hours (95% CI 11.5–24.6) for 8 hour stewardship coverage. When stewardship coverage was extended to 16 hours, the mean decrease in time to ASTEW-I with APS was 21.4 hours (95% CI 14.3–28.5). Both time differences were found to be statistically significant (P < 0.0001).

Conclusion. In a cohort of patients with Gram-negative bacteremia, when compared with ASTEW-I guided by APS significantly shortened the time to potential antimicrobial optimization. This improvement occurred even when antimicrobial stewardship support was limited to an 8 hour work day.

Session: 240. Stewardship: Impact of Diagnostics
Saturday, October 7, 2017: 12:30 PM

Background. In order to detect multidrug resistant (MDR) bacteria, our laboratory routinely performs direct susceptibility (DS) testing from positive blood cultures. We conducted a prospective study to determine the accuracy, reporting time (RT), and antimicrobial stewardship impact of DS testing for Gram-negative bacilli (GNB) positive blood cultures.

Methods. From March – December 2016, first time positive blood cultures for GNB were included in the study. Broth from positive blood culture bottles was inoculated to standard media, as well as to Mueller-Hinton agar with ceftoxin (FOX), amoxicillin-clavulanic acid (AMC), ceftriaxone (CRO), ceftazidime (CAZ), ciprofloxacin (CIP) and meropenem (MEM) disks. The CRO and CAZ were adjacent to the AMC disk, which enabled detection of zone-enhancement with extended-spectrum β-lactamase (ESBL) producing organisms. CLSI breakpoints were used to guide interpretations of the DS results. Antibiotic therapy changes, made based on verbal reporting of DS results, were recorded. In order to determine RT, the following time points were recorded: blood culture positivity, reading of DS, and reporting of standardized susceptibilities (SS).

Results. There were 105 unique, monomicrobial cultures consisting of: E. coli (N = 61), Klebsiella sp. (N = 15), Enterobacter sp. (N = 9), Proteus sp. (N = 5), Pseudomonas aeruginosa (N = 5), and 10 other miscellaneous GNB. RT was reduced from 38 to 7 hours, for SS and DS, respectively. For species with CLSI breakpoints (101 isolates), the major antimicrobial susceptibility test was 30%, respectively; 17% of isolates were DS-intermediate and SS-susceptible (minor error). CIP disk testing identified all resistant isolates correctly (N = 21), as did MEM (N = 7). Resistance to CRO/CAZ was correctly identified in 26/27 isolates. DS results changed antibiotic management for 21 patients. Antibiotics were narrowed for 7 patients, and treatment was expanded for 16 patients. For these patients, DS results were available 24 hours before SS.

Conclusion. DS testing is an accurate and rapid method to detect MDR GNB blood culture pathogens and facilitates the optimization of antimicrobial therapy. A relatively high rate of minor errors was detected due to DS disks testing in the intermediate zone for isolates ultimately identified as susceptible by SS.

2136. Effect of the Methicillin-Resistant Staphylococcus aureus Nasal Polymerase Chain Reaction on Vancomycin Days and Clinical Outcomes in Pneumonia Patients

Natalie Hendon, PharmD and Brian Nelson, PharmD

New York Presbyterian Hospital, New York, New York

Session: 240. Stewardship: Impact of Diagnostics
Saturday, October 7, 2017: 12:30 PM

Background. Previous studies have demonstrated that the methicillin resistant Staphylococcus aureus (MRSA) nasal polymerase chain reaction (PCR) assay has a high negative predictive value for MRSA pneumonia, and that a negative result may be used to guide antibiotic de-escalation. Despite increasing use in clinical practice, limited data exist regarding the impact of nasal MRSA testing on the duration of MRSA-directed therapy and patient outcomes. This study evaluated the effect of the MRSA nasal PCR result on vancomycin days and clinical outcomes in patients treated for pneumonia with empiric vancomycin therapy.

Methods. A retrospective study of adult inpatients with an MRSA nasal PCR assay ordered between January 2015 and September 2015 was conducted. Patients with confirmed or presumed pneumonia and who were treated with empiric vancomycin therapy were included. Outcomes were compared for patients with a negative vs. a positive MRSA nasal PCR result. The primary outcome was the number of days of vancomycin therapy. Secondary outcomes included restart of vancomycin within 7 days, length of hospitalization, 30-day readmission, 30 day mortality, and predictive value of the MRSA PCR assay. Analyses were performed for the overall cohort and a propensity score-matched cohort.

Results. 324 patients were included. In the overall cohort, the median duration of vancomycin therapy was 3 (interquartile range [IQR] 2–6) days in the negative MRSA nasal PCR group (n = 282) and 6 (IQR 4–9) days in the positive nasal PCR group (n = 42), P < 0.01. In the propensity score-matched cohort, the median number of vancomycin days was 3 (IQR 2–5) and 5 (IQR 4–8.5) in the negative (n = 137) and positive (n = 39) nasal PCR groups, respectively, P < 0.01. This difference persisted in an additional analysis of only patients with no positive respiratory cultures. No significant differences were observed in any secondary outcomes. The MRSA PCR assay demonstrated a positive predictive value of 45% and a negative predictive value of 98%.

