Behaviors

ABSTRACT

Recently, extremely low frequency electromagnetic fields (ELF-EMF) have received considerable attentions for their potential pathogenicity. In the present study, we explored the effects of ELF-EMF on behaviors of adult male rats. Sixty adult male rats were randomly divided into two groups, the sham exposure group and the 50 Hz/100 μT ELF-EMF exposure group. During the 24 weeks exposure, body weight, as well as food and water intake were recorded. Results showed that food and water intake and the body weight of the rats were not affected by the exposure. After 24 weeks exposure, open field test and elevated plus maze were conducted to evaluate the anxiety-like behavior, the tail suspension test and forced swim test were conducted to evaluate depression-like behavior and Morris water maze and fear conditioning tests were used to evaluate the cognitive and memory ability. Exposure to ELF-EMF did not induce any anxiety-like or depression-like behaviors compared with the sham exposure. Moreover, the cognitive and memory ability was not impaired by the ELF-EMF exposure. Furthermore, ELF-EMF exposure did not affect the morphology and histology of the brain. In conclusion, 24 weeks exposure to 50 Hz/100 μT ELF-EMF had no effect on the behaviors of the adult male rats.

1. Introduction

There are rising concerns over the biological effects of extremely low frequency electromagnetic field (ELF-EMF). In 1979, Wertheimer and Leeper first reported that there might be a possible relationship between the electromagnetic fields and childhood cancer (Wertheimer and Leeper, 1979). Recent studies have evaluated the effects of the ELF-EMF on cancer (Chen et al., 2013; Repacholi, 2012), reproductive system (Al-Akhras et al., 2006; Huusonen et al., 2001; Vallejo and Hidalgo, 2012), endocrine system (Crasson et al., 2001; Karasek and Woldanska-Ookonska, 2004; Taherianfard et al., 2013) as well as neurodegenerative diseases (Garcia et al., 2008; Reale et al., 2014; Sobel et al., 1995). However, due to different exposure conditions, such as the duration and the intensity of exposure, there remains considerable controversy surrounding the safety of ELF-EMF.

It is widely recognized that when the electric appliances are turned on or the power lines are transmitting, there will be a physical field called electromagnetic field (EMF) (I.A.R.C., 2002). The EMF can be classified into three categories based on the frequency. One of them is ELF-EMF, which has a frequency ranging from 1 Hz to 300 Hz (Feychting et al., 2005). ELF-EMF exposure is very common in daily life because most appliances possess a frequency of 50 Hz or 60 Hz (Karasek and Woldanska-Ookonska, 2004).

As mentioned above, the ELF-EMF is a physical field induced by the exchange current (I.A.R.C., 2002). In daily life, the electric appliances are the main sources of the ELF-EMF, and human body is a good conductor of the ELF-EMF. Thus, when people get close to the ELF-EMF, there will be an oscillating charge induced on the surface of the exposed body and current will be produced inside the body (I.C.N.I.R.P., 2010).

It is believed that the current is not harmful to human body because it can neither break bonds nor heat body tissues (Feychting et al., 2005). In 2007, The World Health Organization...
(WHO) declared that ELF-EMF had no adverse effect on human health after a ten years follow-up study (W.H.O., 2007). This was supported by other studies. For instance, Chen et al. suggested that ELF-EMF exposure had no association with the susceptibility to female breast cancer (Chen et al., 2010).

However, some studies reported that ELF-EMF may affect the nerve cells. It was reported by Mustafa et al. that exposure to ELF-EMF can induce oxidative stress and apoptosis (Emre et al., 2011). Besides, Komaki et al. found that ELF-EMF exposure may change the synaptic plasticity in hippocampus (Komaki et al., 2014). Furthermore, it was shown that exposure to ELF-EMF significantly reduced the cerebral ischaemia-induced motor hyperactivity in gerbils (Raus et al., 2012). Animal behavior is regulated by the central nervous system. The hippocampus and amygdala have been linked to anxiety-like behavior (Meyer-Lindenberg, 2010), and the hippocampus has also been found to play an important role in learning and memory (Bird and Burgess, 2008). However, the effects of ELF-EMF on animal behavior remain inconclusive.

