(Dated: May 30, 2007)

The static Coulomb potential of Quantum Electrodynamics (QED) is calculated in the presence of a strong magnetic field in the lowest Landau level (LLL) approximation using two different methods. First, the vacuum expectation value of the corresponding Wilson loop is calculated perturbatively in two different regimes of dynamical mass $m_{\text{dyn.}}$, i.e., $|q_\parallel|^2 \ll m_{\text{dyn.}}^2 \ll |eB|$ and $m_{\text{dyn.}}^2 \ll |q_\parallel|^2 \ll |eB|$, where $q_\parallel$ is the longitudinal components of the momentum relative to the external magnetic field $B$. The result is then compared with the static potential arising from Born approximation. Both results coincide. Although the arising potentials show different behavior in the aforementioned regimes, a novel dependence on the angle $\theta$ between the particle-antiparticle’s axis and the direction of the magnetic field is observed. In the regime $|q_\parallel|^2 \ll m_{\text{dyn.}}^2 \ll |eB|$, for strong enough magnetic field and depending on the angle $\theta$, a qualitative change occurs in the Coulomb-like potential; Whereas for $\theta = 0, \pi$ the potential is repulsive, it exhibits a minimum for angles $\theta \in ]0, \pi[$.

I. INTRODUCTION

Chiral symmetry plays an important role in elementary particle physics. It has been known\textsuperscript{[1]} for some time that QED, in addition to the familiar weak-coupling phase, may have a nonperturbative strong coupling phase, characterized by spontaneous chiral symmetry breaking\textsuperscript{[2]}. The existence of this new phase was exploited in a novel interpretation of the multiple correlated and narrow peak structures in electron and positron spectra observed at GSI several years ago\textsuperscript{[3]}. According to this scenario the electron-positron peaks are due to the decay of a bound electron-positron system formed in the new QED phase induced by a strong and rapidly varying electromagnetic field which is present in the neighborhood of a colliding heavy ions. It is therefore of great interest to investigate whether background fields, such as constant magnetic fields, can potentially induce chiral symmetry breaking in gauge theories and lead eventually to the formation of chiral symmetry breaking fermion condensate $\langle \bar{\psi} \psi \rangle$ and a dynamically generated fermion mass.

Indeed, the magnetic catalysis of dynamical chiral symmetry breaking has been established as a universal phenomenon in 2+1 and 3+1 dimensions\textsuperscript{[2, 4]}. According to these results, even at the weakest

\textsuperscript{*}Electronic address: sadooghi@physics.sharif.edu
attractive interaction between fermions, a constant magnetic field leads to the generation of a fermion dynamical mass. The essence of this effect is the dimensional reduction $D \rightarrow D - 2$ in the dynamics of fermion pairing in a magnetic field, which arises from the fact that the motion of charged particles is restricted in directions perpendicular to the magnetic field. It is believed that at weak coupling this dynamics is dominated by the lowest Landau level (LLL). The magnetic catalysis is not only interesting from purely fundamental point of view, but it has potential application in condensed matter physics [5] and cosmology [6].

In this paper we are interested on the static potential between the particle and antiparticle in the presence of a strong constant magnetic field. The potential produced by a point electric charge placed into a constant magnetic field is recently calculated in [7]. It is shown that the standard Coulomb law is modified by the vacuum polarization arising in the external magnetic field. Here, since the vacuum polarization component, taken in one-loop approximation, grows linearly with the magnetic field, a scaling regime occurs in the limit of infinite magnetic field. The scaling regime implies a short range character of interaction, expressed as Yukawa law

$$V(R) = -\frac{\alpha e^{-M_\gamma R}}{R}, \quad \text{with} \quad M_\gamma \equiv \sqrt{\frac{2\alpha |eB| N_f}{\pi}},$$

where $R \equiv |x|$ and $M_\gamma$ is the photon mass.

In the present work, we will determine anew the potential $V(x)$ between the particle-antiparticle pair in the presence of a constant magnetic field in the LLL approximation. Although our method differs essentially from the analytic methods used in [7], leading to (I.1), our result is indeed consistent with this potential.

To determine the fermion-antifermion potential, we will first compute perturbatively the vacuum expectation value (vev) of a Wilson loop of a static fermion-antifermion pair for large Euclidean time. In [8], the same perturbative method is used to determine the quark-antiquark potential of ordinary QCD. At one-loop level it is shown to be

$$V(R) = -C \frac{e^2}{4\pi R} \left( 1 + \frac{11e^2}{8\pi^2} \ln \frac{R}{a} \right),$$

where $C \equiv \frac{1}{2} \text{tr} (\lambda^a \lambda^a)$ is the trace over the product of Gell-Mann matrices $\lambda^a$, and $a^{-1}$ is the UV cutoff parameter. Using the same idea, we will determine the potential of a point charged particle in the external magnetic field. Eventually, we will compare our result with the modified Coulomb potential from a semi-classical Born approximation. In the regime of LLL dominance, we will consider two different regions of dynamical mass, $|q_\parallel|^2 \ll m_{dyn}^2 \ll |eB|$ and $m_{dyn}^2 \ll |q_\parallel|^2 \ll |eB|$, separately. Here, $q_\parallel$ is the longitudinal component of the momentum with respect to the direction of the external magnetic field. We will show that the potential in the regime $|q_\parallel|^2 \ll m_{dyn}^2 \ll |eB|$ has the general form of a modified Coulomb potential

$$V_1(R, \theta) = -\frac{\alpha}{R} \left( A_1(\alpha, \theta) - \frac{\gamma A_2(\alpha, \theta)}{R^2} + \frac{\gamma^2 A_3(\alpha, \theta)}{R^4} \right), \quad \text{with} \quad \gamma \equiv \frac{2\alpha}{3\pi m_{dyn}^2},$$

1 Here, to determine the potential in the LLL approximation, we will use the full photon propagator in the presence of a strong magnetic field [10] in the LLL approximation. In [10], it is shown that the full photon propagator depends on the dynamical mass $m_{dyn}$, which is calculated nonperturbatively in [4]. Thus although our method is a perturbative one, the result depends automatically on a parameter which is determined nonperturbatively.
and in the regime $m_{\text{dyn.}}^2 \ll |q_\parallel^2| \ll |eB|$ has the form of a Yukawa-like potential

$$V_2(R, \theta) = -\frac{\alpha}{(1 - \frac{2}{\pi})g(\theta)R} \left| e^{\text{eff.}}R \right|, \quad \text{with} \quad M_{\text{eff.}}(\theta) \equiv g(\theta)\sqrt{\frac{2\alpha|eB|}{\pi}}, \quad (I.4)$$

where $A_i, i = 1, 2, 3$ in (I.3) and $g(\theta)$ in (I.4) will be calculated exactly in Sec. III. In (I.3) as well as (I.4), $\theta$ is the angle between the particle-antiparticle axis and the direction of the magnetic field. Up to this explicit novel dependence on the angle $\theta$, the potential $V_2(R, \theta)$ from (I.4) is comparable with the potential (I.1) from [7]. As a consequence of this $\theta$-dependence, the effective photon mass $M_{\text{eff.}}(\theta)$ in (I.4) is, in contrast to the photon mass $M_\gamma$ in (I.1), a function of $\theta$.

In the regime $|q_\parallel^2| \ll m_{\text{dyn.}}^2 \ll |eB|$, it can be shown that for large enough magnetic field and depending on the angle $\theta$, a qualitative change occurs in the Coulomb-like potential $V_1(R, \theta)$; Whereas for $\theta = 0, \pi$ the potential is repulsive, it exhibits a minimum for angles $\theta \in [0, \pi]$ and distances $R \leq 0.005$ fm. The position of this minimum is proportional to $1/\sqrt{B}$ and the depth of the potential at $R_{\text{min}}$ increases with the magnetic field. The exact value of the strong magnetic field will be determined in Sec. V. We interpret the appearance of such a minimum as a possibility for bound state formation in $D = 4$ dimensions. A rigorous proof of the bound state formation in the above potentials $V_1$ and $V_2$ is the subject of a separate investigation and is beyond the scope of this paper.\(^2\)

The organization of the paper is as follows. In Sec. II, a brief review of QED in a strong magnetic field containing some important results from [4] will be presented. In Sec. III, the static potential of QED in a strong magnetic field will be calculated perturbatively by determining the vev of the Wilson loop of a static fermion-antifermion pair in two regimes of the dynamical mass $|q_\parallel^2| \ll m_{\text{dyn.}}^2 \ll |eB|$ and $m_{\text{dyn.}}^2 \ll |q_\parallel^2| \ll |eB|$ in the LLL. In Sec. IV a semi-classical Born approximation will be used to determine the same particle-antiparticle potentials. In Section V, a qualitative analysis of these potentials will be performed and the role played by the angle $\theta$ will be discussed in detail. Sec. VI summarizes our results.

II. QED IN A STRONG MAGNETIC FIELD

In this section we will briefly review the characteristics of fermions and photons in a constant external magnetic field. To this purpose, let us start with the QED Lagrangian density

$$\mathcal{L} = -\frac{1}{4}F_{\mu\nu}F^{\mu\nu} + \bar{\psi} \gamma^\mu (i\partial_\mu + eA_\mu) \psi - m\bar{\psi}\psi, \quad (II.1)$$

where the vector field $A_\mu = a_\mu + A_\mu^{\text{ext.}}$, where $a_\mu$ is an Abelian quantum gauge field, $F_{\mu\nu}$ is the corresponding field strength, and $A_\mu^{\text{ext.}}$ describes an external electromagnetic field. In this paper we will choose the symmetric gauge for $A_\mu^{\text{ext.}}$, i.e.,

$$A_\mu^{\text{ext.}} = \frac{B}{2} (0, x_2, -x_1, 0). \quad (II.2)$$

\(^2\) A nonperturbative analysis of the corresponding Schrödinger equation describing the Nambu-Goldstone modes and arising from a Bethe-Salpeter equation for bound states shows that at least one bound state can be formed in the attractive potential in $D = 4$ dimensions [4] (for more details, see the explanation in the last paragraph of Sec. II).
This leads to a magnetic field in $x_3$ direction. From now on, the longitudinal (0, 3) directions will be denoted by $x_∥$ and the transverse directions (1, 2) by $x_\perp$. Using the Schwinger proper time formalism [9], it is possible to derive the fermion and photon propagator in this gauge. As for the fermion propagator, it is given by

$$S_F(x, y) = \exp \left( \frac{ie}{2} (x - y)^\mu A_\mu^\text{ext.}(x + y) \right) S(x - y)$$

$$= \exp \left( \frac{i e B}{2} \epsilon^{a b x_a y_b} \right) S(x - y), \quad a, b = 1, 2. \quad \text{(II.3)}$$