Conclusion. A negative MRSA nasal PCR correlated with fewer days of vancomycin therapy without negatively impacting other clinical outcomes. The use of the MRSA nasal PCR assay may reduce the duration of MRSA-active therapy in PCR-negative patients.

Methods. We conducted a retrospective analysis of candidemia cases at the UAB Medical Center in 2015–16. T2C testing was introduced in January 2016. We compared outcomes among patients prior to and following the implementation of routine T2C testing. The focus of the study was to gather data on T2C time to initiation of therapy (TTT), and overall use of echinocandin patterns during the study period utilizing days of therapy (DOT) /1000 pt days as a parameter.

Results. In 2015 and 2016, 100 patients and 138 patients with candidemia, respectively, were included in the analysis. In 2016, there were 354 T2C valid results; 36 (10.2%) were positive and 318 (89.8%) were negative. The TTT for all candidemic patients in 2015 was 2.02 days vs 1.15 days for candidemic patients in 2016, including all who were blood culture(BC)+ and/or T2C+ (P < 0.0001). For patients with candidemia in 2016, TTT in the T2C + BC+ group vs those in whom only BC+ was 0.99 days and 1.69 days, respectively (P < 0.00001). Comparing results for 2015 and 2016, we observed echinocandin (Echin) usage of 15.1 and 17.8 DOT/1000 pt days, respectively.

Conclusion. We observed a significant decrease in the TTT for candidemic patients since introduction of the T2C. These results suggest that rapid identification of candidemia may be an important tool for AFT stewardship. We hypothesize that other factors, such as the updated IDSA Treatment Guidelines for Candidiasis and increased attention to the early intervention for sepsis campaign, may have influenced the use of Echin, and is supported by the observation that along with the decrease in TTT, we observed a slight increase in the DOT/1000 pt days between 2015 and 2016, suggesting more liberal use of empiric Echin.

2138. Effect of Rapid Molecular Diagnostic Testing and Antimicrobial Stewardship on Antimicrobial Therapy of Respiratory Infections

Thomas M. FIDSA, MD, FCP1, FCCP2, FCCM2, FCCP3, FACP2, FCCP4, Paul Politi, PharmD, FCP5, Michael J. Tan, MD, FACP, FIDSA6, and George Kallstrom, PhD7

Summa
vancomycin levels (median 0 vs. 1, P = 0.33) were similar before and after assay implementation.

**Conclusion.** There was a reduction in time to optimal antibiotic therapy after implementation of the PBP2a assay driven by changes in SSTI regimens but not pneumonia regimens. Incorporation of a rapid test to differentiate MSSA from MRSA be a useful addition to antibiotic stewardship initiatives to optimize therapy for patients with MSSA infection.

### 2140. Trends of Device Utilization Rates in Intensive Care Units During 10 Years in South Korea: Results from the Korean National Healthcare-Associated Infections Surveillance System

**Background.** Device-associated healthcare-associated infection (DA-HAI) is an important issue related to safety of patients. It is important to reduce unnecessary device utilization in order to decrease DA-HAI rates. Therefore, we investigate to the time trend of device utilization (DU) rates and DA-HAI rates to analyzed collected data for 10 years through the Korean National Healthcare-associated Infections Surveillance System (KONIS) which is voluntarily participating in hospitals.

**Methods.** We investigate the time trend of DU rates and DA-HAI rates from 2006 through 2015 in KONIS participating intensive care units (ICUs). DA-HAI rates were calculated as the numbers of infected per 1,000 catheter-days and DU were calculated as a ratio of device-days to patient-days. The pooled incidences of DUs and DA-HAI rates were calculated for each year of participation.

**Results.** Data were collected on 5,325,176 catheter-days and 6,358,829 patient-days in the 190 participating ICUs between July 2006 and June 2016. From 2006 to 2015, year-wise ventilator utilization ratio (V-UR) per 1000 patients-days increased significantly from 0.40 to 0.454 (F = 6.27, P < 0.0001), year-wise urinary catheter utilization ratio (UC-UR) show gradually increased trend from 0.83 to 0.84 but non-significant (F = 1.66, P = 0.095). Year-wise c-line utilization ratio (CL-UR) was gradually decreased non-significantly from 0.55 to 0.52 (F = 1.62, P = 0.1059). In subgroup analysis, Medical ICU (F = 2.79, P = 0.0034) or hospital with more than 900 beds (F = 3.07, P = 0.0015) related to increased significantly V-UR. Rate of ventilator associated pneumonia significantly decreased from 3.48 in 2006 to 1.00 in 2015 (per 1000 ventilator days, F = 27.62, P < 0.0001). Also, rates of cather associated UTI and c-line associated blood stream infection significantly decreased from 1.85 to 0.88 (per 1000 catheter-days, F = 10.14, P < 0.0001) and from 3.40 to 2.20 (per 1000 catheter-days, F = 7.07, P < 0.0001).

**Conclusion.** In Korea, all of the DA-HAIs have shown a significant reduction in the last 10 years, however V-HAUs have year-wise significantly increased trend for past 10-years, also UC-UR and CL-UR have not decreased trend significantly. We need effort to make reduction of device utilization rates.