Our previous work has shown that short term ELF-EMF exposure did not affect learning and memory as assessed by Morris water maze (Zhang et al., 2015b). In the present study, we employed adult male rats to investigate whether the exposure to ELF-EMF (50 Hz, 100 µT) would influence behavior, including anxiety-like behavior, depression-like behavior, spatial learning, fear learning and memory using more comprehensive measurements.

2. Methods and materials

2.1. Ethics statement

The study protocol was approved by the committee on the Ethics of Animal Experiments of the Animal Research Committee of Tongji Medical College. All experimental protocols complied with U.K. Animals (Scientific Procedures) Act, 1986 and associated guidelines, the European Communities Council Directive of 24 November 1986 (86/609/EEC) or the National Institutes of Health guide for the care and use of Laboratory animals (NIH Publications No. 8023, revised 1978) and the ARRIVE guidelines. All efforts were made to minimize suffering. The operations that could cause pain and distress were performed in another room without other animals present. Anaesthetization of rats was performed under the effect of repeated testing performed every 3 months: Salmonella spp., Bordetella bronchiseptica, Mycoplasma spp., Corynebacterium kutscheri, Tyzzer’s organism, Pasteurella pneumotropica, Klebsiella pneumonia, Staphylococcus aureus, Pseudomonas aeruginosa, Han-tavirus (HV), Sendai virus (SV), Pneumonia virus of mice (PVM), Reovirus type III (Reo-3), Rat parvovirus KRV, Rat parvovirus H-1, Rat coronavirus. During the exposure, all these rats were visited daily and showed good health status without any evidence of sickness and none of the rats died. Food and water intake was recorded every 2 weeks and the weight of the rat was determined every 4 weeks.

2.3. Exposure device

The exposure device (200 cm × 70 cm × 200 cm, L × W × H) was constructed with ABS plastics (Yite electric, Wuhan, China) and utilized the bronze wires (Yite electric, Wuhan, China) to produce the electric magnetic field referred to the exposure device of American Electric Power Research Institute (EPRI). A TG2D transformer (Mushidq, Shanghai, China) was placed and the voltage was adjusted to maintain the intensity of the field to be 100 µT. Inside the device, we settled a four floors plastic shelf with a size of 140 cm × 70 cm × 200 cm (L × W × H). Before use, the distribution of the electromagnetic field was determined with Narda efa-300 (Narda, Pfullingen, Germany) and the distribution map was drawn.

2.4. Behavior assessment

After 24 weeks exposure, behavior assessment was carried out. Totally, 6 tests were carried out: open field test (OFT) and elevated plus maze (EPM) were used to evaluate anxiety-like behavior, tail suspension test (TST) and forced swim test (FST) were used to examine the effects on depression-like behavior, Morris water maze (MWM) and fear conditioning test were carried out to observe the influence on learning and memory. As described above, we divided the both groups into 3 subsets and subjected to different behavioral tests, separately. For each behavior, ten ELF-EMF exposure rats and ten sham exposure rats were tested. All the tests were conducted in the morning from 9:00 to 15:00. In order to minimize the impact caused by the time of testing, the animals of the two groups were tested alternately. All these experiments were recorded with a camera connected to the recording and analysis system. The system and the experimental instruments were located in an independent room to avoid the interference of artificial factors. For all behavioral tests, rats were brought to the testing room more than half an hour before the test.

2.5. Open field test (OFT)

In the OFT, a square apparatus 1000 mm in length and 450 mm in height was used. The internal area of the apparatus was divided into nine equal parts, which included one central area and a peripheral area divided into eight outer areas. The camera was positioned on the right top of the apparatus. The detailed procedure of OFT has been reported before (Prut and Belzung, 2003; Qi et al., 2015; Seibenhener and Wooten, 2015). In brief, after half hour adaption to the testing room, rats were put into the central area of the apparatus and the system started to record at the same time. For
each rat, we recorded for 20 min. The total distance traveled, accumulative distance in peripheral area, as well as the time spent and distance traveled in the central area were recorded and analyzed by two observers who were blind to the group assignment of animals.

2.6. Elevated plus maze (EPM)

EPM was utilized to evaluate the effects on anxiety-like behavior (Walf and Frye, 2007). The instrument consisted of two closed arms and two open arms raised 50 cm above the floor. In brief, for each test, the rat was placed in the center of the cross facing an open arm, and was allowed to explore the maze for 6 min. Percentage of time spent in open arms, percentage of entries in open arms, and total entries as well as entries in open arms were analyzed. Effects on anxiety-like behavior were assessed based on the entries in open arms as well as time spent in the open arms, while the total number of entries indicated locomotor activity. All the data were analyzed by two observers who were blind to the group assignment of animals.