Here, the first factor containing the external gauge field, $A_\mu^\text{ext.}$, is the Schwinger line integral [9]. The Fourier transform of the translational invariant part $S(x - y)$ reads

$$\tilde{S}(k) = \frac{d}{d s} e^{-ism^2} \exp \left( is \left[ k_\parallel^2 - \frac{k_\perp^2}{e Bs \cot(e Bs)^1} \right] \right) \times \left\{ (m + \gamma_\parallel \cdot k_\parallel) (1 - \gamma_\parallel^2 \tan(e BS)) - \gamma_\perp \cdot k_\perp (1 + \tan^2(e BS)) \right\}, \quad \text{(II.4)}$$

where $k_\parallel = (k_0, k_3)$ and $\gamma_\parallel = (\gamma_0, \gamma_3)$ and $k_\perp = (k_1, k_2)$ and $\gamma_\perp = (\gamma_1, \gamma_2)$. After performing the integral over $s$, $\tilde{S}(k)$ can be decomposed as follows

$$\tilde{S}(k) = i e^{-\frac{k^2}{2|eB|}} \sum_{n=0}^{\infty} (-1)^n \frac{D_n(eB, k)}{k_\parallel^2 - m^2 - 2|eB| n}. \quad \text{(II.5)}$$

with $D_n(eB, k)$ expressed through the generalized Laguerre polynomials $L^\alpha_m$

$$D_n(eB, k) = (\gamma_\parallel \cdot k_\parallel + m) \left\{ 2 \mathcal{O} \left[ L_n (2 \rho) - L_{n-1} (2 \rho) \right] + 4 \gamma_\perp \cdot k_\perp L^1_{n-1} (2 \rho) \right\}. \quad \text{(II.6)}$$

Here, we have introduced $\rho \equiv \frac{k^2}{|eB|}$ and

$$\mathcal{O} \equiv \frac{1}{2} \left( 1 - i \gamma^1 \gamma^2 \text{sign}(eB) \right). \quad \text{(II.7)}$$

Relation (II.5) suggests that in the IR region, with $|k_\parallel|, |k_\perp| \ll \sqrt{|eB|}$, all the higher Landau levels with $n \geq 1$ decouple and only the lowest Landau level (LLL) with $n = 0$ is relevant. In strong magnetic field limit, the full fermion propagator (II.3) can therefore be decomposed into two independent transverse and longitudinal parts [4]

$$S_F(x, y) = S_\parallel(x_\parallel - y_\parallel) P(x_\perp, y_\perp), \quad \text{(II.8a)}$$

with the longitudinal part

$$S_\parallel(x_\parallel - y_\parallel) = \int \frac{d^2 k_\parallel}{(2\pi)^2} e^{i k_\parallel \cdot (x - y)_\parallel} \frac{i \mathcal{O}}{\gamma_\parallel \cdot k_\parallel - m}, \quad \text{(II.8b)}$$

and the transverse part

$$P(x_\perp, y_\perp) = \frac{|eB|}{2\pi} \exp \left( \frac{ie B}{2} \epsilon^{a b} x_a y_b - \frac{|eB|}{4} (x_\perp - y_\perp)^2 \right), \quad a, b = 1, 2. \quad \text{(II.8c)}$$
The photon propagator $D_{\mu\nu}$ of QED in an external constant magnetic field in one-loop approximation with fermions from lowest Landau level (LLL) is calculated explicitly in [4,10]. It is given by

$$iD_{\mu\nu}(q) = \frac{g_{\mu\nu}}{q^2} + \frac{q_{\mu}q_{\nu}}{q^2} + \frac{(g_{\mu\nu} - q_{\mu}q_{\nu}/q^2)}{q^2 + q^2\Pi(q_\perp^2, q_\parallel^2)} - \xi \frac{q_{\mu}q_{\nu}}{(q^2)^2},$$

where $\xi$ is an arbitrary gauge parameter. Since the LLL fermions couple only to the longitudinal (0,3) components of the photon fields, no polarization effects are present in the transverse (1,2) components of $D_{\mu\nu}(q)$. Therefore, the full photon propagator in the LLL approximation is given by the Feynman-like covariant propagator [4]

$$i\tilde{D}_{\mu\nu}(q) = \frac{g_{\mu\nu}}{q^2 + q_\parallel^2 \Pi(q_\parallel^2, q_\perp^2)},$$

with $\Pi(q_\perp^2, q_\parallel^2)$ having the form [11]

$$\Pi(q_\perp^2, q_\parallel^2) = \frac{2\alpha|eB|N_f}{q_\parallel^2}e^{-\frac{q_\parallel^2}{2\pi m_{\text{dyn.}}}}H\left(\frac{q_\parallel^2}{4m_{\text{dyn.}}^2}\right).$$

Here $N_f$ is the number of fermion flavors and $\alpha \equiv \frac{e^2}{\hbar c}$, where $e$ is the running coupling. Further, $H(z)$ in (II.11) is defined by

$$H(z) \equiv \frac{1}{2\sqrt{z(z-1)}} \ln \left(\frac{\sqrt{1-z} + \sqrt{z}}{\sqrt{1-z} - \sqrt{z}}\right) - 1.$$ (II.12)

Expanding this expression for $|q_\parallel^2| \ll m_{\text{dyn.}}^2 \ll |eB|$ and $m_{\text{dyn.}}^2 \ll |q_\parallel^2| \ll |eB|$ leads to

$$\Pi(q_\perp^2, q_\parallel^2) \simeq +\frac{\alpha|eB|N_f}{3\pi m_{\text{dyn.}}^2}e^{-\frac{q_\parallel^2}{2\pi m_{\text{dyn.}}}} \quad \text{for} \quad |q_\parallel^2| \ll m_{\text{dyn.}}^2 \ll |eB|,$$ (II.13)

$$\Pi(q_\perp^2, q_\parallel^2) \simeq -\frac{2\alpha|eB|N_f}{\pi q_\parallel^2}e^{-\frac{q_\parallel^2}{2\pi m_{\text{dyn.}}}} \quad \text{for} \quad m_{\text{dyn.}}^2 \ll |q_\parallel^2| \ll |eB|.$$ (II.14)

In [4], it is shown that the kinematic region mostly responsible for generating the fermion mass is with the dynamical mass, $m_{\text{dyn.}}$, satisfying $m_{\text{dyn.}}^2 \ll |q_\parallel^2| \ll |eB|$. Plugging (II.14) in the full photon propagator (II.10) and assuming that $|q_\perp^2| \ll |eB|$, we get

$$\tilde{D}_{\mu\nu}(q) \approx -\frac{ig_{\mu\nu}}{q^2 - M_\gamma^2}, \quad \text{with} \quad M_\gamma^2 = \frac{2\alpha|eB|N_f}{\pi}. $$ (II.15)

The appearance of a finite photon mass $M_\gamma$ is the result of the dimensional reduction $3 + 1 \rightarrow 1 + 1$ in the presence of a constant magnetic field. This phenomenon can be understood as a reminiscent of the Higgs effect in the $1 + 1$ dimensional Schwinger model, where the photon acquires also a finite mass.

As for the dynamically generated fermion mass $m_{\text{dyn.}}$, it can be determined by solving the corresponding Schwinger-Dyson (SD) equation in the rainbow (ladder) approximation, where the effects of dynamical fermions are neglected. In this approximation, the gauge invariant dynamical mass is shown to have the form [4]

$$m_{\text{dyn.}} = C\sqrt{eB}\exp\left(-\frac{\pi}{2}\left(\frac{\pi}{2\alpha}\right)^{1/2}\right),$$ (II.16)
where the constant $C$ is of order one.\(^3\) In the improved rainbow approximation, however, the expression for $m_{\text{dyn.}}$ takes the following form \(^4\)

\[ m_{\text{dyn.}} = \tilde{C} \sqrt{|eB| F(\alpha)} \exp \left( -\frac{\pi}{\alpha \ln (C_1/\alpha N_f)} \right), \tag{II.17} \]

where $F(\alpha) \simeq (N_f \alpha)^{1/3}$, $C_1 \simeq 1.82 \pm 0.06$ and $\tilde{C} \sim O(1)$.

The dynamical mass, $m_{\text{dyn.}}$, plays the role of energy in the two-dimensional Schrödinger equation

\[ (-\Delta + m_{\text{dyn.}}^2 + V(x)) \Psi(x) = 0, \quad \text{with} \quad \Delta \equiv \frac{\partial^2}{\partial x_3^2} + \frac{\partial^2}{\partial x_4^2}. \tag{II.18} \]

Here, the attractive potential has the form \(^4\)

\[ V(x) = \frac{\alpha |eB|}{\pi} \exp \left( \frac{R^2 |eB|}{2} \right) \text{Ei} \left( -\frac{R^2 |eB|}{2} \right), \tag{II.19} \]

and behaves as

\[ V(x) \simeq -\frac{2\alpha}{\pi} \frac{1}{R^2}, \quad R \to \infty, \]

\[ V(x) \simeq -\frac{\alpha |eB|}{\pi} \left( \gamma_E + \ln \frac{2}{R^2 |eB|} \right), \quad R \to 0, \tag{II.20} \]

where $\gamma_E \simeq 0.577$ is the Euler constant. To determine the long and short range behavior of the potential, the asymptotic behavior of Ei($x$) is used \(^4\). In this context, the problem concerning bound state formation is reduced to finding the spectrum of bound states of the Schrödinger equation (II.18) with the attractive potential (II.19). In \(^4\), it is shown that in $D = 4$ dimensions at least one bound state can be formed. Figure 1 shows the behavior of $V(x)$ for different $B = 10^3, 10^4, 10^5, 10^9$ and $B = 10^{12}$ (from left to right) as a function of $R$.\(^4\) According to this result, whereas for $B < 10^9$ at each given distance

![Figure 1: Potential $V(x)$ from (II.19) of a particle-antiparticle pair for different magnetic fields. According to this result whereas for $B \leq 10^9$ at each given distance the absolute value of the potential increases with increasing the magnetic field, the shape of the potential does not change for $B \geq 10^9$.](image)

\(^3\) The problem of gauge invariance of chiral symmetry breaking induced by the magnetic field found in the ladder QED is investigated in \(^4\).

\(^4\) Note that discussion here is purely qualitative. It is nevertheless possible to give the strength of the magnetic fields in Gauss through the relation $6.8 \times 10^{19} B \approx H$ in Gauss \(^4\). Using this relation the potential $V(R)$ is given in GeV=10\(^9\) eV and the distance $R$ in fm=10\(^{-15}\) m.
the absolute value of the potential increases with increasing the magnetic field, the shape of the potential does not change for \( B \geq 10^9 \).

