Integrable Low Dimensional Theories Describing
High Dimensional Branes, Black Holes and
Cosmologies

Abstract

The reduction of higher dimensional supergravities to low dimensional dilaton gravity theories is outlined. Then a recently proposed new class of integrable theories of 0+1 and 1+1 dimensional dilaton gravity coupled to any number of scalar fields is described in more detail. These models are reducible to systems of independent Liouville equations whose solutions are not independent because they must satisfy the energy and momentum constraints. The constraints are solved, thus giving the explicit analytic solution of the theory in terms of arbitrary chiral fields. In particular, these integrable theories describe spherically symmetric black holes and branes of higher dimensional supergravity theories as well as superstring motivated cosmological models. Note that the reader is strongly recommended
to have a look into the transparencies of the lectures on which this text is based (http://www.phy.bg.ac.yu/mphys2/).

1 Introduction

The low dimensional field theories were usually considered as toy models for the ‘real’ four dimensional theory. Even the fact that some solutions of the higher dimensional theories may be consistently considered as low dimensional field theories or even one dimensional dynamical systems did not change the general attitude to low dimensional theories. The situation began to change with the development of string theory in which the connection between high and low dimensions is obvious and profound. Especially interesting are low dimensional dilaton gravity theories which are capable to describe some physically interesting phenomena in higher dimensions.

In fact, in the last decade 1+1 and 0+1 dimensional dilaton gravity coupled to scalar matter fields proved to be a reliable model for higher dimensional black holes and string inspired cosmologies. The connection between high and low dimensions has been demonstrated in different contexts of gravity and string theory - symmetry reduction, compactification, holographic principle, AdS/CFT correspondence, duality. For spherically symmetric configurations the description of static black holes, branes and of cosmological solutions even simplifies to 0+1 dimensional dilaton gravity - matter models, which in many interesting cases are explicitly analytically integrable (see e.g. [1] - [13] and references therein).

However, generally they are not integrable. For example, spherical black holes coupled to Abelian gauge fields are usually described by integrable 0+1 dimensional models, while the addition of the cosmological constant

\[ \ldots \]

\[ \ldots \]

\[ \ldots \]

\[ \ldots \]

\[ \ldots \]
term destroys integrability. In 1+1 dimension, pure dilaton gravity is integrable but the coupling to scalar matter fields usually destroys integrability. The one very well studied exception is the CGHS model. In 7 a more general integrable model of dilaton gravity coupled to matter, which incorporates as limiting cases the CGHS and other known integrable models was proposed. It reduces to two Liouville equations, whose solutions should satisfy two constraints. Because the general analytic solution of the constraints had been not found at that time, the model of Ref. 7 received little attention and was not studied in detail.

Recently, one of the authors has proposed a class of more general integrable dilaton gravity models in dimension 1+1, which are reducible to N Liouville equations (a brief summary is published in Ref. [15]). For these models the general analytic solution of the constraints has been found. It was demonstrated that the N-Liouville models are closely related to physically interesting solutions of higher dimensional supergravity theories describing the low energy limit of superstring theories. These 1+1 dimensional N-Liouville theories describe the solutions of higher dimensional theories in some approximation. On the other hand, their reduction to dimensions 1+0 (cosmological) and 0+1 (static black holes) give the exact solution of higher dimensional theories.

Static black holes and cosmological models are described by one dimensional solutions of the 1+1 dimensional theories. In the standard approach the deep connection between black holes and cosmologies is not transparent and is usually ignored (even the precise relation between the dimensional reductions used by ‘cosmologists’ and by ‘black holes investigators’ is not quite obvious). We thus start from the 1+1 dimensional formulation to get

\[ Some \ applications \ of \ this \ model \ were \ discussed \ in \ [14]. \ Note \ also \ that \ some \ recent \ cosmological \ models \ use \ potentials \ similar \ to \ those \ introduced \ in \ [7]. \ We \ will \ consider \ such \ applications \ in \ a \ separate \ paper. \]
a unified description of these two objects. A characteristic feature of the static solutions of the models derived from string theory is the existence of horizons with nontrivial scalar field distributions (what must be characteristic features of string cosmologies is as yet a much discussed problem).

It is well known that in the Einstein - Maxwell theories minimally coupled to scalar fields the spherical static horizons disappear if the scalar fields have a nontrivial space distribution (this is the so-called ‘no-hair theorem’). In Ref. [7], a local version of the no-hair theorem (we call it the ‘no horizon’ theorem) was formulated and proved. It states that, under certain conditions, there exists no static solution with a horizon in a class of 0+1 dimensional dilaton gravity theories coupled to scalar matter (the important requirement is that the scalar fields vary in space and are finite on the horizon). The theorem is local, and does not require any boundary conditions at infinity.

However, the ‘no horizon’ theorem is not true (as is known in several examples) for Einstein - Yang-Mills theories [17] as well as for solutions of higher dimensional supergravities, see e.g. [10]. In all these cases the static solutions of higher dimensional theories may be constructed by using the 1+1 or 0+1 dimensional dilaton gravity coupled to matter. In the integrable models we discuss here the solutions with horizons are completely identified and described in very simple terms. One may also consider the global properties of the solutions with or without horizons but we will not discuss this subject here.

In Section 2 we briefly demonstrate that spherically symmetric black holes and branes of higher dimensional supergravity theories, as well as superstring motivated cosmological models, may be described in terms of 0+1 and 1+1 dimensional dilaton gravity theories. In Sections 3, 4 a new class of integrable theories of 0+1 and 1+1 dimensional dilaton gravity coupled to any number of scalar fields is discussed. In Section 5 we outline
possible applications of the integrable models and some unsolved problems. In Appendix we present a derivation of some results and some useful formulas. Note that the models with nonlinear coupling of gauge fields to dilaton gravity were not considered in the literature in full generality and the construction of the effective potential for them is, to the best of our knowledge, a new result (this result was mentioned in [16] and in the report of one of the authors (A.T.F.) to the Third Sakharov Conference but its proof was not published).

2 High dimensional dilaton gravity

We first write the higher dimensional theories which, under dimensional reductions, produce special examples of integrable theories introduced in [7] and [15]. They all come from the low energy limit of the superstring theories, which is described by 10 dimensional supergravities. The bosonic part of the 10 dimensional supergravities of type II (corresponding to the type II superstrings) may be written as

$$L^{(10)} = L^{(10)}_{NS-NS} + L^{(10)}_{RR},$$

In this brief discussion it is sufficient to consider the first Lagrangian:

$$L^{(10)}_{NS-NS} = \sqrt{-g^{(10)}} e^{-2\phi_s} \left[ R^{(10)} + 4(\nabla \phi_s)^2 - \frac{1}{12} H_3^2 \right],$$

One may also start with the 11 dimensional supergravity, which is believed to be related to the so called ‘M - theory’, and reduce to 10 dimension by compactifying one dimension. Note also that here we are not attempting to consider compactifications of the most general supergravities. We only demonstrate the main features of the connection between low dimensional and high dimensional theories.