2.7. Tail suspension test (TST)

TST was carried out as previously reported (O’Reilly et al., 2006). The total duration of immobility was measured in seconds. Rats were suspended with the tail on a horizontal beam 50 cm above the floor. Each rat was considered immobile only when rat hung passively and completely motionless. A 6 min test period was used and the duration of immobility was recorded during the last 4 min of the test session. All the data were analyzed by two observers who were blind to the group assignment of animals.

2.8. Forced swim test (FST)

The FST procedure was performed with a glass cylinder (200 mm in diameter and 600 mm in height) filled with warm water (25 ± 1 °C) as previously described (Lucki et al., 2001; Slattery and Cryan, 2012). For each rat, the water depth was adjusted to make sure the rat swam. A total of 6 min of testing was carried out and the immobility time was measured in seconds only when rat made movements to take its head out of the water. After each test, the water in glass cylinder was replaced with the fresh water at the same temperature. Animals were placed in warmed holding cages for at least 30 min before being returned to their home cages. Only the time recorded during the last 4 min was analyzed, by two observers who were blind to the group assignment of animals.

2.9. Morris water maze (MWM)

The MWM was used to assess the effects on spatial learning and memory. The detailed procedure has been reported before (Vorhees and Williams, 2006). In brief, a circular tank (180 cm in diameter and 60 cm in height) filled with opaque water was used and the temperature was maintained at 25 °C. The tank was divided into four quadrants with an invisible platform. During the 6 days training, there were four trials every day. For each trial, rat was put into the water in one of the quadrants facing the tank wall. Rat started in a different, randomized position for each trial. Each rat was allowed to swim until it found the platform and remained on the platform for 10 s or 60 s had expired. If 60 s expired, they were hand-guided to it. The probe test was performed on the seventh day. Before the test, the platform was removed. Then, the rats were placed into the water. The time spent in the target quadrant and the times crossing the platform area were recorded and analyzed to evaluate the animal’s spatial memory. All the data were analyzed by two observers who were blind to the group assignment of animals.

2.10. Fear conditioning test

Rats were subjected to fear conditioning test as previously described (Zhang et al., 2015a) at 24 h after the completion of Morris water maze. On the first day, animals were brought to the testing room and subjected to the chamber which was made of black walls. Three tone-foot shock pairings (tone: 2000 Hz, 85 dB, 30 s; foot shock: 1 mA, 2 s) were carried out. The chamber was cleaned with 75% ethanol and dried between tests. On the second day, the animals were placed back to the same chamber for 6 min without the tone and shock. The percentage of freezing behavior time was recorded. Two hours later, we changed the test chamber which was different in condition and smell from the first chamber. The tone stimulus was turned on for 3 min. The video was recorded and the freezing time was analyzed by two observers who were blinded to the group assignment of animals.

2.11. Histological analysis

After exposure, all the animals were sacrificed and the brains were isolated. All the brains were weighed immediately after removal (n = 30). Subsequently, the brains were fixed with 4% neutral formalin, followed by dehydrated and prepared to paraffin sections. Total 12 coronal sections in the same range for each rat were collected, from a rostrocaudal direction from 1.80 to 4.8 mm posterior to the bregma (Paxinos and Watson, 1997). Samples were treated with the HE staining kit (Jiancheng Bioengineering Institute, Nanjing, China) according to the manufacturer’s protocol. For neuron staining, the samples were incubated with NeuN-antibody (Abcam, Cambridge, UK), and 0.3% hydrogen peroxide solution was used to block the endogenous peroxidase, following application of the appropriate biotinylated secondary antibody. Finally, sections were developed with the DAB substrates. Photos were taken using the Olympus inverted microscope (Olympus, Tokyo, Japan) and analyzed by the pathologist who was blind to the animal assignment. The dorsal lateral geniculate nucleus (DLG) was used as the landmark of the hippocampus and the striatum was used as the landmark of the amygdala.

The neuron density was carried out on the sections stained with NeuN-antibody (Atkins et al., 2013). Neurons were counted in adjacent sections for each rat using a magnification of 200× for hippocampus (CA3 region) and 40× for amygdala. Neurons were identified as NeuN positive cells, distinguished by size and their morphology. The reference size of the photos was calculated by Image pro plus 6 program using the reference scale. The neuron density was calculated based on the mean total population numbers and reference size.