In the next section we will determine the static Coulomb potential between a fermion-antifermion pair in two aforementioned regimes in the LLL approximation by calculating the vev of the Wilson loop perturbatively. Note that although our method is a perturbative one, our results depend explicitly on \( m_{\text{dyn}} \), which is determined nonperturbatively in the literature [4].

III. THE WILSON LOOP AND THE MODIFIED COULOMB POTENTIAL IN A STRONG MAGNETIC FIELD

In ordinary Quantum Field Theory with no background magnetic field, the Wilson loop appears as one of the most efficient tools for probing the large distance properties of strong coupling QCD. It provides a natural criterion for confinement through the area law. In contrast to QED, where the field lines connecting a pair of opposite charges are allowed to spread, one expects that in QCD the quarks within a hadron are the sources of a chromoelectric flux which is concentrated within narrow tubes connecting the constituents. Since the energy is not allowed to spread, the potential of a quark-antiquark pair \( \langle \bar{q}q \rangle \) will increase with their separation, as long as vacuum polarization effect do not screen their color charge. This picture of confinement can be checked by computing the nonperturbative potential between a static quark-antiquark pair in the path integral formalism.

It is the main purpose of this section to investigate the properties of the Wilson loop concerning the bound state problem of QED in the presence of a strong magnetic field in the LLL approximation. Here, the magnetic field plays the role of a strong catalyst and even the weakest attractive potential between fermions is enough for dynamical mass generation and bound state formation. Before calculating the modified Coulomb potential by determining the vev of the Wilson line of a static fermion-antifermion pair in two regimes of dynamical mass, \( |\mathbf{q}| \ll m_{\text{dyn}} \ll |eB| \) and \( m_{\text{dyn}} \ll |\mathbf{q}| \ll |eB| \), we briefly review the path integral formulation leading to the Coulomb potential between slowly moving particles in ordinary QED. Here, we keep closely on the notations of [16] and the classical review article [8].

Imagine creating a fermion-antifermion pair, \( \bar{\psi}\psi \), at space time point \( x_\mu = 0 \) and adiabatically separate them to a relative distance \( R \). This configuration will be hold for a time \( T \to \infty \). Finally we bring \( \bar{\psi}\psi \) pair back together and let them annihilate. The Euclidean amplitude for this process is the matrix element of the Hamiltonian evolution operator \( e^{-HT} \) between the initial and final states, \( \langle i \rangle \) and \( |f\rangle \), respectively.

\[
\langle i | e^{-HT} | f \rangle. \tag{III.1}
\]

Here, \( \langle i \rangle \) and \( |f\rangle \) represents a \( \bar{\psi}\psi \) pair a distance \( R \) apart and \( H \) is the Hamiltonian (for more details concerning the exact mathematical structure of the initial and final states, \( \langle i \rangle \) and \( |f\rangle \), see [16]). In the path integral representation the matrix element (III.1) can be expressed by

\[
\langle i | e^{-HT} | f \rangle = \frac{\int \mathcal{D}A_\mu \mathcal{D}\bar{\psi}\mathcal{D}\psi \, e^{-S + i \int j_\mu(x) A_\mu(x) d^4x}}{\int \mathcal{D}A_\mu \mathcal{D}\bar{\psi}\mathcal{D}\psi \, e^{-S}}, \tag{III.2}
\]

where we have already skipped the subscript \( E \) for the Euclidean action \( S \). Here, the current \( j_\mu \) should describe the closed worldline \( C \) of the creation and annihilation of \( \bar{\psi}\psi \) pair. For a closed worldline of the
heavy fermions \[ \text{III.2} \] simplifies to \[ 16 \]

\[
\langle i | e^{-HT} | f \rangle = \int \frac{DA_\mu D\psi D\bar{\psi} e^{-S + ie \oint A_\mu(x) dx_\mu}}{DA_\mu D\psi D\bar{\psi} e^{-S}}. \tag{III.3}
\]

Since in a closed path \( |i\rangle \) and \( |f\rangle \) are identical and since the process is static, the Hamiltonian \( H \) is purely potential and the left hand side (l.h.s) of \( \text{III.3} \) is

\[
\langle i | e^{-HT} | f \rangle = e^{-V(R)T}. \tag{III.4}
\]

Here, \( V(R) \) is the fermion-antifermion potential. Taking the logarithm of \( \text{III.3} \) by plugging \( \text{III.4} \) on its l.h.s, it is given by

\[
V(R) = -\lim_{T \to \infty} \frac{1}{T} \ln(W_C[A]), \tag{III.5}
\]

where we have introduced the “loop-correlation” function – the Wilson loop \[ 17, 18, 19 \],

\[
W_C[A] \equiv e^{\oint_C dx_\mu A_\mu(x)}, \tag{III.6}
\]

and used the definition

\[
\langle O \rangle \equiv \int \frac{DA_\mu D\psi D\bar{\psi} \ O e^{-S}}{DA_\mu D\psi D\bar{\psi} e^{-S}}. \tag{III.7}
\]

For \( S \) being the QED action, the Coulomb potential \( V(R) = -\frac{e^2}{4\pi R} \) can be analytically calculated in the quenched approximation, \( i.e. \) when the vacuum polarization effects arising from the presence of dynamical fermions are neglected. To calculate this Coulomb potential, one expands \( \langle W_C[A] \rangle \) in powers of the background field \( A_\mu \), to get

\[
\langle W_C[A] \rangle = (1 + ie \oint_C dx_\mu A_\mu(x) - \frac{e^2}{2} \oint_C \oint_C dx_\mu dy_\nu D_{\mu\nu}(x,y) + \cdots). \tag{III.8}
\]

Here, the second term including only one gauge field does not contribute. As for the other terms, the terms with an odd number of external photon lines does not contribute to the above expansion. This is because of the Furry’s theorem, that holds in ordinary QED in contrary to QED in the presence of external magnetic field \[ 5 \]. Plugging \( \text{III.8} \) in \( \text{III.5} \), the Coulomb potential is given by

\[
V(R) = \lim_{T \to \infty} \frac{1}{T} \ln \left( 1 - \frac{e^2}{2} \oint_C \oint_C dx_\mu dy_\nu D_{\mu\nu}(x,y) + \cdots \right)
\]

\[
= \lim_{T \to \infty} \frac{e^2}{2T} \oint_C \oint_C dx_\mu dy_\nu D_{\mu\nu}(x,y) + O(e^3), \tag{III.9}
\]

where we have expanded the \( \ln(1 - \cdots) \) for weak coupling constant \( e \). The integrand is the photon propagator in the coordinate space

\[
D_{\mu\nu}(x,y) \equiv \langle A_\mu(x)A_\nu(y) \rangle = \frac{\delta_{\mu\nu}}{4\pi^2(x-y)^2}. \tag{III.10}
\]

\[ 5 \] The phenomenon of photon splitting \( \gamma \rightarrow 2\gamma \) in the presence of external magnetic field \[ 20 \] is the best counterexample for the validity of Furry’s theorem for QED in external magnetic field.
To compute the double integral (III.9), one chooses a rectangular contour. Because, in the Euclidean space, the integrand (III.10) is proportional to $\delta_{\mu\nu}$, the double integral receives a contribution when $x$ and $y$ are located on the segments of integration contour which are parallel to each other. The double integral therefore reduces to

$$V(R) = \lim_{T \to \infty} -\frac{e^2}{T} \int_0^T dT_1 \int_0^T dT_2 \frac{1}{4\pi^2 \left[ R^2 + (T_1 - T_2)^2 \right]}.$$  \hspace{1cm} (III.11)

Here $R \equiv |x - y|$. Performing now the double integration, one arrives first at [16]

$$V(R) = \lim_{T \to \infty} -\frac{e^2}{2\pi^2} \left( \frac{1}{R} \arctan \frac{T}{R} + \frac{1}{2T} \ln \left( 1 + \frac{T^2}{R^2} \right) \right),$$  \hspace{1cm} (III.12)

and then after taking the limit $T \to \infty$, at the Coulomb potential of a fermion-antifermion pair

$$V(R) = \frac{\alpha}{R}.$$  \hspace{1cm} (III.13)

After this brief excursion, let us now turn back to our original problem of computing the modified Coulomb potential of QED in the presence of external strong magnetic field. In the regime of lowest Landau level (LLL), the full photon propagator $\tilde{D}_{\mu\nu}$ in the momentum space is given by (II.10), where $\Pi(q_\parallel^2, q_\perp^2)$ is defined in (II.11). It is indeed a very difficult task to calculate the potential of static fermion-antifermion pair for full photon propagator (II.10). We will therefore consider only two different regimes of dynamical mass $q_\parallel^2 \ll m_{\text{dyn}}^2 \ll |eB|$ and $m_{\text{dyn}}^2 \ll q_\parallel^2 \ll |eB|$, with $\Pi(q_\parallel^2, q_\perp^2)$ given in (II.13) and (II.14), respectively, and will calculate the modified Coulomb potential $V(x)$ in these two regimes.

### A. Modified Coulomb potential in $|q_\parallel^2| \ll m_{\text{dyn}}^2 \ll |eB|$ regime

Substituting (II.13) with $N_f = 1$ in (II.10) the full photon propagator in this regime reads

$$\tilde{D}_{\mu\nu}(q) = -i g_{\mu\nu} \frac{q_\parallel^2 + m_{\text{dyn}}^2}{q^2 + \frac{a|eB|}{3\pi m_{\text{dyn}}^2} q_\parallel^2 \exp \left( -\frac{q_\perp^2}{2|eB|} \right)}.$$  \hspace{1cm} (III.14)

To calculate the Coulomb potential by (III.9), we need the LLL photon propagator in the coordinate space, i.e. the Fourier transformed of (III.14)

$$\tilde{D}_{\mu\nu}(x) = -i g_{\mu\nu} \int \frac{d^4q}{(2\pi)^4} \frac{e^{iqx}}{q^2 + \frac{a|eB|}{3\pi m_{\text{dyn}}^2} q_\parallel^2 \exp \left( -\frac{q_\perp^2}{2|eB|} \right)}.$$  \hspace{1cm} (III.15)
After a lengthy but straightforward calculation of the above integral over \( q \) (see Appendix A for more details), we arrive at the LLL photon propagator in the coordinate space

\[
\bar{D}_{\mu\nu}(R, \theta, T) = \frac{2|\mu|}{4\pi a_1} \left[ \left( 1 + \frac{\gamma}{a_1} \right) - \frac{4a_2 + \gamma R^2 \sin^2 \theta}{2\beta a_1^2} + \frac{3a_2 R^2 \sin^2 \theta}{2\beta^2 a_1^4} \right] \\
+ \frac{4\gamma^2}{a_1^2} \left( 1 - \frac{3R^2 \sin^2 \theta}{2\beta a_1} + \frac{3R^4 \sin^4 \theta}{8\beta^2 a_1^2} \right) \\
- \frac{12\gamma a_2}{\beta a_1^3} \left( 2 - \frac{2}{\beta a_1} \left( 2R^2 \sin^2 \theta + \frac{a_2}{\gamma} \right) + \frac{5}{4\beta^2 a_1^2} \left( R^4 \sin^4 \theta + \frac{4a_2 R^2 \sin^2 \theta}{\gamma} - \frac{15a_2 R^4 \sin^4 \theta}{8\gamma R^3 a_1^3} \right) \right). \\
\]  