The second one gives similar 1+1 dimensional theories. Eventually, all bosonic and fermionic parts of the higher dimensional Lagrangians give in 1+1 dimension dilaton gravity coupled to scalar matter fields.
Here $\phi_s$ is the dilaton, related to the string coupling constant; $H_3 = dB_2$ is a 3-form; $g^{(10)}$ and $R^{(10)}$ are the 10 dimensional metric and scalar curvature respectively.

There are many ways to reduce high dimensional theories to low dimensions 1+1 and 0+1. We only mention here those that may lead to integrable theories. First, one may compactify the $d$ dimensional theory on a $p$ dimensional torus $T^p$ (or on several tori, including the circle $S^1$) using the Kaluza - Mandel - Fock - Klein (KMKF) mechanism\(^5\). This introduces $p$ Abelian gauge fields and at least $p$ scalar fields. Antisymmetric tensor fields ($n$-forms), which may be present in the high dimensional theory, will produce lower-rank forms and, eventually, other scalar fields. Thus we get a theory of gravity coupled to matter fields (scalars, Abelian gauge fields and, possibly, higher-rank forms) in a $d$ dimensional space, $d = D - p$. The next step is to reduce further its dimension by using some symmetry of the $d$ dimensional theory. The most typical one is the spherical symmetry (the axial symmetry leads to much more complex low dimensional theories and is not considered here). This step produces a 1+1 dimensional dilaton gravity theory coupled to scalar and gauge fields. The simplest example is the spherical reduction of the $d$ dimensional Einstein - Maxwell theory - the resulting 1+1 dimensional dilaton gravity is actually equivalent to a 0+1 dimensional theory.

The 1+1 dimensional dilaton gravity theories so derived may describe static black holes (static solutions), spherically symmetric evolution of the black holes (collapse of matter) and of the universe (expansion of the uni-

\(^5\)It is usually called the Kaluza - Klein (KK) mechanism but this is not justified historically. Actually, the Russian theorists George Mandel and Vladimir Fock have written their papers, in which they generalized the Kaluza theory, even somewhat earlier than Oscar Klein and published them in the same journal. We hope to redress this historical injustice in a separate publication
verse). In this sense, the flat space homogeneous cosmological models and static black holes may be regarded as the 1+0 and 0+1 dimensional reductions of the 1+1 dimensional theory and they can be connected in the frame of the 1+1 dimensional model.

Note that the final step in the chain of dimensional reductions in cosmology is usually somewhat different from that in black hole physics. Cosmological models are normally obtained by reducing the $d$ dimensional theory directly to dimension 1+0. Indeed, isotropy and homogeneity of the universe require a higher symmetry than the spherical one - the whole space should have constant curvature $k$, which may be equal to zero or $\pm 1$. These cosmologies can be selected from the set of the 1+0 dimensional solutions of the 1+1 dimensional theory by choosing a proper dimensional reduction of the metric and of the dilaton. We will not go into a detailed description of dimensional reductions, referring the reader to an instructive example in [3], [4], [10] and to reviews [11] - [13]. Instead we give a simplified typical chain of dimensional reductions leading to simple and important two dimensional and one dimensional dilaton gravity models.

Reducing to $d$ dimensions by different sorts of dimensional reduction (KMFK, compactification on tori, etc.) we obtain an effective Lagrangian $\mathcal{L}^{(d)}$. For our purposes it is sufficient to consider the following expression

$$\mathcal{L}^{(d)} = \sqrt{-g^{(d)}}e^{-2\phi_d}\left(R^{(d)} + 4(\nabla \phi_d)^2 - \frac{1}{2}(\nabla \psi)^2 - X_0 - X_1(\nabla \sigma)^2 - X_2F_2^2 \right).$$ (3)

Here $\phi_d$ is a new dilaton, $F_2$ is a 2-form (an Abelian gauge field); $X_a$ are functions of $\phi_d$ and $\psi$. Actually, the Lagrangian should depend on several $F_2$-fields, several $\psi$-fields, and may depend on several $\sigma$-fields as well as on higher - rank forms. However, after further reduction to two dimension only 2-forms and scalar fields will survive (in fact, the 2-forms can also be
excluded by writing an effective potential depending on electric or magnetic charges, see below).

We further reduce the $d$ dimensional theory to dimension 1+1 by spherical symmetry. Before and after doing so one may transform this Lagrangian by the Weyl conformal transformation, $g_{\mu\nu} \Rightarrow \tilde{g}_{\mu\nu} \equiv \Omega^2 g_{\mu\nu}$, where $\Omega$ depends on the dilaton. Expressing $R$ in terms of the new metric,

$$R = \Omega^2 \left[ \tilde{R} + 2(d-1)\nabla^2 \ln \Omega - (d-1)(d-2)(\nabla \ln \Omega)^2 \right],$$  

one can easily find the new expression for the Lagrangian. For $d > 2$ one can cancel the multiplier $e^{-2\phi_d}$ by choosing an appropriate function $\Omega(\phi_d)$ and thus write the Lagrangian in the so called Einstein frame (as distinct from the string frame expressions above). In dimension $d = 2$ it is impossible to remove the dilaton multiplier but, instead, one can remove the dilaton gradient term.

Now consider the spherically symmetric solutions of the $d$ dimensional theory (3). Usually, it is more convenient to remove the dilaton factor by a Weyl transformation and rewrite the action (3) in the Einstein frame, 

$$L_{(d)}^{E} = \sqrt{-g^{(d)}} \left[ R^{(d)} - \frac{1}{2} (\nabla \chi)^2 - \frac{1}{2} (\nabla \psi)^2 - X_0 e^{a_0 \chi} - X_1 e^{a_1 \chi} (\nabla \sigma)^2 - X_2 e^{a_2 \chi} F_2^2 \right],$$  

where $\phi_d \equiv \chi$ and $a_k$ are known constants depending on $d$. Then we parameterize the spherically symmetric metric by the general 1+1 dimensional metric $g_{ij}$ and the dilaton $\varphi$ ($\nu \equiv 1/n, \ n \equiv d-2$),

$$ds^2 = g_{ij} dx^i dx^j + \varphi^{2\nu} d\Omega^2_{(d-2)},$$  

introduce appropriate spherical symmetry conditions for the fields, which from now on will be functions of the variables $x_0$ and $x_1$ ($t$ and $r$), and integrate out the other (angular) variables from the $d$ dimensional action.
Applying, in addition, the Weyl transformation that removes the dilaton gradient term we thus obtain the effective 1+1 dimensional action

\[ \mathcal{L} = \sqrt{-g} \left[ \varphi R + n(n-1)\varphi^{-\nu} - X_0 e^{a_0 \chi} \varphi^{\nu} - X_2 e^{a_2 \chi} \varphi^{2-\nu} F^2 - \frac{1}{2} \varphi \left( (\nabla \chi)^2 + (\nabla \psi)^2 + 2X_1 e^{a_1 \chi} (\nabla \sigma)^2 \right) \right]. \tag{7} \]

Here \( \varphi \) is the 2-dilaton field that is often denoted by \( e^{-2\phi} \); the scalar fields \( \psi \) may have different origins – they may be former dilaton fields, KMFK scalar fields, reduced \( p \)-forms, etc. The functions \( X_k \) (we call them potentials) depend on the scalar fields \( \chi \) and \( \psi \), which from now on will be called scalar matter fields. Also the field \( \sigma \) may be regarded as a matter field but it plays a special role that will be discussed later. Notice that the potentials are positive and that \( n(n-1) \) is positive or zero\(^6\).