2.12. Statistical analysis

All results are presented as mean ± standard error of mean (S.E.M.), the data recorded in blocks across time were statistically analyzed by repeated measures analysis of variance (ANOVA) and other data were statistically analyzed using one-way ANOVA. It was considered to be statistically significant, only when p value < 0.05.

3. Results

3.1. Effects of ELF-EMF on the general condition

Before the exposure, we constructed an exposure device and examined the distribution of the EMF, which turned out to be
uniform (Fig. S1). The adult male rats were randomly divided into two groups, the EMF group that was exposed to 50 Hz, 100 μT EMF, and the control group exposed with a sham exposure device. All the animals were exposed for 24 weeks. The general condition was recorded and the results showed that the weight of the rats was not influenced by the ELF-EMF exposure (Fig. S2A). As shown in Fig. S2B and C, food intake and water intake were not affected by the ELF-EMF exposure.

3.2. Effects of ELF-EMF on the performance in the OFT and EPM

The anxiety-like behavior can be evaluated by the OFT and EPM. In the OFT, the accumulative distance traveled in total, accumulative distance in the peripheral area, distance traveled in the central area as well as the time spent in the central area were recorded. Results showed that the accumulative distance traveled was not influenced by the exposure to ELF-EMF (Fig. 1A), suggesting that ELF-EMF had no effects on the locomotor activity. Similarly, the accumulative distance in the periphery of the EMF group was not significantly different from that of the control group (Fig. 1B). Meanwhile, the accumulative distance traveled and the time spent in the central area were not affected by the ELF-EMF exposure (Fig. 1C and D).

Moreover, EPM was also carried out to explore the effects of ELF-EMF on the anxiety-like behavior. First, we assessed the locomotor activity of the animals by analyzing the total entries into the arms. Results showed that ELF-EMF had no effect on the total entries into the arms (Fig. 2A). Then, we analyzed the time spent, the percentage of the total time in the open arms, the entries and the percentage of the entries into the open arms. As shown in Fig. 2B–E, ELF-EMF exposure did not influence the animal's time spent and entries in the open arms.

Taken together, ELF-EMF had no effect on the animal's anxiety-like behavior.

3.3. Effects of ELF-EMF on the performance in the TST and FST

The depression-like behavior can be assessed by the TST and FST, which are the classical ethological models of depression-like behavior assessments. In both tests, depression motion was represented by the immobility time. In TST, the immobility time was not influenced by the ELF-EMF exposure (Fig. 3A). Similarly, in FST, ELF-EMF exposure showed no effects on the immobility time compared to the control group (Fig. 3B).

3.4. Effects of ELF-EMF on learning and memory

Learning is the basis of memory. If there is no learning, there can be no memory later (Johansen et al., 2011). We employed the Morris water maze (MWM) to measure the spatial learning and memory. The MWM was first reported in 1984 by Morris (Morris, 1984), and was used to evaluate the spatial learning and memory ability. As shown in Fig. 4A and B, during the training stage, the escape latency and the distance traveled decreased from the 1st day to the 6th day in control group, and the trends of the ELF-EMF exposure group were similar. However, the ELF-EMF exposure showed no interaction with the testing time, and had no effects on the performances at each single time point. On the 7th day, the
platform was removed, and the locomotor activity of the animals was assessed. The accumulative distance traveled in the tank of the ELF-EMF exposure group was not significantly different from that of the control group (Fig. 4C). Moreover, the time to cross the platform area was measured, and the results revealed that rats from control group remembered the platform area and swam across the area around 6 times in average, which was similar to the ELF-EMF exposed rats (Fig. 4D). In addition, the effects of ELF-EMF on the spatial memory were further detected by the residence time spent in the target quadrant, which showed no significant difference between the two groups (Fig. 4E). Together, these data showed that ELF-EMF exposure had no effects on the spatial learning and memory.

Moreover, the rats were subjected to the fear conditioning system to determine the fear learning and memory ability. Results showed that animals from the control group and ELF-EMF exposure group both had a good learning ability (Fig. 5A). Although the observations were significantly different among the different testing time, the ELF-EMF exposure showed no interaction with the testing time, and had no effects on the performance at each single time point. Moreover, results from the cued test showed that the animals from both groups had a good memory of fear, and there was no difference in the context related and tone related freezing behavior between the two groups (Fig. 5B and C).