(III.16)

Here,

\[
\beta^{-1} \equiv 4 \left( 1 + \frac{\alpha |eB|}{3\pi m_{\text{dyn.}}^2} \right) \quad \text{and} \quad \gamma(\alpha) \equiv \frac{2\alpha}{3\pi m_{\text{dyn.}}^2},
\]  

(III.17)

are constant c-numbers, and \( a_i = a_i(R, \theta, T), \ i = 1, 2 \) are defined by

\[
a_1(R, \theta, T) \equiv T^2 + R^2 f^2(\alpha, \theta), \quad \text{with} \quad f^2(\alpha, \theta) \equiv 1 + \frac{|eB|}{2} \sin^2 \theta, \\
a_2(R, \theta, T) \equiv \beta \gamma \left( T^2 + R^2 \cos^2 \theta \right).
\]  

(III.18)

In all the above expressions \( R \equiv |x| \) is the distance between the static fermion and antifermion pair, \( \theta \) is the angle between the particle-antiparticle axis and the direction of the magnetic field \( B \), \( i.e. \) the \( x_3 \) direction, and \( T \equiv ix_0 \) is the Euclidean time. Note that here, to determine the LLL photon propagator, we have to use of the approximation \( q_\parallel^2 \ll |eB| \), which is valid in the regime of strong magnetic field.

To determine the static potential between the \( \bar{\psi}\psi \) pair, we have to calculate the double integral [see (III.11) leading to the expression of the ordinary Coulomb potential]

\[
V(R, \theta) = \lim_{T \to \infty} -\frac{e^2}{T} \int_0^T dT_1 \int_0^T dT_2 \bar{D}_{00}(R, \theta, T_1 - T_2),
\]  

(III.19)

which can be easily simplified to

\[
V(R, \theta) = -2e^2 \int_0^\infty dT \bar{D}_{00}(R, \theta, T).
\]  

(III.20)

Using now the definition of \( \bar{D}_{\mu\nu}(R, \theta, T) \) in (III.16), and performing the integration over \( T \), the modified Coulomb potential in the regime \( |q_\parallel^2| \ll m_{\text{dyn.}}^2 \ll |eB| \) can be given by

\[
V(R, \theta) = -\frac{\alpha}{R} \left( A_1(\alpha, \theta) - \frac{\gamma A_2(\alpha, \theta)}{R^2} + \frac{\gamma^2 A_3(\alpha, \theta)}{R^4} \right),
\]  

(III.21)
with
\[ A_1(\alpha, \theta) \equiv \frac{1}{f}, \]
\[ A_2(\alpha, \theta) \equiv \frac{-1}{4f^3} \left( 1 - \frac{3\cos^2 \theta}{f^2} - \frac{3\sin^2 \theta}{8f^2} + \frac{15\sin^2 \theta \cos^2 \theta}{8f^4} \right), \]
\[ A_3(\alpha, \theta) \equiv \frac{9}{16f^5} \left( 1 - \frac{5\sin^2 \theta}{4f^2} + \frac{35\sin^4 \theta}{128\beta f^4} \right) \]
\[ - \frac{15\cos^2 \theta}{8f^7} \left( 3 - \frac{7}{4\beta f^2} (2\beta \cos^2 \theta + 3\sin^2 \theta) + \frac{63\sin^2 \theta}{8^2 f^4} \left( \beta \cos^2 \theta + \frac{3\sin^2 \theta}{16} \right) - \frac{693\cos^2 \theta \sin^4 \theta}{256\beta^2 f^6} \right) \]
\[ - \frac{3}{16|eB|f^5\gamma \beta} \left( 1 - \frac{5}{4\beta f^2} (4\beta \cos^2 \theta + \sin^2 \theta) + \frac{35\sin^2 \theta}{4\beta f^4} \left( \beta \cos^2 \theta + \frac{\sin^2 \theta}{32} \right) - \frac{315\cos^2 \theta \sin^4 \theta}{128\beta^2 f^6} \right). \]

(III.22)

In Sec. V we will present a qualitative analysis of the above potential emphasizing the role played by the angle \( \theta \) in a possible bound state formation.

**B. Modified Coulomb potential in \( m_{\text{dyn.}}^2 \ll |q|^2 \ll |eB| \) regime**

To compute the inter-particle potential in this regime, we substitute (II.14) in (II.10). For \( N_f = 1 \), the full photon propagator in the coordinate space reads
\[ \tilde{D}_{\mu\nu}(x) = -ig_{\mu\nu} \int \frac{d^4q}{(2\pi)^4} \frac{e^{iqx}}{q^2 - \frac{2\alpha|eB|}{\pi} \exp\left( -\frac{|q|^2}{2|eB|} \right)}. \]

(III.23)

The integration over \( q \) can be performed using the approximation \( \frac{|q|^2}{2|eB|} \ll 1 \) which is valid in the regime of LLL dominance. After a straightforward calculation (see Appendix B for more details), the propagator is given by
\[ \tilde{D}_{\mu\nu}(R, \theta, T) = \frac{\delta_{\mu\nu}}{4\pi^2(1 - \frac{\alpha}{\pi}) \sqrt{T^2 + R^2g^2(\theta)}} K_1 \left( \zeta \sqrt{T^2 + R^2g^2(\theta)} \right), \]

(III.24)

where
\[ \zeta \equiv \sqrt{\frac{2\alpha|eB|}{\pi}}, \quad \text{and} \quad g^2(\theta) \equiv \cos^2 \theta + \frac{\sin^2 \theta}{1 - \frac{\alpha}{\pi}}. \]

(III.25)

The fermion-antifermion potential in this regime is then calculated using the expression (III.19) or equivalently (III.20) and reads
\[ V(R, \theta) = -\frac{e^2\zeta}{2\pi^2(1 - \frac{\alpha}{\pi})} \int_0^\infty dT \frac{1}{\sqrt{T^2 + R^2g^2(\theta)}} K_1 \left( \sqrt{T^2 + R^2g^2(\theta)} \right). \]

(III.26)

To evaluate the integral we make use of
\[ \int_0^\infty d\tau \frac{\tau^{2\mu+1}}{\sqrt{\tau^2 + z^2}} K_\nu \left( \zeta \sqrt{\tau^2 + z^2} \right) = \frac{2\mu\Gamma(\mu + 1)}{\zeta^{\mu+1}z^{\nu-\mu-1}K_{\nu-\mu-1}(\zeta z)}, \quad \zeta > 1, \quad \text{Re}(\mu) > -1. \]

(III.27)

Choosing \( \tau = T, \quad z = Rg(\theta), \quad \nu = 1 \) and \( \mu = -\frac{1}{2} \), we arrive at
\[ V(R, \theta) = -\frac{\zeta g(\theta)}{(1 - \frac{\alpha}{\pi}) R} e^{-\zeta g(\theta) R}. \]

(III.28)
Here we have used $K_{\frac{1}{2}}(x) = \sqrt{\frac{\pi}{2x}}e^{-x}$ and $\Gamma\left(\frac{1}{2}\right) = \sqrt{\pi}$. Apart from its $\theta$ dependence our result is comparable with (I.1) from [7].

The potential (III.28) is indeed comparable with the ordinary attractive Yukawa potential

$$V_{\text{Yukawa}}(R) = -\frac{\alpha}{R}e^{-mR}, \quad (\text{III.29})$$

where $\alpha \to \frac{\alpha}{(1-\frac{\alpha}{\pi})g(\theta)}$ and the effective photon mass $m \to M_{\text{eff}}(\theta) \equiv \zeta g(\theta)$. This result is also in agreement with the general result about the massive photons in a strong magnetic fields in the LLL approximation. As we have seen in Sec. II, in the regime $m_{\text{dyn}}^2 \ll |q_\parallel^2| \ll |eB|$, the 3 + 1 dimensional QED in the LLL approximation is reduced to a 1 + 1 dimensional Schwinger model where the photon acquires a finite mass $M_\gamma = \sqrt{\frac{2\alpha|eB|N_f}{\pi}}$, with $N_f$ the number of flavors [see (II.15) for more details]. For $N_f = 1$, we have $M_\gamma = \zeta$. Thus the effective photon mass in this regime is given by $M_{\text{eff}} = M_\gamma g(\theta)$ and depends explicitly on the angle $\theta$ between the particle axis and the direction of the external magnetic field. Figure 2 shows the $\theta$-dependence of $g(\theta)$ which is understood to be the ratio $\frac{M_{\text{eff}}}{M_\gamma}$. For all values of $\theta \in [0, \pi]$ the effective mass $M_{\text{eff}}$ and the aforementioned photon mass $M_\gamma$ are almost equal. Here $\alpha$ is fixed to be $\alpha = 1/137$. A qualitative analysis of the potential (III.28) emphasizing the role played by the angle $\theta$ will be presented in Sec. V.

![FIG. 2: The ratio $\frac{M_{\text{eff}}}{M_\gamma} = g(\theta)$ for $\theta \in [0, \pi]$ in the regime $m_{\text{dyn}}^2 \ll |q_\parallel^2| \ll |eB|$ of LLL dominance.](image)

In Sec. IV we will use the Born approximation to determine the static Coulomb potential in two regimes of dynamical mass in the LLL approximation. Eventually we will study the behavior of the potentials (III.21) and (III.26) as a function of the angle $\theta$ for two limits of large and small distances.