For dimensionally reduced supergravity theories one can often find a parameterization of the fields in which the potentials are exponentials of the matter fields while the kinetic (gradient) terms have the above simple structure. These 1+1 dimensional theories may have an integrable one dimensional sector describing static (0+1) or cosmological (1+0) solutions of the higher dimensional theories. The 1+1 dimensional theories obtained by dimensional reductions are usually not integrable but may often be approximated by explicitly analytically integrable 1+1 dimensional theories.

As it was mentioned above, the cosmological models are usually obtained from higher dimensional theories by a different dimensional reduction. To describe the homogeneous and isotropic universe one supposes that the metric may be written in the form

\[ ds^2 = -e^{2\nu(t)} dt^2 + e^{2\mu(t)} d\Omega^2_{(d-1)}(k), \tag{8} \]

\(^6\)This term is the curvature of the \( n \) dimensional sphere whose metric is given by the second term in (5). If, instead of the spherical symmetry, we used a pseudo-spherical one, the sign would be negative. If the \( n \) dimensional subspace is flat this term will be absent.
where $k = 0$ for the flat space and $k = \pm 1$ for the space of constant positive (negative) curvature.

Now, in cosmological models somewhat different reductions of the fields are of interest because the terms generated by the higher rank forms (characteristic of string theories) are believed to be of interest. However, after reducing to one dimension, also the higher rank forms give scalar fields either $\psi$ or $\sigma$ type. For example, in a typical reduction of the type IIA 10 dimensional supergravity to dimension 4 (compactification on an isotropic six dimensional torus $T^6$) and then to 1+0 dimensional dilaton gravity (see e.g. [18]), the 3-form produces in the one dimensional theory a $\sigma$ term while the 4-form generates an $X_0$-type potential. The cosmologies so obtained are in general not integrable.

## 3 1+1 dimensional dilaton gravity

Now let us consider a general 1+1 dimensional dilaton gravity coupled to Abelian gauge fields $F_{ij}^{(a)}$ and to scalar fields $\psi_n$. The general Lagrangian can be written as

$$
\mathcal{L} = \sqrt{-g} \left[ U(\varphi)R(g) + V(\varphi) + W(\varphi)(\nabla \varphi)^2 + 
X(\varphi, \psi, F_{(1)}^2, \ldots, F_{(4)}^2) + Y(\varphi, \psi) + \sum_n Z_n(\varphi, \psi)(\nabla \psi_n)^2 \right].
$$

(9)

Here $g_{ij}$ is a generic 1+1 dimensional metric with signature (-1,1) and $R$ is the Ricci curvature; $U(\varphi), V(\varphi), W(\varphi)$ are arbitrary functions of the dilaton field; $X, Y$ and $Z_n$ are arbitrary functions of the dilaton field and of $(N - 2)$ scalar fields $\psi_n (Z_n < 0)$; $X$ also depends on $A$ Abelian gauge fields $F_{(a)ij} \equiv F_{ij}^{(a)}, F_{(a)}^{(2)} \equiv g^{ij}F_{ij}^{(a)}F_{(a)}^{(2)}$. Notice that in dimensionally reduced theories (see (7)) both the scalar fields and the Abelian gauge fields are non-minimally coupled to the dilaton.

The equations of the theory (9) can be solved for arbitrary potentials
$U$, $V$, $W$ and $X$ if $\partial_\psi X \equiv 0$ (for the simplest explicit solution in case of $X$ linear in $F^2$ see e.g. [7] and references therein as well as the recent review [20]). Actually, only $V(\phi)$ and $X$ are really arbitrary functions. Moreover, for general potentials $X(\phi, \psi, F^2)$ one may solve the equations for $F^{(a)}_{ij}$ and then construct the effective action (see Appendix)

$$\mathcal{L}_{\text{eff}} = \sqrt{-g} \left[ \varphi R(g) + V_{\text{eff}}(\varphi, \psi) + \sum_n Z_n(\varphi, \psi) g^{ij} \partial_i \psi_n \partial_j \psi_n \right].$$

Here the effective potential $V_{\text{eff}}$ (below we omit the subscript) depends also on charges introduced by solving the equations for the Abelian fields. Note also that we use a Weyl transformation to exclude the kinetic term for the dilaton and also choose the simplest, linear parameterization for $U(\varphi)^7$.

If the effective potential does not depend on $\psi$, one can find the general solution for the matter vacuum when all $\psi$ are constant. In this case the equation of motion actually reduce to those of the pure dilaton gravity not coupled to scalar matter. Few 1+1 dimensional models are integrable. The best studied ones are the CGHS and JT models. They were essentially generalized in [7]. In all these models the $Z$-potentials are constant (so called minimal coupling). The only integrable class of models with non minimal coupling to scalar fields (with some special functions $Z_n(\phi)$) was proposed in [19].

Now we introduce a more general class of integrable 1+1 dimensional dilaton gravity models with minimal coupling to scalar fields. They are defined by the Lagrangian (10) with the following potentials:

$$Z_n = -1; \quad |f| V = \sum_{n=1}^N 2g_n e^{q_n}. \quad (11)$$

\footnote{If $U'(\varphi)$ has zeroes, this parameterization, as well as the more popular exponential one, $U = e^{\lambda \phi}$, is valid only between two consecutive zeroes.}
Here $f$ is the light cone metric, $ds^2 = -4f(u, v)\, du \, dv$, and
\[ q_n \equiv F + a_n \phi + \sum_{m=3}^{N} \psi_m a_{mn} = \sum_{m=1}^{N} \psi_m a_{mn}, \]  
(12)
where $\psi_1 + \psi_2 \equiv \ln |f| \equiv F (f \equiv \varepsilon e^F)$ and $\psi_1 - \psi_2 \equiv \phi$. Now, varying the Lagrangian (10) in $(N - 2)$ scalar fields, dilaton and in $g_{ij}$ and then passing to the light cone metric we find $N$ equations of motion for $N$ functions $\psi_n$,
\[ \epsilon_n \partial_u \partial_v \psi_n = \sum_{m=1}^{N} \varepsilon g_{nm} \varepsilon^{g_{nm}} a_{mn}; \quad \epsilon_1 = -1, \quad \epsilon_n = +1, \quad \text{if} \quad n \geq 2, \]  
(13)
and two constraints,
\[ C_i \equiv f \partial_i (\partial_i \phi / f) + \sum_{n=3}^{N} (\partial^2 \psi_n)^2 = 0, \quad i = (u, v). \]  
(14)

For arbitrary coefficients $a_{mn}$ the equation of motion are not integrable. However, if the $N$-component vectors $v_n \equiv (a_{mn})$ are pseudo-orthogonal, the equations of motion can be reduced to $N$ Liouville equations for $q_n$,
\[ \partial_u \partial_v q_n - \tilde{g}_n \varepsilon^{q_n} = 0, \]  
(15)
where $\tilde{g}_n = \varepsilon \lambda_n g_n$, $\lambda_n = \sum a_{mn^2}$, and $\varepsilon \equiv |f| / f$ (note that the equations for $q_n$ depend on $\epsilon_n$ only implicitly, through the normalization factor $\lambda_n$).

