A small scale study on the effects of oral administration of the β-glucan produced by 
Aureobasidium pullulans on milk quality and cytokine expressions of Holstein cows, and on 
bacterial flora in the intestines of Japanese black calves

Abstract

Background: The β-(1 → 3),(1 → 6)-D-glucan extracellularly produced by Aureobasidium pullulans exhibits immunomodulatory activity, and is used for health supplements. To examine the effects of oral administration of the β-(1 → 3),(1 → 6)-D-glucan to domestic animals, a small scale study was conducted using Holstein cows and newborn Japanese Black calves.

Findings: Holstein cows of which somatic cell count was less than 3 x 10^5/ml were orally administered with or without the β-(1 → 3),(1 → 6)-D-glucan-enriched A. pullulans cultured fluid (AP-CF) for 3 months, and the properties of milk and serum cytokine expression were monitored. Somatic cell counts were not significantly changed by oral administration of AP-CF, whereas the concentration of solid non fat in the milk tended to increase in the AP-CF administered cows. The results of cytokine expression analysis in the serum using ELISA indicate that the expressions of tumor necrosis factor-α (TNF-α) and interleukin (IL)-6 in all cows which were orally administered with AP-CF became slightly lower than that of control cows after the two-month treatment. On the other hand, IL-8 expression tended to indicate a moderately higher level in all treated cows after the three-month administration of AP-CF in comparison with that of the control cows. Peripartum Japanese Black beef cows and their newborn calves were orally administered with AP-CF, and bacterial flora in the intestines of the calves were analyzed by T-RFLP (terminal restriction fragment length polymorphism). The results suggest that bacterial flora are tendentiously changed by oral administration of AP-CF.

Conclusions: Our data indicated the possibility that oral administration of the β-(1 → 3),(1 → 6)-D-glucan produced by A. pullulans affects cytokine expressions in the serum of Holstein cows, and influences bacterial flora in the intestines of Japanese Black calves. The findings may be helpful for further study on the efficacies of oral administration of β-(1 → 3),(1 → 6)-D-glucans on domestic animals.

Findings

Background

β-(1 → 3)-D-glucans produced by mushrooms, fungi and yeast are known to exhibit immunomodulating activity [1], and some beneficial effects of the β-(1 → 3)-D-glucans for cancer [2-4] and allergy [4,5] have been reported. A black yeast, *Aureobasidium pullulans* extracellularly produces β-(1 → 3)-D-glucan under a certain condition [6]. *A. pullulans* produces a β-(1 → 3)-D-glucan in a viscous water-soluble form, and in its structural feature, the β-(1 → 3)-D-glucan is known to be highly branched with β-(1 → 6)-glycosidic bonds [7,8]. The β-(1 → 3),(1 → 6)-D-glucan-containing *A. pullulans* cultured fluid is permitted as a food additive in many countries, and is used in health supplements. The β-(1 → 3),(1 → 6)-D-glucan produced by *A. pullulans* also exhibits immunomodulating activity and beneficial effects for various diseases just as the β-(1 → 3)-D-glucans derived from other organisms do [9-12]. The beneficial effect of oral administration of the β-(1 → 3),(1 → 6)-D-glucan produced by *A. pullulans* on health is believed not only to apply to humans, but also to animals. Thus, the β-(1 → 3),(1 → 6)-D-glucan-containing food supplements are also provided for pets. However, the effects of oral administration of the β-(1 → 3),(1 → 6)-D-glucan to domestic animals have not been well evaluated.

In this study, Holstein cows and Japanese Black calves were used to investigate the effect of oral administration

---

**Figure 1** The effects of oral administration of the β-(1 → 3),(1 → 6)-D-glucan on somatic cell count and solid non fat in the milk of Holstein cows. (A, B) Milk-producing Holstein cows were orally administered the β-(1 → 3),(1 → 6)-D-glucan-enriched *A. pullulans* cultured fluid (AP-CF) for three months, and then the somatic cell count (A) and solid non fat (B) in the milk were monitored every month. Milk produced from untreated cows was used as a control. The diagnoses of individual milk are indicated with a bar graph, and the line graph represents the mean. (C) The result of the same experiment with panel B conducted at other farms. A partially purified β-(1 → 3),(1 → 6)-D-glucan was used for this experiment.
of the β-(1 → 3),(1 → 6)-D-glucan produced by A. pullulans on domestic animals. The effects of this on the quality of milk, on cytokine expression profiles and on bacterial flora in the intestine were evaluated.

Methods

Cattle

In total, 15 Holstein cows, 8 Japanese Black peripartum beef cows, and their 8 new born calves in collaborating farms were used in this study. The β-(1 → 3),(1 → 6)-D-glucan produced by A. pullulans was administered as cattle feed. The β-(1 → 3),(1 → 6)-D-glucan has been approved as a cattle feed in Japan. All experiments in this study were conducted as part of daily management of cattle in the farms, and were performed after obtaining approval from the owners of the cattle. Hence, all procedures which involved contact with cattle, such as blood sampling and feces sampling, were performed by veterinarians as medical activities for daily management of the animals' health. This study did not require ethical approval in Japan. However, all experiments were conducted in consideration of the animals' welfare.