**IV. BORN APPROXIMATION AND THE STATIC COULOMB POTENTIAL IN A STRONG MAGNETIC FIELD**

In the nonrelativistic quantum mechanics the relation between the scattering amplitude $\mathcal{M}$ and the potential is given by the Born approximation

$$\langle p'|i\mathcal{M}|p\rangle = -iV(q)(2\pi)\delta(E_{p'} - E_p), \quad (\text{IV.1})$$

where $p$ ($E_p$) and $p'$ ($E_{p'}$) are the momenta (energy) of the incoming and outgoing particles, respectively, and $q = p' - p$. For ordinary QED with no background magnetic field, for instance, the amplitude of a
particle-antiparticle scattering is given by \[ i\mathcal{M} \sim -\frac{i e^2}{|\mathbf{p} - \mathbf{p}'|^2}. \] (IV.2)

Comparing with (IV.1), the attractive (classical) Coulomb potential \( V(q) \) is thus given by

\[
V(q) = -\frac{e^2}{|q|^2}, \quad \text{with} \quad |q| \equiv |\mathbf{p} - \mathbf{p}'|. \tag{IV.3}
\]

After a Fourier transformation into the coordinate space, the same potential reads

\[
V(x) = \int \frac{d^3q}{(2\pi)^3} V(q)e^{iq\cdot x} = -\frac{\alpha}{R}, \tag{IV.4}
\]

where \( R \equiv |x| \). Furthermore, to include the quantum correction into the result, the modified Coulomb potential can be calculated from

\[
V(x) = -\int \frac{d^3q}{(2\pi)^3} e^{iq\cdot x} \frac{e^2}{q^2(1 - \Pi(q^2))}, \tag{IV.5}
\]

where \( \Pi(q) \) in the ordinary QED is defined by the vacuum polarization tensor

\[
\Pi_{\mu\nu}(q) = (q^2 g^{\mu\nu} - q^\mu q^\nu) \Pi(q^2), \tag{IV.6}
\]

and is given by

\[
\Pi(q^2) = -\frac{2\alpha}{\pi} \int_0^1 dx x(1-x) \log \left( \frac{m^2}{m^2 - x(1-x)q^2} \right). \tag{IV.7}
\]

Choosing \( q_0 = 0 \) and plugging this relation into (IV.5), after some straightforward calculation \[21\], one arrives at the so called \textit{Uehling potential}

\[
V(R) = -\frac{\alpha}{r} \left( 1 + \frac{\alpha}{4\pi} \frac{e^{-2mR}}{(mR)^{3/2}} + \cdots \right). \tag{IV.8}
\]

In this section, we will use the above method to determine the potential of QED in a strong magnetic field in two regimes of dynamical mass \( |q^2_\parallel| \ll m^2_{\text{dy}n.} \ll |eB| \) and \( m^2_{\text{dy}n.} \ll |q^2_\perp| \ll |eB| \) separately. We will show that our results coincide with (III.21)-(III.22) in the regime \( |q^2_\parallel| \ll m^2_{\text{dy}n.} \ll |eB| \) and with (III.26) in the regime \( m^2_{\text{dy}n.} \ll |q^2_\parallel| \ll |eB| \).

### A. Modified Coulomb potential in \( |q^2_\parallel| \ll m^2_{\text{dy}n.} \ll |eB| \) regime

We will start using the relation (IV.5) where \( \Pi(q) \) in this regime is given by (II.13). The modified Coulomb potential in this regime is therefore given by

\[
V(x) = -e^2 \int \frac{d^3q}{(2\pi)^3} \frac{e^{-iq\cdot x}}{q^2 + \frac{e^2B}{2} q^2_\parallel e^{-\frac{q^2_\perp}{2m_{\text{dy}n.}^2}}}, \tag{IV.9}
\]

where we set \( q_0 = 0 \), and the factor \( \gamma \equiv \frac{\alpha|eB|}{3\pi m_{\text{dy}n.}^2} \) is defined in (III.17). The 3-dimensional integral over \( q \) can be performed by making use of the same methods as was shown in Appendix A. The main steps
of the calculations are as follows. First using the relation (A.2) and (A.8), we write the integrand in the form
\[
V(x) = -e^2 \int_0^\infty ds \int \frac{dq_1 dq_3 dq_4}{(2\pi)^3} e^{-i(q_3 R \cos \theta + q_1 R \sin \theta \cos(\varphi - \varphi'))} \exp \left( -s \left( q_1^2 + q_3^2 + \frac{\gamma eB}{2} q_3^2 e^{-\frac{s q_3^2}{2|eB|}} \right) \right),
\]
where \( \theta \) is the angle between the particle-antiparticle axis and the external magnetic field. The integration over \( \varphi' \) an \( q_3 \) can be performed using (A.10) and (A.12), respectively. We arrive therefore at
\[
V(x) = -e^2 \int_0^\infty ds \sqrt{\frac{\pi}{s}} \int \frac{dq_1 dq_3}{(2\pi)^2} J_0(q_1 R \sin \theta) e^{-s q_1^2} e^{-\frac{\gamma^2 e^2 B^2}{4s}},
\]
where we have introduced
\[
s' \equiv s \left( 1 + \frac{\gamma eB}{2} e^{-\frac{s q_3^2}{2|eB|}} \right),
\]
to simplify our notations. At this stage, to perform the integration over \( q_1 \) and eventually over \( s \), one can use the approximation \( |q_1^2| \ll |eB| \), which is valid in the LLL approximation. The factors \( \frac{1}{s'} \) and \( \frac{1}{\sqrt{s'}} \) are therefore given by
\[
\frac{1}{s'} \approx \frac{2}{s \xi} \left( 1 + \frac{\gamma}{2s} q_1^2 + \left( \frac{\gamma^2}{4s^2} - \frac{\gamma}{8|eB|s} \right) q_1^4 \right),
\]
\[
\frac{1}{\sqrt{s'}} \approx \sqrt{\frac{2}{s \xi}} \left( 1 + \frac{\gamma}{4s} q_1^2 + \left( \frac{3\gamma^2}{32s^2} - \frac{\gamma}{16|eB|s} \right) q_1^4 \right),
\]
where \( \xi \equiv (2 + \gamma|eB|) \). Using these expressions, the potential is given by
\[
V(x) = -e^2 \int_0^\infty ds \sqrt{\frac{2\pi}{s \xi}} \int \frac{dq_1 dq_3}{(2\pi)^2} e^{-s q_1^2} e^{-\frac{b_1}{2s} \frac{1}{2|eB|}} J_0(q_1 R \sin \theta)
\times \left\{ 1 + \frac{\gamma q_1^2}{4s} \left( 1 - \frac{b_1}{s} \right) q_1^4 \left[ \frac{\gamma^2}{16s^2} \left( \frac{3}{2} - \frac{3b_1}{s} + \frac{b_1^2}{2s^2} \right) - \frac{\gamma}{16s|eB|} \left( 1 - \frac{b_1}{s} \right) \right] \right\},
\]
where \( b_1 \equiv R^2 \cos^2 \theta \). The result is similar to (A.16) and indeed we have used the same approximation which was done in (A.15) and led to (A.16). Using now the integrals \( I_i, i = 1, 2, 3 \) from (A.21)-(A.23), (IV.14) can be written as
\[
V(x) = -e^2 \int_0^\infty ds \sqrt{\frac{2\pi}{s \xi}} e^{-\frac{b_1}{2s} \frac{1}{2|eB|}} \times \left\{ I_1 + \frac{\gamma q_1^2}{4s} \left( 1 - \frac{b_1}{s} \right) I_2 + q_1^4 \left[ \frac{\gamma^2}{16s^2} \left( \frac{3}{2} - \frac{3b_1}{s} + \frac{b_1^2}{2s^2} \right) - \frac{\gamma}{16s|eB|} \left( 1 - \frac{b_1}{s} \right) \right] I_3 \right\}.
\]
Here, the integration over \( s \) can be performed using (A.25). After replacing
\[
R^2 \sin^2 \theta + \frac{2R^2 \cos^2 \theta}{\xi} \rightarrow 4\beta R^2 f^2(\theta),
\]
(IV.16)
where $\beta \equiv (2\xi)^{-1}$ and $f^2(\alpha, \theta)$ are defined in (III.17) and (III.18), we arrive at the same potential (III.21)-(III.22). The potential has therefore the general form

$$V(R, \theta) = -\frac{\alpha}{R} \left( A_1(\alpha, \theta) - \frac{\gamma A_2(\alpha, \theta)}{R^2} + \frac{\gamma^2 A_3(\alpha, \theta)}{R^4} \right),$$

with $A_i, i = 1, 2, 3$ from (III.22).

### B. Modified Coulomb potential in $m_{\text{dyn.}}^2 \ll |q_\parallel^2| \ll |eB|$ regime

Starting from (IV.5) and plugging $\Pi(q)$ corresponding to the relevant regime $m_{\text{dyn.}}^2 \ll |q_\parallel^2| \ll |eB|$ from (II.14) and choosing $q_0 = 0$, we arrive first at

$$V(x) = -e^2 \int_0^\infty ds \int dq_1 dq_3 d\varphi' \frac{e^{-i q_1 R \sin \theta \cos(\varphi - \varphi') + q_3 R \cos \theta}}{(2\pi)^3} \frac{e^{-i q \cdot x}}{q^2 + \zeta^2 e^{-\frac{q_\parallel^2}{2|eB|}}}, \quad (IV.17)$$

where $\zeta \equiv \sqrt{\frac{2\alpha |eB|}{\pi}}$ is already defined in (III.25). To perform the three dimensional integral over $q$, we will use the same methods described in Appendix B, to evaluate the full photon propagator in the coordinate space. First using Schwinger’s parametrization technique (II.2), the potential reads

$$V(x) = -e^2 \int_0^\infty ds \int dq_1 dq_3 d\varphi' \frac{e^{-i q_1 R \sin \theta \cos(\varphi - \varphi') + q_3 R \cos \theta}}{(2\pi)^3} \frac{e^{-i q \cdot x}}{q^2 + \zeta^2 e^{-\frac{q_\parallel^2}{2|eB|}}}, \quad (IV.18)$$

where we have used (A.8) to bring $q \cdot x$ in a useful form. Now integrating over $\varphi'$ and $q_3$ using (A.10) and (A.12), we arrive at

$$V(x) = -e^2 \int_0^\infty ds \sqrt{\frac{\pi}{s}} \int dq_1 \frac{e^{-\frac{R^2 \cos^2 \theta}{4s}}}{(2\pi)^2} J_0 (q_1 R \sin \theta) e^{-s q_1^2} e^{-s(1-\frac{\alpha}{\pi})q_\perp^2}, \quad (IV.19)$$

where we have used the IR approximation $|q|^2 \ll |eB|$ relevant in the LLL regime

$$e^{-s \left( q_\perp^2 + \zeta^2 \exp(-\frac{q_\parallel^2}{2|eB|}) \right)} \approx e^{-s \zeta^2} e^{-s(1-\frac{\alpha}{\pi})q_\perp^2}. $$

Next, using (B.10) the integration over $q_\perp$ can be performed. The potential is therefore given by

$$V(x) = -\frac{e^2 \sqrt{\pi}}{8\pi^2 \left( 1 - \frac{\alpha}{\pi} \right)} \int_0^\infty ds \frac{e^{-\frac{R^2}{4s} \sin^2 \theta}}{s^2} e^{-s \zeta^2}, \quad \text{with} \quad g^2(\theta) = \cos^2 \theta + \frac{\sin^2 \theta}{\left( 1 - \frac{\alpha}{\pi} \right)}.$$

The $\theta$-dependent function $g(\theta)$ is defined already in (III.25). Finally defining a new variable $s' = \zeta^2 s$, and using (B.13) the potential $V(x)$ in the $m_{\text{dyn.}}^2 \ll |q_\parallel^2| \ll |eB|$ in the LLL dominance can be calculated and reads

$$V(R, \theta) = -\frac{\alpha}{(1 - \frac{\alpha}{\pi})g(\theta)R} e^{-\zeta g(\theta) R},$$

which is the same potential as (III.28) which was found using the Wilson-loop technique.
V. A QUALITATIVE ANALYSIS OF MODIFIED COULOMB POTENTIALS IN THE LLL

In this section we will consider the potential (III.22) and (III.28)

\[ V_1(R, \theta) = \frac{\alpha}{R} \left( A_1(\alpha, \theta) - \frac{\gamma A_2(\alpha, \theta)}{R^2} + \frac{\gamma^2 A_3(\alpha, \theta)}{R^4} \right), \]

\[ V_2(R, \theta) = -\frac{\alpha}{(1 - \frac{\alpha}{\pi}) g(\theta) R} e^{-\zeta g(\theta) R}, \]

in the first \(|q^2_\parallel| \ll m^2_\text{dym.} \ll |eB|\), and the second \(m^2_\text{dym.} \ll |q^2_\parallel| \ll |eB|\) LLL regimes, respectively. We will eventually compare these potentials with the modified Coulomb potential (11).