The most important fact is that the constraints can be explicitly solved. By writing the solutions of the Liouville equations in the form suggested by the conformal field theory,
\[ e^{-q_n / 2} = a_n(u) b_n(v) + \bar{a}_n(u) \bar{b}_n(v), \]  
(16)
where $\bar{a}$ and $\bar{b}$ can be expressed in terms of $a$ and $b$, i.e.
\[ e^{-q_n / 2} = a_n(u) b_n(v) \left[ 1 - \frac{1}{2} \bar{g}_n \int \frac{du}{a_n^2(u)} \int \frac{du}{b_n^2(v)} \right], \]  
(17)
we may rewrite the constraints in the form
\[ C_u = \sum_{n=1}^{N} a_n''(u) [\lambda_n a_n(u)]^{-1}, \quad C_v = \sum_{n=1}^{N} b_n''(v) [\lambda_n b_n(v)]^{-1}. \]  
(18)
Using the fact that the norms $\lambda_n$ satisfy the constraint $\sum_{n=1}^{N} \lambda_n^{-1} = 0$ (this is a consequence of the pseudo-orthogonality conditions) we can solve these constraints. The solution has the following form:

$$\frac{a_n'(u)}{a_n(u)} = \alpha_n(u) - \frac{\sum_{n=2}^{N} \lambda_n^{-1}(\alpha_n' + \alpha_n^2)}{2\sum_{n=2}^{N} \lambda_n^{-1}\alpha_n},$$

where $\alpha_1 = 0$ and the other $\alpha_n$ are arbitrary functions of $u$. The ratios $b_n'(v)/b_n(v)$ are expressed by the same equation in terms of functions $\beta_n(v)$.

By integrating the first order differential equations for $a_n(u)$ and $b_n(v)$ we thus find the general solution of the $N$-Liouville dilaton gravity in terms of $(2N - 2)$ arbitrary chiral fields $\alpha_n(u)$ and $\beta_n(v)$. With proper conditions of convergence one may use this solution also for $N = \infty$.

4 Integrable 0+1 dimensional dilaton gravity coupled to matter

The dimensional reduction from 1+1 to 0+1 dimensions in the light cone coordinates $(u, v)$ is very simple. If we suppose that $\varphi = \varphi(\tau)$, $\psi_n = \psi_n(\tau)$ where $\tau = a(u) + b(v)$, we find from the 1+1 dimensional equations of motion that

$$f(u, v) = \mp h(\tau) a'(u) b'(v)$$

and thus

$$ds^2 = -4f(u, v) du dv = \pm 4h(\tau) d\alpha d\beta.$$ (21)

Defining two dimensional space and time coordinates $r = a \pm b$ and $t = a \mp b$ we find that

$$ds^2 = h(\tau)(dt^2 - dr^2), \quad \text{where} \quad \tau = r \text{ or } \tau = t,$$ (22)

and thus the reduced solution may be the static or the cosmological one\textsuperscript{8}.

\textsuperscript{8}Of course, in 2d theories this distinction is not very important. However, when we know the higher dimensional theory from which our 2d dilaton gravity originated,
However, this is not the most general way for obtaining 0+1 or 1+0 dimensional theories from higher dimensional ones. Not all possible reductions can be derived by this simple dimensional reduction of the 1+1 dimensional gravity. For example, to derive the cosmological solutions corresponding to the reductions \( \mathcal{N} \) one should use a more complex dimensional reduction of the 1+1 dimensional dilaton gravity, which will be discussed elsewhere.

It is not difficult to show that the 0+1 dimensional equations are described by the Lagrangian \( (\ln |h| = F, \varepsilon = \pm) \) \[7\]:

\[
\mathcal{L} = -\frac{1}{l} \left( \dot{\phi} \dot{F} + \sum_n Z_n(\varphi, \psi) \dot{\psi}_n^2 \right) + l \varepsilon e^F V(\varphi, \psi), \quad \text{(23)}
\]

where \( l(t) \) is the Lagrange multiplier (related to the general metric \( g_{ij} \)).

Now, the two-dimensionally integrable \( N \)-Liouville theories presented above are also integrable in 0+1 dimension. Moreover, as we can solve the Cauchy problem in dimension 1+1 we can study the evolution of the initial configurations to stable static solutions, e.g. black holes, which are special solutions of the 0+1 dimensional reduction. However, the reduced theories can be explicitly solved for much more general potentials \( Z_n \) and \( V \).

Suppose that for \((N-2)\) scalar fields \( \psi_n \ (n = 3, \ldots, N) \) the ratios of the \( Z \)-potentials are constant so that we can write \( Z_n = -\gamma_n/\phi'(\varphi) \) (in eq. \[7\] these are the fields \( \chi \) and \( \psi \) and \( \phi = \ln \varphi \)). Suppose that all the potentials \( Z_n \) and \( V \) be independent of the scalar fields \( \psi_{N+k} \) with \( k = 1, \ldots, K \) (in eq. \[7\] this is the field \( \sigma \)). Then, we first remove the factor \( \phi'(\varphi) \) by defining the new Lagrange multiplier \( \bar{l} = l(\tau)\phi'(\varphi) \) and absorb the factors \( \gamma_n > 0 \) in the corresponding scalar fields. In this way we may introduce the new dynamical variable \( \phi \) instead of \( \varphi \). Now we can solve the equations for the we can reconstruct the higher dimensional metric and thus find the higher dimensional interpretation of our solutions. In the remaining part of these lectures we do not introduce \( r \) and \( t \), take in \[20\] the upper sign and usually call all one dimensional solutions static.
σ-fields and construct the effective Lagrangian\(^9\). We thus may arrive at the effective Lagrangian

\[
L_{\text{eff}} = -\frac{1}{l} \left[ \bar{l} \dot{\phi} - \sum_{n=3}^{N} \dot{\psi}_n^2 \right] + l \left[ \varepsilon e^{F} V_{\text{eff}}(\phi, \psi) + V_{\sigma}(\phi, \psi) \right].
\] (24)

Here \(V_{\text{eff}} = V/\phi'(\varphi)\) and \(V_{\sigma} = \sum_{k} C_{k}^{2}/Z_{N+k} \phi'(\varphi)\) where \(\varphi\) must be expressed in terms of \(\phi\). If the original potentials in eq. (23) are such that \((Z_{N+k} \phi'(\varphi))^{-1}\) and \(V/\phi'\) can be expressed in terms of sums of exponentials of linear combinations of the fields \(\phi\) and \(\psi\), then there is a chance that the 0+1 dimensional theory can be reduced to Liouville or Toda equations (the Toda case is possible only if \(V_{\sigma} \neq 0\)).