Taken together, exposure to ELF-EMF had no effect on animal’s cognitive and memory ability, especially for the space and fear.

3.5. ELF-EMF exposure did not affect the morphology and histology of the brain

For further evidence, we evaluated the effects of ELF-EMF exposure on the animal’s brain. No animals became ill or died prior to the experimental endpoint. As shown in Fig. 6A and B, the brain

![Fig. 2. Effects of ELF-EMF exposure in elevated plus maze. (A) Time spent in the open arms; (B) percentage of the time spent in the open arms; (C) total entries into the arms; (D) entries in open arms; (E) percentage of the entries into the open arms. All data were presented as mean ± S.E.M.](image-url)
weight and the ratio of the brain weight to the body weight was not influenced by the exposure to the ELF-EMF. Moreover, ELF-EMF exposure did not change the morphology of the brain, no difference was observed in the structure of the hippocampus and amygdala as shown in the HE staining (Fig. 6C and D). Importantly, results from the immunohistochemistry with NeuN antibody showed that the neuron density was not affected by the exposure to ELF-EMF (Fig. 6E and F).

4. Discussion

In this study, we carried out several classical behavior tests to evaluate the effects of ELF-EMF on different kinds of behaviors. Results showed that exposure to 100 μT ELF-EMF for 6 months had no effect on animal’s behavior, including the general behavior, locomotor activity, anxiety-like behavior, depression-like behavior, spatial learning and memory, as well as fear learning and memory.

Exposure to chronic psychological stress promotes brain-to-immune and immune-to-brain communication that directly influences neurobiology and behavior, which may lead to mental health disturbances, such as anxiety and depressive disorders (Wohleb et al., 2014). Recent studies are mainly focused on the biological effects of ELF-EMF, but little is known about the effects of ELF-EMF on various behaviors.

The effects of ELF-EMF on anxiety-like behavior remain incompletely understood. In 1997, an epidemiological investigation suggested that ELF-EMF exposure for over ten years might enhance the occurrence of anxiety disorders in human (Zyss et al., 1997), which was further supported by Boscolo et al. in a 13 years follow-up study (Boscolo et al., 2006). In rodents, similar effects were observed. It was reported that chronic (4 h/day, 25 days) 2 mT ELF-EMF had anxiogenic effects on rats (Liu et al., 2008). Besides, studies carried out by Del et al. showed that exposure to 80 μT magnetic field for 2 h altered behavioral patterns in OFT (Del Seppia et al., 2003). However, it was reported recently that mice exposed to ELF-EMF (1 mT) for 14 days can still maintain normal anxiety-like behavior (Alsaed et al., 2014). In addition, Szemerszky et al. showed that 4–6 weeks exposure to 500 μT ELF-EMF had no effect on anxiety-like behavior (Szemerszky et al., 2010). Similarly, Cosquer et al. reported that exposure to EMF for 45 min did not alter rat’s anxiety responses assessed by the elevated plus maze (Cosquer et al., 2005). In our present study, we carried out OFT and EPM to evaluate the effects of 100 μT ELF-EMF on anxiety-like behavior. Results from both tests revealed that 6 months exposure to ELF-EMF did not influence anxiety level of the animals. The conflicting results between our study and others may due to the differences in experimental conditions, such as the exposure intensity, exposure duration. Nevertheless, it should be noted that our ELF-EMF source was very stable and uniform, which makes our results more persuasive.

Some publications pointed out that chronic stress generated by ELF-EMF may induce a depressive state. In 1993, study by Poole et al. compared subjects on properties proximity to power line with subjects further away. They reported a relative risk of 2.8 for depressive symptoms and headache (95% confidence interval (CI), 1.6–5.1) (Poole et al., 1993). Later, in 2009, Szemerszky et al. exposed rats to ELF-EMF (50 Hz, 0.5 mT) for 4–6 weeks, and the results suggested that ELF-EMF exposure enhanced the depressive-like behavior (Szemerszky et al., 2010). Other studies showed that ELF-EMF did not affect depression-like behavior. For example, study designed by Savitz et al. suggested that ELF-EMF exposure did not increase the risk of depression in electrical workers (Savitz et al., 1994). Analogously, in the present study, we used the TST and FST to observe the depressive state of the rats. Results showed no significant difference between the two groups. The different results among studies may be due to various intensity of ELF-EMF investigated. Moreover, in the current study, we used adult rats as the subjects which excluded the confounding factors (e.g. age, sex and illness).