As for \(V_1(R, \theta)\), Figure 3 shows this potential for different choices of the magnetic field \(B = 10^5, 10^6, 10^7, 10^9\) (from right to left) and different \(\theta = 0, \pi/3, 2\pi/3, \pi\).

FIG. 3: Potential \(V_1(R, \theta)\) for different \(B\) and \(\theta\). No qualitative changes occurs by varying the angle \(\theta\).

According to this result, for \(R \to 0\) the potential falls more rapidly to \(-\infty\) the smaller the magnetic field is. Although the scales in which the potential \(V_1\) is plotted for \(\theta = 0, \pi\) are different from the scales in which it is plotted for \(\theta = \pi/3, 2\pi/3\), but their shapes are almost the same, i.e. no qualitative changes occurs by varying the angle \(\theta\). This situation changes by neglecting the coefficient \(\gamma^2 A_3\) comparing with \(A_1\) and \(\gamma A_2\) in \(V_1(R, \theta)\). Figure 4 shows the behavior of the coefficients \(A_1\), \(\gamma A_2\) and \(\gamma^2 A_3\) of the potential \(V_1\) as functions of the angle \(\theta\) for different magnetic fields \(B = 10^2, 10^5, 10^7\) and \(B = 10^9\). Choosing \(\alpha = 1/137\), it turns out that the coefficients \(A_1\), \(\gamma A_2\) and \(\gamma^2 A_3\) are positive \(\forall \theta \in [0, \pi]\) and for any choice of constant magnetic field \(B\). However, as it is shown in Figure 3, \(A_3\) decreases rapidly with increasing magnetic field. Whereas for \(B = 10^2\) two coefficients \(A_1\), \(\gamma A_2\) and \(\gamma^2 A_3\) are comparable, for
$B = 10^{5}$, $\gamma A_3$ is $10^4$ times smaller than $A_1$, and for $B = 10^{9}$ this difference is $\sim 13$ order of magnitude. We conclude therefore that for strong magnetic field $B \geq 10^{5}$, the coefficient $\gamma A_3$ in $V_1(R, \theta)$ is negligible comparing with $A_1$ and $\gamma A_2$. Thus for $B \geq 10^{5}$ the potential $V_1(R, \theta)$ can be replaced by

$$V_3(R, \theta) = -\frac{\alpha}{R} \left( A_1(\alpha, \theta) - \frac{\gamma A_2(\alpha, \theta)}{R^2} \right),$$

which has its minimum at

$$R_{\text{min}}(B, \theta) = \sqrt{\frac{3 \gamma A_2}{A_1}}.$$  \hspace{1cm} (V.2)

Figure 5 shows $V_3(R, \theta)$ for different choices of the magnetic field $B = 10^{5}, 10^{6}, 10^{7}$ and $10^{9}$ (from right to left) and different $\theta = 0, \pi/3, \pi/2, 2\pi/3, \pi$. Whereas for $\theta = 0, \pi$ the potential is repulsive, it exhibits a minimum for angles $\theta \in [0, \pi]$ and distances $R \leq 0.005$ fm. The depth of the potential at $R_{\text{min}}$ increases with the magnetic field. We interpret this effect as a possibility for bound state formation. The answer to the question concerning the existence and the number of bound states in the potential $V_3$ is beyond the scope of this paper.
In Figure 6 the behavior of $R_{\text{min}}$ from $V(R, \theta)$ for different $\theta$ is studied. As it turns out, for different $\theta$, the position of the minimum of the potential is proportional to $1/\sqrt{B}$.

FIG. 5: Potential $V_3(R, \theta)$ for different $B$ and $\theta$. Bound states can be formed for $\theta \in [0, \pi]$ and for strong magnetic fields $B \geq 10^5$ in the regime $R \leq 0.005 \text{ fm}$. The depth of the potential at $R_{\text{min}}$ increases with the magnetic field.

FIG. 6: Behavior of the minimum of the potential $V_3$ as a function of $10^7 \leq B \leq 10^{16}$ for different $0 < \theta \leq \pi/2$. For $\pi/2 \leq \theta < \pi$, $R_{\text{min}}$ shows a symmetry in changing $\theta \rightarrow \theta + \pi/2$ (see the 3-dimensional figure on the r.h.s.).
FIG. 7: Potential $V_2(R, \theta)$ for different $B$ and $\theta$. No qualitative changes occur by varying the angle $\theta$. This potential is comparable with the potential (I.1) from [7] in the scaling regime.

Let us now consider the potential $V_2(R, \theta)$ in the second regime $m_{\text{dyn}}^2 \ll |q_\parallel|^2 \ll |eB|$ of LLL. Figure 7 shows its behavior for different magnetic field $B$ and angle $\theta$. Again no qualitative changes occur by varying the angle $\theta$. As it is pointed out in the introduction, this Yukawa-like potential is comparable with the potential (I.1) from [7] in the scaling regime.

VI. SUMMARY

In this paper the static potential of QED is calculated in the presence of a strong but constant magnetic field using two different methods. First a perturbative Wilson loop calculation is performed for two different regimes of dynamical mass $|q_\parallel|^2 \ll m_{\text{dyn}}^2 \ll |eB|$, and $m_{\text{dyn}}^2 \ll |q_\parallel|^2 \ll |eB|$ in the lowest Landau level (LLL). The resulting potential is then compared with the potential arising from a modified Born approximation. The results coincide. Comparing with the recently calculated potential of point like charges in [7], our potential shows a novel dependence on the angle $\theta$ between the particle-antiparticle axis and the direction of the magnetic field. A qualitative analysis of these modified potentials is performed in the previous Sec. V. As for the potential (III.22) from the first regime $|q_\parallel|^2 \ll m_{\text{dyn}}^2 \ll |eB|$, it turns out that for strong magnetic field $B \geq 10^5$, the coefficient of the $R^{-5}$ term, i.e. $\gamma_2 A_3$, is negligible comparing to the both other coefficients $A_1$ and $\gamma A_2$ from the expected Coulombian $R^{-1}$ and the additional $R^{-3}$ terms. Keeping only these two coefficients, a qualitative change occurs in the Coulomb-like potential which depends on the angle $\theta$; Whereas for $\theta = 0, \pi$ the potential is repulsive, it exhibits a minimum
for angles $\theta \in ]0, \pi[$ and distances $R \leq 0.005$ fm. The depth of the potential at $R_{\text{min}}$ increases with the magnetic field and the position of the minimum is proportional to $1/\sqrt{B}$. We interpret this effect as a possibility for bound state formation. A rigorous proof of the existence and the number of bound states in the above potential is the subject of future investigations.

As for the potential (III.28) of the second regime $m_{\text{dyn.}}^2 \ll |q_\parallel^2| \ll |eB|$, it is comparable with a screened Yukawa potential. It is well-known that in this regime the photon acquires a finite mass proportional to $\sqrt{|eB|}$. According to our result, the photon receives also a modified effective mass depending on the angle $\theta$ between the particle axis and the direction of the magnetic field. But, this dependence is indeed negligible for fixed $\alpha = 1/137$. This result is in good agreement with the result recently found in [7].

It would be interesting to study the renormalization group (RG) improvement of these potentials, as they both depend on the coupling constant $e$, which is taken to be a bare parameter in our calculations. Using the RG improved potential it is possible, according to [8], to determine the Callan-Symanzik $\beta$-function of QED in the presence of strong magnetic field in the LLL approximation.

Acknowledgments

The authors thank F. Ardalan and H. Arfaei for useful discussions. N.S. thanks in particular the referee of the paper for valuable hints concerning the potential $V(x)$ from [4].