The pure Liouville case was introduced in [15] and is described by the Lagrangian (in notations of eq. (12))

\[
L = \frac{1}{l} \left( -\dot{\psi}_1^2 + \sum_{n=2}^{N} \dot{\psi}_n^2 \right) + l \sum_{n=1}^{N} 2g_n e^{g_n}.\] (25)

If the \(a_{mn}\) satisfy our pseudo orthogonality conditions, the equations of motion are reduced to \(N\) independent one dimensional Liouville equations whose solutions have to satisfy the energy constraint. The solutions are expressed in terms of elementary exponentials (for simplicity, we write the solution in the gauge \(l(\tau) \equiv 1\) but all the results are actually gauge invariant):

\[
e^{-q_n} = \frac{|\tilde{g}_n|}{2\mu_n^2} \left[ e^{\mu_n(\tau-\tau_n)} + e^{-\mu_n(\tau-\tau_n)} + 2\varepsilon_n \right],\] (26)

where \(\varepsilon_n = -|\tilde{g}_n|/\tilde{g}_n\), \(\mu_n\) and \(\tau_n\) are the integration constants (\(\mu_n^2\) and \(\tau_n\) are real). The constraint can be shown to be \(\sum_{n} \mu_n^2/\lambda_n = 0\), and its solution is trivial. The space of the solutions is thus defined by the \((2N-2)\) dimensional moduli space (one of the \(\tau_n\) may be fixed). One can show that

---

\(^9\)It is better to do this in the Hamiltonian formalism but space limitations force us to omit details of our derivations.
the solutions have at most 2 horizons\textsuperscript{10} and the space of the solutions with horizons has dimension \((N - 1)\). There exist integrable models having solutions with horizons and no singularities but their relation to the high dimensional world is at the moment not clear.

Note that the solution \((26)\) is written in a rather unusual coordinate system. One may write a more standard representation remembering that the dilaton \(\phi\) is related to the coordinate \(r\) (see \((6)\)). This may be useful for a geometric analysis of some simple solutions (e.g. Schwarzschild or Reissner-Nordstrøm) but in general the standard representation is very inconvenient for analyzing the solutions of the \(N\)-Liouville theory.

5 Discussion and outlook

The explicitly analytically integrable models presented here may be of interest for different applications. The most obvious one is to use them to construct first approximations to generally non integrable theories describing black holes and cosmologies. Realistic theories of these objects are usually not integrable (even in dimension 0+1). Having explicit general solutions of the zeroth approximation in terms of elementary functions it is not difficult to construct different sorts of (classical) perturbation theories.

For example, spherically symmetric static black holes non minimally coupled to scalar fields are described by the integrable 0+1 dimensional \(N\)-Liouville model. However, the corresponding 1+1 dimensional theory is not integrable because the scalar coupling potentials \(Z_n\) are not constant (see eq.\((7)\)). To obtain approximate analytic solutions of the 1+1 dimensional

\textsuperscript{10}To prove this one should analyze the behavior of \(q_n\) for \(|\tau| \to \infty\) and for \(|\tau - \tau_n| \to 0\) (if \(\varepsilon_n < 0\)). The horizons appear when \(F \to -\infty\) while \(\phi\) and \(\psi_n\) for \(n \geq 2\) tend to finite limits. This is possible for \(|\tau| \to \infty\) if and only if \(\mu_n = \mu\). When \(F \to F_0\) and \(\phi \to \infty\) we have the flat space limit, e.g. exterior of the black hole. The singularities in general appear for \(|\tau - \tau_n| \to 0\) if \(\varepsilon_n < 0\).
theory one may try to approximate $Z_n$ by properly chosen constants.

It may be useful to combine this approach with the recently proposed analytic perturbation theory allowing to find solutions near horizons for the most general non integrable 0+1 dilaton gravity theories [21]. The detailed description of the $N$-Liouville (and of the Toda type) theories, as well as applications to black holes and cosmology, will be given elsewhere. The Toda type theories were earlier introduced by direct reductions of higher dimensional theories to cosmological models (see e.g. [13], [9] and references therein).

6 Appendix

6.1 Reduction of the Curvature

We usually consider the block diagonal dimensional reduction

$$ds^2 = g_{ij} dx^i dx^j + h_{mn} dx^m dx^n,$$

where the metric depends only on the coordinates of the first subspace, $x^i$.

The Ricci curvature scalar for this metric then can be written as

$$R = R[g] + R[h] - \frac{2}{\sqrt{h}} \nabla^m \nabla_m \sqrt{h} + \frac{1}{4} g^{ij} \partial_i h^{mn} \partial_j h_{mn} + \frac{1}{4} g^{ij} (h^{mn} \partial_i h_{mn}) (h^{pq} \partial_i h_{pq}).$$

Using this expression, partial integrations, and the Weyl transformations one may easily derive the reductions presented in the main text. If the
second subspace is a $d - 2$ dimensional sphere of radius $e^\mu$ then

$$R[h] = e^{-2\mu}k(d - 2)(d - 3),$$

where $k = 1$ for the sphere ($k = -1$ for the pseudo sphere and $k = 0$ for the flat space; these objects appear in the cosmological reductions). To help the reader in keeping trace of relations between dimensions $d$, $1+1$, $1+0$ and $0+1$ we also write here a simple expression for the curvature in dimension 1+1. We take the diagonal metric

$$ds^2 = -e^{2\nu}dt^2 + e^{2\mu}dr^2. \quad (29)$$

The Ricci scalar $R$ for this metric is

$$R = 2e^{-2\nu}(\ddot{\mu} + \dot{\mu}^2 - \dot{\mu}\dot{\nu}) - 2e^{-2\mu}(\nu'' + \nu'^2 - \nu'\mu'). \quad (30)$$

For this metric, one may also need the expression for $\nabla^2 \phi$, where $\phi$ is an arbitrary scalar field:

$$\nabla^2 \equiv \nabla^n\nabla_m \phi = -e^{-2\nu}(\ddot{\phi} + (\dot{\mu} - \dot{\nu})\dot{\phi}) + e^{-2\mu}(\phi'' + (\nu' - \mu')\phi'). \quad (31)$$

All these expressions simplify in the $(u, v)$ coordinates that can be obtained by taking $\nu = \mu$ and introducing the light cone coordinates, which is always possible for the 1+1 dimensional metric (having the Minkowski signature). Denoting $e^{2\nu} = e^{2\mu} = f$ we have

$$ds^2 = f(dr^2 - dt^2), \quad R = \frac{1}{f}(\partial_t^2 - \partial_r^2) \ln |f| \quad (32)$$

At this point one may introduce the $(u, v)$ metric which drastically simplifies the equations of motion and all computations. One may, for example, write $t = u + v$ and $r = u - v$ and the metric will have the standard form

$$ds^2 = -4f(u, v)du \, dv. \quad (33)$$
However, had we chosen \( r = u + v \) and \( t = u - v \), what may look more natural in considering static solutions, the sign in (33) would change. Moreover, there is a residual symmetry in the \((u,v)\) coordinates, namely, \( u \to a(u), \ v \to b(v) \). Under this transformation (33) transforms as

\[
ds^2 = -4 f(a(u), b(v)) a'(u) b'(v) \, du \, dv = -4 f(a, b) \, da \, db. \tag{34}
\]

Thus the metric in the coordinates \((a,b)\) is the same as in the \((u,v)\) coordinates. Also the curvature and equations of motion remain invariant.