Morris water maze was first reported in 1984 (Morris, 1984), and subsequently became one of the most frequently used laboratory tools in behavioral neuroscience. In previous study, our group had shown that 100 μT ELF-EMF exposure for 12 weeks did not affect the spatial learning in MWM (Zhang et al., 2015b). In the present study, similar results were observed even though the exposure time was prolonged to 24 weeks. Studies carried out by Li et al. suggested that 100 μT ELF-MF exposure did not interfere with the improvement in learning and memory capabilities (Li et al., 2014). And this effect could also be observed in head-only exposure to EMF for 45 min (Dubreuil et al., 2003). In contrast, Cui et al. found that ELF-MF exposure (1 mT, 50 Hz) for 12 weeks induced marked oxidative stress in the hippocampus and striatum and impaired hippocampus dependent spatial learning and striatum-dependent habit learning (Cui et al., 2012), which was further confirmed by Maaroufi et al. They reported that rats exposed to EMF for 21 consecutive days were impaired in the object exploration task, and the monoamine content of hippocampus was altered (Maaroufi et al., 2014).

Fig. 3. Influence of ELF-EMF exposure in tail suspension test and forced swim test. (A) The immobility time of the TST. (B) The immobility time of the FST. After 24 weeks exposure, the animals were subjected to the TST and FST. The immobility time in the last 4 min was recorded. All data were presented as mean ± S.E.M.
Fig. 4. Effects of ELF-EMF exposure on the behavior in the Morris water maze. (A) The escape latency in learning phase; (B) the accumulative distance traveled before animals arrived the platform in learning phase; (C) accumulative distance traveled in probe trial; (D) times crossing the platform area in probe trial; (E) time spent in the target quadrant in probe trial. The escape latency was draw from the data recorded during the learning phase from day 1 to day 6. On the day 7, the probe trial was carried out with the platform removed and the accumulative distance traveled, times crossing the platform area and time spent in the target quadrant was measured. All data were presented as mean ± S.E.M.

Fig. 5. Effects of ELF-EMF exposure in fear conditioning test. (A) Fear acquisition during the stimulation with 3 tone-foot shock pairings (tone: 2000 Hz, 85 dB, 30 s; foot shock: 1 mA, 2 s); (B) the time percentage of the context related freezing behavior; (C) the time percentage of the tone related freezing behavior. Freezing time of the control and ELF-EMF exposure group were monitored and captured by mounted camera and analyzed by the software program. All data were presented as mean ± S.E.M.
Besides, we are the first to employ the fear conditioning test to evaluate the effects of ELF-EMF exposure on fear learning and memory. Our results suggested that both the hippocampus dependent and independent learning and memory were not impaired by ELF-EMF exposure, since context related and tone related fear conditioning reflect hippocampus dependent and hippocampus independent learning and memory (Kim and Fanselow, 1992).

In our study, exposure to 100 μT ELF-EMF had no effect on animal’s behavior, which was different from some of the previous studies. However, the exposure intensity used was much higher in previous studies, even more than 1 mT, which is much higher than that humans encounter in daily life. For human, the recommended limitation of public exposure is 100 μT (I.C.N.I.R.P., 1998, 2010). This may be one of the reasons for the different results. In the present study, we used the recommended intensity to expose the animals.

However, additional questions remain to be answered. For example, the effects of ELF-EMF exposure on the female’s behavior remain unknown. Compared to the males, the females have different sex hormone levels (Becker et al., 2005), like higher estradiol and progesterone level. And it was reported that estradiol (Walf and Frye, 2006; Walf et al., 2009), as well as the progesterone (Paris et al., 2014) have anti-anxiety effect. Therefore, further studies are needed to understand the effects of ELF-EMF on behavior.

5. Conclusion

In conclusion, our results suggested that prolonged exposure to ELF-EMF showed no effects on the behavior of the adult male rats, including the general behavior, anxiety like behavior, depression like behavior, spatial learning and memory, as well as...
as fear learning and memory, which suggested that exposure to ELF-EMF might be safe.