APPENDIX A: THE LLL PHOTON PROPAGATOR IN $|q_\parallel^2| \ll m_{\text{dyn.}}^2 \ll |eB|$ REGIME

In this section we will perform the integration over $q$ in (III.15) to determine the full LLL photon propagator in $m_{\text{dyn.}}^2 \ll |q_\parallel^2| \ll |eB|$ regime (III.10). To start, let us give the integral (III.15) in the Euclidean space

$$\tilde{D}_{\mu\nu}(x) = \delta^{\parallel}_{\mu\nu} \int \frac{d^4q}{(2\pi)^4} \frac{e^{-i(q_4x_4 + q\cdot x)}}{q^2 + \frac{\gamma(\alpha)|eB|}{2} (q_3^2 + q_4^2) \exp(-\frac{q_\parallel^2}{2|eB|})},$$

(A.1)

where $\gamma(\alpha) \equiv \frac{2\alpha}{3\pi m_{\text{dyn.}}^2}$. Here, the Euclidean coordinates $x_0 = -ix_4$ as well as $q_0 = -iq_4$. We have further used the notations $q = (q_1, q_2, q_3)$ and $x = (x_1, x_2, x_3)$. The scalar product is defined therefore by $q \cdot x = \sum_{i=1}^3 q_i x_i$. Using the Schwinger parametrization technique

$$\int_0^\infty ds \ e^{-as} = \frac{1}{a},$$

(A.2)

the above expression (A.1) can be given by

$$\tilde{D}_{\mu\nu}(x) = \delta^{\parallel}_{\mu\nu} \int_0^\infty ds \int \frac{d^4q}{(2\pi)^4} e^{-i(q_4x_4 + q\cdot x)} \exp(-s \left( q_4^2 + q^2 + \frac{\gamma(\alpha)|eB|}{2} (q_3^2 + q_4^2) \exp(-\frac{q_\parallel^2}{2|eB|}) \right)).$$

(A.3)

Let us first evaluate the integral over $q_4$

$$\int_{-\infty}^{+\infty} dq_4 e^{-iq_4x_4} \exp\left(-sq_4^2 \left( 1 + \frac{\gamma(\alpha)|eB|}{2} e^{-\frac{q_\parallel^2}{2|eB|}} \right) \right).$$

(A.4)
For the new variable
\[ s' \equiv s \left(1 + \frac{\gamma(\alpha) |eB|}{2} e^{-\frac{s^2}{2\pi|eB|}}\right), \quad (A.5) \]
we get
\[ \int_{-\infty}^{+\infty} dq_4 e^{-iq_4 r - s'q_4^2} = \sqrt{\frac{\pi}{s'}} e^{-\frac{s^2}{4s'}}. \quad (A.6) \]

To integrate the variable \( q_3 \) component, let us go into the polar coordinate system. Here, the product \( \mathbf{q} \cdot \mathbf{x} \) is given by
\[ \mathbf{q} \cdot \mathbf{x} = qR \sin \theta \sin \theta' \cos (\varphi - \varphi') + q_3 R \cos \theta' \cos \theta, \quad (A.7) \]
with \( q \equiv |\mathbf{q}| \) and \( R \equiv |\mathbf{x}| \), \( \theta \) (\( \theta' \)) the angle between \( \mathbf{x} \) (\( \mathbf{q} \)) and the external magnetic field, which is assumed to be in the \( x_3 \)-direction. Now using \( q_3 = q \cos \theta' \) and \( q_\perp = q \sin \theta' \), \( (A.6) \) is given by
\[ \mathbf{q} \cdot \mathbf{x} = q_\perp R \sin \theta \cos (\varphi - \varphi') + q_3 R \cos \theta. \quad (A.8) \]

In these cylindric coordinates the photon propagator \( (A.3) \) is given by
\[ \tilde{\mathcal{D}}_{\mu\nu}(x) = \delta_{\mu\nu} \int_{0}^{\infty} ds \int \frac{dq_\perp dq_3 dq'}{(2\pi)^3} e^{-i(q_3 R \cos \theta + q_\perp R \sin \theta \cos (\varphi' - \varphi))} \]
\[ \times \exp \left(-s \left(q_3^2 + q_\perp^2 + \gamma(\alpha) |eB| \right) q_3^2 \exp \left(-\frac{q_3^2}{2|eB|}\right)\right) \sqrt{\frac{\pi}{s'}} e^{-\frac{s^2}{4s'}}, \quad (A.9) \]
where we have inserted the expression from \( (A.6) \). Now using the integral representation of the Bessel function \( J_0 \)
\[ J_0(z) = \frac{1}{2\pi} \int_{0}^{2\pi} d\varphi' e^{-iz \cos (\varphi' - \varphi)}, \quad (A.10) \]
and performing the integration over \( \varphi \) we get
\[ \tilde{\mathcal{D}}_{\mu\nu}(x) = \delta_{\mu\nu} \int_{0}^{\infty} ds \int \frac{dq_\perp dq_3}{(2\pi)^3} e^{-iq_3 R \cos \theta - s'q_3^2} J_0(q_\perp R \sin \theta) e^{-sq_3^2} \sqrt{\frac{\pi}{s'}} e^{-\frac{s^2}{4s'}}. \quad (A.11) \]
Performing now the integration over \( q_3 \) using
\[ \int_{-\infty}^{+\infty} dq_3 e^{-iq_3 R \cos \theta - s'q_3^2} = \sqrt{\frac{\pi}{s'}} e^{-\frac{R^2 \cos^2 \theta}{4s'}}. \quad (A.12) \]
The photon propagator \( (A.11) \) therefore reads
\[ \tilde{\mathcal{D}}_{\mu\nu}(x) = \delta_{\mu\nu} \int_{0}^{\infty} \frac{ds}{s'} \frac{dq_\perp}{8\pi^2} J_0(q_\perp R \sin \theta) e^{-sq_\perp^2} e^{-\frac{(s'^2 + R^2 \cos^2 \theta)}{4s'}}. \quad (A.13) \]
To perform the integration over \( q_\perp \) we proceed as follows. Using first the IR approximation \( q_\perp^2 \ll |eB| \) in the regime of LLL dominance, and expanding the factor \( e^{-\frac{q_\perp^2}{2|eB|}} \approx 1 - \frac{q_\perp^2}{2|eB|} + \frac{1}{2!} \frac{q_\perp^4}{4|eB|^2} \), the relation \( s'/s \) from \( (A.5) \) can be written as
\[ \frac{1}{s'} = \frac{2}{s\xi} \left(1 + \frac{\gamma q_\perp^2}{2\xi} + \left(\frac{\gamma^2}{4\xi^2} - \frac{\gamma}{8\xi |eB|}\right) q_\perp^4\right), \quad \text{with} \quad \xi \equiv (2 + \gamma |eB|). \quad (A.14) \]
For the first term on the second line of (A.16) we get therefore

\[ \bar{D}_{\mu\nu}(x) = \frac{\delta_{\mu\nu}}{4\pi^2} \int_0^\infty \frac{ds}{s} \int dq_1 q_1 J_0(q_1 R \sin \theta) e^{-s q_1^2} \left( 1 + \frac{\gamma q_1^2}{2\xi} + \frac{\gamma^2}{4\xi^2} - \frac{\gamma^2}{8\xi |eB|} q_1^4 \right) \]

\[ \times e^{-\left(\frac{x_1^2 + R^2 \cos^2 \theta}{2\xi}\right)} \left(1 + \frac{\gamma q_1^2}{2\xi} + \frac{\gamma^2}{4\xi^2} - \frac{\gamma^2}{8\xi |eB|} q_1^4 \right). \]  

(A.15)

Again using the IR approximation and expanding the exponent we get

\[ \bar{D}_{\mu\nu}(x) = \frac{\delta_{\mu\nu}}{4\pi^2} \int_0^\infty \frac{ds}{s} \int dq_1 q_1 J_0(q_1 R \sin \theta) e^{-s q_1^2} \]

\[ \times \left\{ 1 + \frac{\gamma q_1^2}{2\xi} \left(1 - \frac{b_1}{2s\xi}\right) + q_1^4 \left[ \frac{\gamma^2}{4\xi^2} \left(1 - \frac{b_1}{s\xi} + \frac{b_1^2}{8s^2\xi^2}\right) - \frac{\gamma}{8\xi |eB|} \left(1 - \frac{b_1}{2s\xi}\right) \right] \right\}, \]  

(A.16)

where

\[ b_1 \equiv x_1^2 + R^2 \cos^2 \theta. \]  

(A.17)

To perform the integration over \( q_1 \) we use [13]

\[ \int_0^\infty dz \ z^\mu e^{-\kappa z^2} J_\nu(z) = \Gamma \left(\frac{\mu + \nu + 1}{2}\right) \beta \kappa \frac{1}{\Gamma(\nu + 1)} e^{-\frac{\beta^2}{4\kappa}} M_{\frac{\nu + 1}{2}, \frac{\nu + 1}{2}} \left(\frac{\beta^2}{4\kappa}\right), \]

(A.18)

where \( M_{\frac{\nu + 1}{2}, \frac{\nu + 1}{2}}(y) \) is the Whittaker function defined by

\[ M_{\frac{\nu + 1}{2}, \frac{\nu + 1}{2}}(y) = y^{\frac{\nu + 1}{2}} e^{-\frac{y}{2}} \Phi \left(\frac{\nu - \mu + 1}{2}, \nu + 1; y\right), \]

(A.19)

where

\[ \Phi(\eta; \tau; y) \equiv 1 + \frac{\eta}{\tau} y + \frac{\eta(\eta + 1)}{\tau(\tau + 1)} y^2 + \cdots. \]  

(A.20)

For the first term on the second line of (A.16) we get therefore

\[ I_1(s) \equiv \int_0^\infty dq_1 J_0(q_1 R \sin \theta) e^{-s q_1^2} = \frac{1}{2s} e^{-\frac{R^2 \sin^2 \theta}{4s}}, \]

(A.21)

and for the second term we get

\[ I_2(s) \equiv \int_0^\infty dq_1^3 J_0(q_1 R \sin \theta) e^{-s q_1^2} = \frac{1}{2s^2} e^{-\frac{R^2 \sin^2 \theta}{4s}} \left(1 - \frac{R^2 \sin^2 \theta}{4s}\right), \]

(A.22)

whereas the third term yields

\[ I_3(s) \equiv \int_0^\infty dq_1^5 J_0(q_1 R \sin \theta) e^{-s q_1^2} = \frac{1}{s^3} e^{-\frac{R^2 \sin^2 \theta}{4s}} \left(1 - \frac{R^2 \sin^2 \theta}{2s} + \frac{R^4 \sin^4 \theta}{32s^2}\right). \]

(A.23)

Inserting (A.21), (A.22), and (A.23) in (A.16) we arrive first at

\[ \bar{D}_{\mu\nu}(x) = \frac{\delta_{\mu\nu}}{4\pi^2} \int_0^\infty \frac{ds}{s} \ e^{-\frac{b_1}{2s\xi}} \ \left\{ I_1(s) + \frac{\gamma}{2\xi} \left(1 - \frac{b_1}{2s\xi}\right) I_2(s) \right. \]

\[ \left. + \left[ \frac{\gamma^2}{4\xi^2} \left(1 - \frac{b_1}{s\xi} + \frac{b_1^2}{8s^2\xi^2}\right) - \frac{\gamma}{8\xi |eB|} \left(1 - \frac{b_1}{2s\xi}\right) \right] I_3(s) \right\}. \]

(A.24)
Finally, the integration over \( s \) can be evaluated using
\[
\int_0^\infty \frac{ds}{s^n} e^{-\frac{a}{s}} = \frac{\Gamma(n-1)}{a^{n-1}}.
\] (A.25)