This freedom is useful for many reasons. For example, suppose we have found a solution of the equation of motion, for which the metric \( f \) and the dilaton \( \varphi \) depend only on \( uv \). Then, choosing \( a = \ln u, \ b = \ln v \), we may go to coordinates \((a,b)\) in which the metric function and the dilaton depend on \( a + b \) (this may be interpreted as \( r \) or as \( t \))\(^{11}\). More generally, the solutions of integrable models may usually be written in terms of massless free fields \( \chi_n \) which are solutions of the D’Alembert equation and thus may be written as a sum of left moving fields \( a_n(u) \) and right moving ones \( b_n(v) \), \( \chi_n = a_n + b_n \). If all \( \chi_n \) are equal, i.e. \( \chi_n = a(u) + b(v) \), the theory reduces to one dimension\(^{12}\). In the same way one may dimensionally reduce the general, non integrable models. We describe the simplest approach using the light cone coordinates. The more standard approach uses coordinates \( r \) and \( t \). It is more cumbersome but may be of use for interpreting the low dimensional solutions as solutions of higher dimensional theories.

\(^{11}\)This means that the 1+1 dimensional metric is effectively one dimensional. If it originated from the higher dimensional spherically symmetric metric (3), this also should be effectively one dimensional. This, however, does not mean that the whole theory reduces to one dimension, because the scalar matter fields may still depend on two variables (see e.g. [19]).

\(^{12}\)It is a good exercise to find a free field representation for the \( N \)-Liouville theory and to reduce it to one dimension by using this idea.
6.2 Reduction of the Equations

First, let us write the equations of motion in the light cone $(u, v)$ coordinates (their derivation from the Lagrangian (10) is a good exercise for the reader).

To simplify the formulas we keep only one scalar field:

$$\mathcal{L} = \sqrt{-g} \left( \varphi R + V(\varphi, \psi) + Z(\nabla\psi)^2 \right).$$  \hfill (35)

In the $(u, v)$ coordinates they are

\begin{align*}
\partial_u \partial_v \varphi + f V(\varphi, \psi) & = 0, \quad \hfill (36) \\
\partial_v (Z \partial_u \psi) + \partial_u (Z \partial_v \psi) + f V(\varphi, \psi) & = Z\varphi \partial_u \psi \partial_v \psi, \quad \hfill (37) \\
f \partial_i \left( \frac{\partial_i \varphi}{f} \right) & = Z (\partial_i \psi)^2, \quad i = u, v, \quad \hfill (38) \\
\partial_u \partial_v \ln |f| + f V(\varphi, \psi) & = Z\varphi \partial_u \psi \partial_v \psi, \quad \hfill (39)
\end{align*}

where $V_\varphi = \partial_\varphi V, V_\psi = \partial_\psi V, Z_\varphi = \partial_\varphi Z, Z_\psi = \partial_\psi Z$. Equations (36) – (39) are not independent. Actually, (39) follows from equations (36) – (38).

Alternatively, if (36), (38), (39) are satisfied, (37) is satisfied.

The most important equations are the constraint equations (37). A general formulation of the dimensional reduction is suggested by the following simple observation. Consider the solutions with constant scalar field $\psi \equiv \psi_0$ (the ‘vacuum’ solution). This solution exists if and only if $V_\psi(\varphi, \psi_0) = 0$, see eq. (37). Then the constraints can be solved because their right-hand sides are identically zero. It is not difficult to prove (this is a simple exercise) that there exist chiral fields $a(u)$ and $b(v)$ such that

$$\varphi(u, v) \equiv \varphi(\tau), \quad \text{and} \quad f(u, v) \equiv \varphi'(\tau) a'(u) b'(v),$$

where the primes denote derivatives with respect to the corresponding argument. Using this result it is easy to prove that eq. (36) has the integral

$$\varphi' + N(\varphi) = M,$$
where $N(\varphi)$ is defined by the equation $N'(\varphi) = V(\varphi, \psi_0)$ and $M$ is the integral of motion which for the black hole solutions is proportional to the mass of the black hole. The horizon, defined as a zero of the metric $h(\tau) = M - N(\varphi)$, exists because the equation $M = N(\varphi)$ has at least one solution in some interval of values of $M$. We see that the equations of motion in the considered case are actually dimensionally reduced. Their solutions can be interpreted as black holes (including the Schwarzschild, the Reissner Nordstrøm and other known black hole solutions in any dimension) or as cosmological models (including the Friedmann - Robertson - Walker cosmology and its generalizations).

The more general static solutions with horizons and more general cosmologies are not described by the scalar vacuum solutions. They are not the general solutions of the 1+1 dimensional equations and are derived as solutions of differently chosen one dimensional sectors of the 1+1 dimensional theory. Here we introduce the simplest dimensional reduction. As we work in the light cone coordinates, the interpretation and comparison to the standard considerations requires reintroducing the $(t, r)$ coordinates as it can be done simply and generally.

Taking into account the lesson of the scalar vacuum solutions, we introduce the dimensional reduction by supposing that the scalar fields and the dilaton depend on one free field $\tau$ (after dimensional reduction it is interpreted as the space or the time coordinate):

$$\varphi = \varphi(\tau), \quad \psi = \psi(\tau), \quad \tau = a(u) + b(v). \quad (40)$$

Then, it follows from eq. (36) that the metric should have the form

$$f(u, v) = \varepsilon h(a + b) a'(u) b'(v), \quad (41)$$

where $\varepsilon$ is introduced in order to have the same type of metric for the 0+1
and 1+0 cases:

$$\textstyle ds^2 = h(\tau)(dr^2 - dt^2) \quad (42)$$

Usually one defines the $r$ and $t$ coordinates in terms of $u$ and $v$. More generally, we may define them in terms of $a(u)$ and $b(v)$. Defining

$$\tau \equiv a + b, \quad \bar{\tau} \equiv a - b, \quad (43)$$

we have from eq. (41)

$$\textstyle ds^2 - 4f(u,v) du \, dv = -4\varepsilon h \, da \, db = -\varepsilon h (d\tau^2 - d\bar{\tau}^2), \quad (44)$$

and thus both reduced metrics may be written as by choosing $\tau = r$, $\varepsilon = -1$ or $\tau = t$ and $\varepsilon = +1$.

