariant subspace. The structure of the $\beta-$functions for the couplings would be
similar to the one in the present paper. In this case though, the brane couplings, even in the
infinite space limit, will not be at a fixed point.

Computation of the 2–point function

In this Appendix we give a self-contained derivation of the flow equation for the coupling $\lambda_2$
and carefully study the solutions.

The boundary condition at $a$ determined by the brane action is:

$$z\partial_z \phi(p, z) \bigg|_a = -\frac{\lambda_2(a)}{2}\phi(p, a)$$

The bulk equation of motion is:

$$(z^2 \partial_z^2 + (1 - d)z\partial_z - p^2 z^2 - m^2)\phi(p, z) = 0$$

We are interested in the differential flow of the coupling $\lambda_2$. By assumption the solution of
the equations of motion do not depend on the location of the brane. This physical condition
determines a (classical) flow for $\lambda_2$. Taking the logarithmic derivative of $\phi(p, a)$ with respect to $a$
we obtain:

$$(a \frac{d}{da} \lambda_2 + \lambda_2 a\partial_a + 2a\partial_a + 2a^2\partial_a^2)\phi(p, a) = 0$$

Using the bulk equation of motion to eliminate the second derivative and requiring that this
new equation is satisfied for any value of the field $\phi(p, a)$, we find the flow equation:

$$a \frac{d}{da} \lambda_2 = \frac{\lambda_2^2}{2} + d\lambda_2 - 2m^2 - 2p^2 a^2$$
The solutions of this equation are functions of $pa$. The boundary condition at $z_{IR}$ introduces a dependence on $pz_{IR}$. A quick way to find the solutions of (4) is to use explicit wave-functions and substitute in (1). The solution of the bulk equation of motion is:

$$\phi(p, z) = \frac{z^{d/2} (AK_{\nu}(pz) + BI_{\nu}(pz))}{AK_{\nu}(pa) + BI_{\nu}(pa)}$$ (5)

where $I_{\nu}$ and $K_{\nu}$ are Bessel’s functions of order $\nu = \sqrt{(d/2)^2 + m^2}$. Plugging in (1) and using properties of the Bessel’s functions we find:

$$\lambda^2(a) = 2\nu - d + 2pa \frac{AK_{\nu-1}(pa) - BI_{\nu-1}(pa)}{AK_{\nu}(pa) + BI_{\nu}(pa)}$$ (6)

The coefficients $A$ and $B$ have a dependence on $pz_{IR}$ determined by the IR brane. Particularly important for the applications to the AdS/CFT are the solutions of this equation which depend on $pa$ only. We call these solutions fixed points because the couplings in the expansion of $\lambda_2$ are independent on $a$ in this case. From (6) we see that the flow equation has a line of fixed points depending on the ratio $A/B$ (with $A/B$ independent of $p$). Setting $\lambda_2$ at a fixed point is physically equivalent, for an observer living on the UV brane, to removing the IR brane to infinity. Regularity at infinity selects the wave-function $K_{\nu}$ so the relevant fixed point corresponds to $B = 0$.

For illustrative purposes we now show an alternative method to compute the fixed points of (4). The same technique could be used to solve the equations for the higher order couplings or to study the 2–point functions in backgrounds which are only asymptotically AdS.

Equation (4) can be solved iteratively expanding in powers of $p$. Notice that for the fixed points the momentum expansion is the same as the expansion around $a = 0$, that is a near boundary analysis. For simplicity, we will consider the case of $\nu$ integer which is the most common in the string theory literature. We start with the following ansatz for the solution:

$$\lambda_2(a) = \lambda^{(2)}_2(a) + \lambda^{(2n)}_2(pa)^2 + \ldots + \lambda^{(2\nu)}_2(pa)^{2\nu} + \ldots$$ (7)

Substituting in the flow equation we obtain a set of coupled differential equations for the coefficients $\lambda^{(2i)}_2$:

$$a\partial_a \lambda^{(0)}_2 = \frac{(\lambda^{(0)}_2)^2}{2} + d\lambda^{(0)}_2 - 2m^2$$
$$a\partial_a \lambda^{(2)}_2 = \lambda^{(2)}_2 \lambda^{(0)}_2 + (d - 2)\lambda^{(2)}_2 - 2$$
$$a\partial_a \lambda^{(2n)}_2 = \lambda^{(2n)}_2 (\lambda^{(0)}_2 + d - 2n) + \frac{1}{2} \sum_{i+j=n} \lambda^{(2i)}_2 \lambda^{(2j)}_2$$ (8)

For the fixed points all the derivatives are equal to zero so we have a set of algebraic equations. The solution of the first equation in (8) is:

$$\lambda^{(0)}_2 = -d \pm 2\nu$$ (9)
The solution with the $-$ sign corresponds to the fixed point with $I_\nu$ only. This solution has an expansion purely polynomial in momentum. In position space this generates only contact interactions. With the choice of the $+$ sign we can solve (18) iteratively only up to the order $2\nu$. This equation is inconsistent. In order to find a solution we need to include a term $\tilde{\lambda}^{(2\nu)}(qa)^{2\nu}\log qa$ in the expansion of $\lambda_2$. Now the equation $(2\nu)$ determines the coefficient $\tilde{\lambda}^{(2\nu)}$ while $\lambda_2^{(2\nu)}$ remains unconstrained. The fact that $\lambda_2^{(2\nu)}$ is undetermined is of course related to possibility of choosing $A/B$ in (16).