Choosing the notation \( b_0 = R^2 \sin^2 \theta + \frac{2b_1}{\xi} \), we get for the first term in (A.24)
\[
\frac{\delta_{\mu\nu}}{8\pi^2 \xi} \int ds e^{-\frac{b_0}{s^2}} = \frac{\delta_{\mu\nu}}{2\pi^2 \xi b_0},
\] (A.26)
for the second term
\[
\frac{\delta_{\mu\nu} \gamma}{8\pi^2 \xi^2} \int ds e^{-\frac{b_0}{s^2}} \left(1 - \frac{b_1}{2s\xi}\right) I_2(s) = \frac{\delta_{\mu\nu} \gamma}{\pi^2} \left(-\frac{4b_1}{\xi^3 b_0^3} + \frac{12b_1 R^2 \sin^2 \theta}{\xi^3 b_0^4} + \frac{1}{\xi^2 b_0^2} - \frac{2R^2 \sin^2 \theta}{\xi^2 b_0^3}\right),
\] (A.27)
and the third term
\[
-\frac{\delta_{\mu\nu}}{4\pi^2} \int ds e^{-\frac{b_0}{s^2}} \left[\frac{\beta}{4\xi^2} \left(1 - \frac{b_1}{s\xi} + \frac{b_1^2}{8s^2 \xi^2}\right) - \frac{\gamma}{8\xi |eB|} \left(1 - \frac{b_1}{2s\xi}\right)\right] I_3(s) =
\]
\[
= \frac{8\delta_{\mu\nu} \gamma}{\pi^2 \xi^3 b_0^3} \left(1 - \frac{6R^2 \sin^2 \theta}{b_0} + \frac{6R^4 \sin^4 \theta}{b_0^2}\right)
\]
\[
-96\delta_{\mu\nu} \gamma^2 b_1 \left[1 - \frac{8}{b_0} \left(R^2 \sin^2 \theta + \frac{b_1}{4\xi}\right) + \frac{20}{b_0^2} \left(R^4 \sin^4 \theta + \frac{R^2 b_1 \sin^2 \theta}{\xi}\right) - \frac{30b_1 R^4 \sin^4 \theta}{\xi b_0^3}\right]
\]
\[
-\frac{4\delta_{\mu\nu} \gamma}{\pi^2 |eB| \xi^2 b_0^2} \left[1 - \frac{6}{b_0} \left(R^2 \sin^2 \theta + \frac{b_1}{\xi}\right) + \frac{6}{b_0^2} \left(R^4 \sin^4 \theta + \frac{8b_1 R^2 \sin^2 \theta}{\xi}\right) - \frac{60b_1 R^4 \sin^4 \theta}{\xi^2 b_0^3}\right].
\] (A.28)

Further, to find the LLL photon propagator in the regime \( |q_\parallel^2| \ll m^2_{d_{\text{dyn.}}} \ll |eB| \) from (III.16), we will first replace
\[
b_0 \to 4\beta a_1(R, \theta, x_4), \quad b_1 \to \frac{a_2(R, \theta, x_4)}{\beta \gamma}, \quad \text{and} \quad \xi \to (2\beta)^{-1},
\] (A.29)
where \( \beta \) and \( a_i, i = 1, 2 \) are defined in (III.18). Adding then the results from (A.26), (A.27) and (A.28) together we arrive at the propagator (III.16).

**APPENDIX B: THE LLL PHOTON PROPAGATOR IN \( m^2_{d_{\text{dyn.}}} \ll |q_\parallel^2| \ll |eB| \) REGIME**

In this section we will perform the integration over \( q \) in (III.23) to determine the full LLL photon propagator in \( m^2_{d_{\text{dyn.}}} \ll |q_\parallel^2| \ll |eB| \) regime (III.24). To start, let us give the integral (III.23) in the Euclidean space
\[
\bar{D}_{\mu\nu}(x) = \delta_{\mu\nu} \int \frac{d^4 q}{(2\pi)^4} e^{-i(q x + q \cdot x_0)} e^{-\frac{q_\parallel^2 + q^2 + 2a |eB|}{2}\frac{q_\parallel^2}{2\pi x_0^2}} ,
\] (B.1)
\[
\text{where we have introduced the Euclidean coordinates } x_0 = -ix_4 \text{ as well as } q_0 = -iq_4. \text{ Here, } q = (q_1, q_2, q_3) \text{ and } x = (x_1, x_2, x_3) \text{ and } q \cdot x = \sum_{i=1}^3 q_i x_i. \text{ Using the Schwinger parametrization}
\]
\[
\int_0^\infty ds e^{-as} = \frac{1}{a}.
\] (B.2)
the above expression (B.1) can be given by
\[
\tilde{\mathcal{D}}_{\mu\nu}(x) = \delta_{\mu\nu} \int_0^\infty ds \int \frac{d^3 q}{(2\pi)^4} e^{-i(q_4 x_4 + q \cdot x)} \exp \left( -s \left( q_4^2 + q^2 + \frac{2\alpha|eB|}{\pi} e^{-\frac{q_3^2}{2|eB|}} \right) \right). \tag{B.3}
\]
Performing the integration over \(q_4\)
\[
\int_{-\infty}^{+\infty} dq_4 e^{-sq_4^2 - iq_4 x_4} = \sqrt{\frac{\pi}{s}} e^{-\frac{s^2}{4s}}, \tag{B.4}
\]
we arrive at
\[
\tilde{\mathcal{D}}_{\mu\nu}(x) = \delta_{\mu\nu} \int_0^\infty ds \sqrt{\frac{\pi}{s}} e^{-\frac{s^2}{4s}} \int \frac{d^3 q}{(2\pi)^4} e^{-iqx} \exp \left( -s \left( q^2 + \frac{2\alpha|eB|}{\pi} e^{-\frac{q_3^2}{2|eB|}} \right) \right). \tag{B.5}
\]
To integrate the \(q\) component, we follow the same steps as in the previous section [see (A.7) and (A.8)] leading from (A.3) to (A.9). In the cylindric coordinates the photon propagator (B.5) is given by
\[
\tilde{\mathcal{D}}_{\mu\nu}(x) = \delta_{\mu\nu} \int_0^\infty ds \sqrt{\frac{\pi}{s}} e^{-\frac{s^2}{4s}} \int \frac{dq_\perp q_3 dq_3 d\varphi}{(2\pi)^4} e^{-i(q_\perp R \sin \theta \cos(\varphi - \varphi') + q_3 R \cos \theta)}
\times \exp \left( -s \left( q_\perp^2 + \frac{2\alpha|eB|}{\pi} e^{-\frac{q_3^2}{2|eB|}} \right) \right). \tag{B.6}
\]
Here \(\varphi' \in [0, 2\pi]\) and \(q_\perp \equiv |q_\perp| \in [0, \infty)\). Now using the integral representation of the Bessel function \(J_0\) from (A.10) and performing the integration over \(\varphi\) we get
\[
\tilde{\mathcal{D}}_{\mu\nu}(x) = \delta_{\mu\nu} \int_0^\infty ds \sqrt{\frac{\pi}{s}} e^{-\frac{s^2}{4s}} \int \frac{dq_\perp q_3 dq_3}{(2\pi)^3} e^{-iq_3 R \cos \theta} J_0(q_\perp R \sin \theta)
\times \exp \left( -s \left( q_\perp^2 + \frac{2\alpha|eB|}{\pi} e^{-\frac{q_3^2}{2|eB|}} \right) \right), \tag{B.7}
\]
where we have written \(q^2 = q_\perp^2 + q_3^2\). Performing now the integration over \(q_3\) in the same way as the integration over \(q_4\) [see (B.4)] we get first
\[
\int_{-\infty}^{+\infty} dq_3 e^{-sq_3^2 - iq_3 R \cos \theta} = \sqrt{\frac{\pi}{s}} e^{-\frac{R^2 \cos^2 \theta}{4s}}, \tag{B.8}
\]
and then
\[
\tilde{\mathcal{D}}_{\mu\nu}(x) = \delta_{\mu\nu} \int_0^\infty ds \sqrt{\frac{\pi}{s}} e^{-\frac{s^2}{4s}} \int \frac{dq_\perp q_3}{8\pi^2} J_0(q_\perp R \sin \theta) e^{-s \left( q_\perp^2 + \zeta^2 \exp(-\frac{q_3^2}{2|eB|}) \right)}, \tag{B.9}
\]
with \(\zeta^2 \equiv \frac{2\alpha|eB|}{\pi}\). To perform the integration over \(q_\perp\), we use the approximation, \(q_\perp^2 \ll |eB|\), which is valid in the regime of LLL dominance. After expanding the exponent
\[
e^{-s \left( q_\perp^2 + \zeta^2 \exp(-\frac{q_3^2}{2|eB|}) \right)} \approx e^{-s \zeta^2} e^{-s(1 - \frac{\alpha}{\pi}) q_\perp^2},
\]
the integration over \(q_\perp\) can be written as
\[
e^{-s \zeta^2} \int_0^\infty dq_\perp J_0(q_\perp R \sin \theta) e^{-s(1 - \frac{\alpha}{\pi}) q_\perp^2} = \frac{e^{-s \zeta^2}}{2s(1 - \frac{\alpha}{\pi})} \exp \left( -\frac{R^2 \sin^2 \theta}{4s(1 - \frac{\alpha}{\pi})} \right). \tag{B.10}
\]
To evaluate the $q_\perp$ integration, we have used \[13\]
\[
\int_0^\infty dz \, z^{\nu+1} J_\nu(\beta z) e^{-\gamma z^2} = \frac{\beta^\nu}{(2\gamma)^{\nu+1}} e^{-\beta^2/4\gamma}, \quad \text{Re}(\nu) > -1, \text{Re}(\alpha) > 0,
\]
by choosing $\gamma = s(1 - \frac{\alpha}{\pi})$, $\beta = R\sin \theta$, and $\nu = 0$. Plugging this result in (B.9) we arrive at
\[
\tilde{D}_{\mu\nu}(x) = -\frac{1}{16\pi^2 \left(1 - \frac{\alpha}{\pi}\right)} \int_0^\infty \frac{ds}{s^2} e^{-s\zeta^2 - \frac{1}{4\pi}(x^2 + R^2g^2(\theta))},
\]
where $g(\theta)$ is defined in (III.25). Defining a new variable $s' = \zeta^2 s$, the $s'$-integration can now be performed using
\[
\int_0^\infty \frac{ds'}{s'^{\nu+1}} e^{-s'^2 - \frac{1}{4\pi} s'} = \left(\frac{2}{\zeta}\right)\nu 2K_{\nu}(z).
\]
We arrive finally at the full LLL photon propagator in the regime $m_{\text{dyn.}}^2 \ll |\mathbf{q}_\parallel^2| \ll |eB|$ is then given by
\[
\tilde{D}_{\mu\nu}(R, \theta, x_4) = \frac{\delta_{\mu\nu}}{4\pi^2 \left(1 - \frac{\alpha}{\pi}\right)} \sqrt{x^2 + R^2g^2(\theta)} K_1 \left(\zeta \sqrt{x^2 + R^2g^2(\theta)}\right).
\]
For the notation $x_4 \to T$ we arrive therefore at our results from (III.24).