The reduced equation of motion for the dilaton and for the scalar field,

$$\partial_\tau^2 \varphi + \varepsilon h V = 0, \quad 2\partial_\tau (Z\partial_\tau \psi) + \varepsilon h V_\psi = Z_\psi (\partial_\tau \psi)^2, $$

depend on $\varepsilon$ while the constraints are the same for both reductions and give just one reduced constraint,

$$\textstyle \partial_\tau^2 \varphi - \partial_\tau \varphi \partial_\tau \ln |h| = Z(\partial_\tau \psi)^2, $$

that is equivalent (in the standard terminology) to the energy constraint.

Thus we have the rule for the reduction of the equations of motion: using the equations in the light cone gauge, derive the equations for $\varphi(\tau), \psi(\tau), \varepsilon h(\tau)$ and then take $\tau = r$ and $\varepsilon = -1$ or $\tau = t$ and $\varepsilon = +1$.

One may avoid writing the 1+1 dimensional equations of motion by directly reducing the Lagrangian (35). To do this one may start from the 1+1 dimensional Lagrangian in the general diagonal metric,

$$\textstyle ds^2 = -h_0 dt^2 + h_1 dr^2, $$
and derive the Lagrangian for the 0+1 reduction \((h_0(r), h_1(r))\) and the 1+0 reduction \((h_0(t), h_1(t))\) separately. However there is a simpler and more direct way which allows to write the correct equations without calculations.

First, take the gauge fixed Lagrangian in the \((u, v)\) metric,

\[
\mathcal{L} = \varphi \partial_u \partial_v F + fV - Z \partial_u \psi \partial_v \psi \tag{45}
\]

where \(F = \ln |f|\). Due to the residual covariance with respect to the transformation \(u \to a(u), v \to b(v)\), we may equivalently write

\[
\mathcal{L} = \varphi \partial_a \partial_b F + \varepsilon hV - Z \partial_a \psi \partial_b \psi. \tag{46}
\]

Then, substituting in this Lagrangian \((40)\) and \((41)\) we obtain

\[
\mathcal{L} = \varphi \dot{F} - Z \dot{\psi}^2 + \varepsilon hV,
\]

where the dot denotes \(\tau\)-differentiation. This Lagrangian is equivalent to

\[
\mathcal{L} = -\dot{\varphi} \dot{F} - Z \dot{\psi}^2 + \varepsilon hV, \tag{47}
\]

and it gives the correct reduced equations of motion.

Let us restore the lost constraint (the gauge fixed Lagrangian \((46)\) does not give the constraints). To do this we recall that the constraint is just \(\mathcal{H} = 0\), where \(\mathcal{H}\) is the Hamiltonian correspondent to the Lagrangian. It is evident that

\[
\mathcal{H} = -\dot{\varphi} \dot{F} - Z \dot{\psi} - \varepsilon hV. \tag{48}
\]

Now it is easy to guess that the correct Lagrangian giving the equations of motion and the constraint \(\mathcal{H} = 0\) is simply

\[
\mathcal{L} = -\frac{1}{l(\tau)} \left( \phi \dot{F} + Z \dot{\psi}^2 \right) + l(\tau) \varepsilon hV. \tag{49}
\]

In order to obtain from here the 0+1 theory we simply take \(\tau = r\) and \(\varepsilon = -1\). The 1+0 theory can be written taking \(\tau = t\) and \(\varepsilon = +1\).
Finally, let us write an example of cosmological reduction directly from a higher dimensional theory. We take the $d$ dimensional metric (8), suppose that the scalar functions depend on one variable $t$ (the gauge field is reduced differently, see e.g. [11]. Then using eq. (28) with the one dimensional metric $g$ and the $d-1$ dimensional metric $h$ we can find for example the reduced action for the $d$ dimensional Lagrangian (5). We write here only the reduced curvature part (the derivation of the other terms is obvious):

$$S = \int d^d x \sqrt{-g} \sqrt{h} R^{(d)} = \int dt \epsilon^{\nu} \epsilon^{\mu(d-1)} [k(d-1)(d-2)e^{-2\mu} -$$

$$-(d-1)(d-2)e^{-2\nu} \dot{\mu}^2]. \quad (50)$$

6.3 Nonlinear coupling of gauge fields

Suppose that, in place of the standard Abelian gauge field term, $X(\varphi, \psi)F^2$, the Lagrangian contains a more general coupling of the gauge field $F_{ij} = \partial_i A_j - \partial_j A_i$ to dilaton and scalar fields, $\mathcal{F}(\varphi, \psi; F^2)$ (for example, one may consider the Born - Infeld type terms). The equation of motion for the gauge field is

$$\partial_i \left( \sqrt{-g} \frac{\partial \mathcal{F}}{\partial (\partial_i A_j)} \right) = 0, \quad (51)$$

where

$$\frac{\partial \mathcal{F}}{\partial (\partial_i A_j)} = 4F^{ij} \frac{\partial \mathcal{F}}{\partial F^2},$$

reduces in 1+1 dimension to the conservation law

$$\sqrt{-g} F^{ij} \frac{\partial \mathcal{F}}{\partial F^2} = \epsilon^{ij} \lambda Q \quad (52)$$

where $\epsilon^{ij} = -\epsilon^{ji}$, $\epsilon^{01} = 1$, $\lambda$ is a constant to be defined later and $Q$ is a conserved charge. Using this equation we can express $F_{ij}$ in terms of $F^2$:

$$F^{ij} = \frac{\epsilon^{ij} \lambda Q}{\sqrt{-g}} \left( \frac{\partial \mathcal{F}}{\partial F^2} \right)^{-1}. \quad (53)$$
From this it is easy to obtain the equation for $F^2$ (recall that $2g = \varepsilon^{ij}\varepsilon^{lk}g_{il}g_{jk}$):

$$F^2 = -2\lambda^2Q^2\left(\frac{\partial F}{\partial F^2}\right)^{-2}. \quad (54)$$

This allows (in principle) to write $F^2$ (and $F_{ij}$) in terms of $\varphi$, $\psi$, $Q$. Let us denote the solution as $\bar{F}^2 \equiv \bar{F}^2(\varphi, \psi; Q)$ (or simply $\bar{F}^2$). Now we can write $F^{ij}$ in terms of $\bar{F}^2(\varphi, \psi; Q)$. Equation (54) gives

$$\frac{\partial \bar{F}}{\partial F^2} \equiv \frac{\partial F}{\partial F^2}_{|F^2=\bar{F}^2} = \epsilon\sqrt{2\lambda Q}/\sqrt{-\bar{F}^2}, \quad (55)$$

where $\bar{F} \equiv F(\varphi, \psi; \bar{F}^2)$, $\epsilon = \text{sign}[\partial F/\partial F^2]$ and $\sqrt{-\bar{F}^2} > 0^{13}$. Then from equations (54) and (55) we get

$$F^{ij} = \varepsilon^{ij}\lambda Q\sqrt{-g} \left(\frac{\partial \bar{F}}{\partial F^2}\right)^{-1} = \varepsilon^{ij} \epsilon \sqrt{\bar{F}^2/2g}. \quad (56)$$

Now we can exclude the gauge fields from the equations of motion. In order to do this, let us find an effective potential $F_{eff}$ depending only on $\varphi$, $\psi$ and $\bar{F}^2(\varphi, \psi; Q)$. To simplify the computation we go to the $(u,v)$ coordinates in which

$$F^{uv} = \frac{1}{4f^2}F_{uv}, \quad F^2 = -\frac{1}{2f^2}F^2_{uv}. \quad (57)$$

Note that in order to obtain the complete equations of motion including the constraints we should use the $(u,v)$ coordinates after computing the variations of $\mathcal{L}$ in the diagonal metric coefficients $g_{ii}$. Only then we may set $g_{ii} = 0$ and $g_{uv} = g_{vu} = -2f$. Note also that the other variations (in $\varphi, \psi$) can be derived from the $(u,v)$ reduced (gauge fixed) Lagrangian

$$\mathcal{L} = \varphi\partial_u\partial_v\ln|f| + fV(\varphi, \psi) - Z\partial_u\psi\partial_v\psi + f\mathcal{F}(\varphi, \psi; F^2). \quad (58)$$

In order to find the effective potential $F_{eff}$ we derive the expression for the variation $\delta(f\mathcal{F})$ with respect to $f$. We need not calculate the variation with respect to $g_{ii}$ because

$$\frac{\delta F^2}{\delta g^{ii}} = 2g^{jk}F_{ij}F_{ik} \equiv 0 \quad \text{when} \quad g_{jj} = 0$$

---

For small values of $F^2$ we have usually $\epsilon < 0$. 

25
(this also means that the constraints are insensitive to the $F^2(\varphi, \psi, F^2)$ term when we use the $(u, v)$ coordinates).

Now we have (we don’t set yet $F^2 = \bar{F}^2$)

$$
\delta_f(fF) = F \delta f + f \frac{\partial F}{\partial F^2} \cdot \frac{\partial F^2}{\partial f} \cdot \delta f = (F - 2F^2 \frac{\partial F}{\partial F^2}) \delta f \quad (59)
$$

because

$$
\frac{\partial F^2}{\partial f} = \frac{\partial}{\partial f} \left( -\frac{1}{4F^2} F^2_{uv} \right) = -\frac{2}{F} F^2.
$$

Using in (59) the relations (55) and (56) we obtain

$$
\delta_f(fF)|_{F^2 = \bar{F}^2} = \delta f \left[ F(\varphi, \psi, \bar{F}^2) + 2\sqrt{2} \lambda Q \epsilon \sqrt{\bar{F}^2} \right]. \quad (60)
$$

The right hand side of (60) produces the effective potential we are looking for,

$$
F_{eff}(\varphi, \psi, \bar{F}^2) \equiv F(\varphi, \psi, \bar{F}^2) + 2\sqrt{2} \lambda Q \epsilon \sqrt{\bar{F}^2}. \quad (61)
$$

To prove this it is sufficient to differentiate the derivatives of $F_{eff}$ with respect to $\bar{F}^2$, to $\varphi$ and to $\psi$. From

$$
\frac{\partial F_{eff}}{\partial F^2} = \frac{\partial F}{\partial F^2} - \epsilon \sqrt{2} \lambda Q / \sqrt{\bar{F}^2}
$$

we see that the main equation defining $\bar{F}^2$ will be reproduced if we set $\partial F_{eff}/\partial \bar{F}^2 = 0$ (as we should do, because now we consider $\bar{F}^2$ as a new variable). If we now express $F_{eff}$ in terms of $\varphi, \psi, Q$, i.e.

$$
F_{eff}(\varphi, \psi; \bar{F}^2(\varphi, \psi, Q)) \equiv F_{eff}(\varphi, \psi; Q),
$$

we find that

$$
\frac{dF_{eff}}{d\varphi} = \frac{\partial F}{\partial \varphi} + \left( \frac{\partial F}{\partial F^2} - \epsilon \sqrt{2} \lambda Q / \sqrt{\bar{F}^2} \right) \frac{\partial \bar{F}^2}{\partial \varphi} = \frac{\partial F}{\partial \varphi}
$$

due to (59). Analogously, $dF_{eff}/d\psi = \partial F/\partial \psi$. This means that the $\varphi, \psi, f$ equations of motion for the effective Lagrangian $L_{eff}$ (in which $F$ is replaced by $F_{eff}$) coincide with the $\varphi, \psi, f$ equations of motion for the Lagrangian $L$ and give the correct expression for $\bar{F}^2$ and $\bar{F}_{ij}$. (Note that we did not use the equations of motion for $\varphi, \psi, f$ in our derivation of $F_{eff}$.)
Thus we can include $F_{eff}$ into the effective potential, i.e. define

$$V_{eff}(\varphi, \psi; Q) = V(\varphi, \psi) + F_{eff}(\varphi, \psi; Q) \quad (62)$$

and forget about the fields $F_{ij}, A_i$ that can be derived from eq. (56) if needed.

It is not difficult to understand that $F$ may depend on any number of fields $\psi$ and any number of abelian gauge fields $F_n^2$. Thus in general the effective potential will be given by

$$F_{eff} = F(\varphi, \psi; \bar{F}_n^2) + 2\sqrt{2} \sum_n Q_n \epsilon_n \sqrt{-F_n^2}$$

where the quantities $\bar{F}_n^2$ are solutions of the equations

$$F_n^2 = -2\lambda^2 Q_n^2 \left( \frac{\partial F}{\partial F_n^2} \right)^2 \quad \text{and} \quad \epsilon_n \equiv \text{sign} \left[ \frac{\partial F}{\partial F_n^2} \right].$$

Now consider a simple example. Let us take the Born - Infeld expression for $F$

$$F = \alpha \sqrt{\beta^2 + F^2}$$

where $\alpha$ and $\beta$ are functions of $\varphi, \psi \ (\beta > 0)$. Applying our formulae we get the following effective potential:

$$F_{eff} = \frac{\beta}{|\alpha|} \sqrt{\alpha^2 + \bar{Q}^2} \quad \text{where} \quad \bar{Q}^2 \equiv 8\lambda^2 Q^2.$$ 

Now, if $\alpha$ is a constant, $\alpha = \alpha_0$, and $\beta = g^2 \exp(2\mu \varphi + 2\nu \psi)$ we obtain an exponential effective potential:

$$F_{eff} = ge^{\mu \varphi + \nu \psi} \frac{\alpha}{|\alpha|} \sqrt{\alpha_0^2 + Q^2}.$$ 

Consider now the case $F^2 << \beta^2$. Then

$$F = \alpha \beta \left(1 \pm \frac{F^2}{2\beta^2} + \ldots\right) = \alpha \beta \pm \frac{F^2}{2\beta/\alpha} + \ldots$$

Using our formula we have the well known result

$$F_{eff} = \alpha \beta \pm 2\lambda^2 Q^2 \left( \frac{2\beta}{\alpha} \right) + \ldots$$