Preparation of A. Pullulans-cultured fluid (AP-CF) and partial purified β-(1 → 3),(1 → 6)-D-glucan

A. pullulans was grown at 24.5°C for 10 days, in a medium containing rice bran and sucrose, as a nitrogen and a carbohydrate source respectively. After the cultured medium was heated at 90°C for 30 min, the heat-sterilized cultured medium was used as AP-CF in this study.

The purified β-(1 → 3),(1 → 6)-D-glucan was prepared from the water soluble fraction of A. pullulans cultured fluid by ultrafiltration (a cut-off molecular weight of 200,000; Advantec, Tokyo, Japan). This fraction is assumed to be minimally containing other compounds, such as mono- and oligo-saccharides, nucleotides, and soluble proteins.

Monitoring milk quality

The somatic cell counts and the concentrations of solid non fat in the milk were measured by the Tokachi Federation of Agricultural Cooperatives, Tokachi, Hokkaido, Japan (to evaluate the effects of orally administered AP-CF), and the Livestock Improvement Association of Japan, Tokyo, Japan (to evaluate the effects of orally administered purified β-(1 → 3),(1 → 6)-D-glucan).

Figure 2  The effects of oral administration of the β-(1 → 3),(1 → 6)-D-glucan on cytokine expressions in the serum of Holstein cows. Serum was sampled from the Holstein cows used in Figure 1A and B, and then the expressions of tumor necrosis factor-α (TNF-α, A), interleukin (IL)-6 (B), and IL-8 (C) in the serum were quantified by ELISA. The bar graphs indicate the quantification value of each serum, and the line graphs show the mean.
ELISA

Blood samples were collected using vacuum tubes from the Holstein cows by doctors of veterinary medicine. After the serum was separated by centrifugation, the serum expression levels of interleukin (IL)-6, interleukin-8 (also called CXCL-8) and TNF-α (tumor necrosis factor-α) were analyzed using commercially available ELISA kits (Cusabio Biotech, Wuhan, China) in accordance with the manufacturer’s protocols.

T-RFLP (terminal restriction fragment length polymorphism) analysis and construction of the dendrogram

T-RFLP analysis was performed as previously described [13,14]. The T-RFLP results were subjected to the cluster analysis using UPGMA (unweighted pair-group method with arithmetic mean). The dendrogram was constructed using a web-based program (DendroUPGMA; http://genomes.urv.es/UPGMA/) [15].

Results and discussion

The effects of oral administration of the β-(1 → 3),(1 → 6)-D-glucan on somatic cell count and solid non fat in the milk of Holstein cows

Initially, we examined the effect of oral administration of the β-(1 → 3),(1 → 6)-D-glucan on the quality of milk produced by Holstein cows. The lactating Holstein cows of which somatic cell count was less than 3 x 10⁵/ml were used for this experiment. The Holstein cows were orally administered with (n = 2) or without (n = 3) the β-(1 → 3), (1 → 6)-D-glucan-enriched A. pullulans-cultured fluid (AP-CF; 300 ml/cow, 0.42 g/dl β-(1 → 3),(1 → 6)-D-glucan) once a day for three months, and the somatic cell counts and solid non fat in the milk were monitored. The results show that the initial difference of somatic cell counts between the administered cows and the control cows was not significantly changed throughout the experiment (Figure 1A). On the other hand, after the three-month administration of AP-CF, the mean concentration of solid non fat in the milk from the administered cows was higher than that of the control cows, and the difference of the mean between the administered cows and the control cows increased (Figure 1B).

Similar results were obtained by an experiment using purified β-(1 → 3),(1 → 6)-D-glucan in other farms (Figure 1C). The Holstein cows were orally administered with (n = 5) or without (n = 5) the partially purified β-(1 → 3),(1 → 6)-D-glucan (80 ml/cow, 0.42 g/dl β-(1 → 3),(1 → 6)-D-glucan) for two months, and the concentrations of solid non fat in the milk were monitored. As shown in Figure 1C, the results show that the mean concentration of solid non fat in the milk from control cows decreased in June, while the purified β-(1 → 3),(1 → 6)-D-glucan administered cows had no decrease in concentration.

The data shown in Figure 1B and 1C indicate that oral administration of the β-(1 → 3),(1 → 6)-D-glucan does not seem to be effective for the cows producing milk which has a relatively high concentration of solid non fat (≥9.0%). However, the concentration of solid non fat showed a tendency to increase with oral administration of the β-(1 → 3),(1 → 6)-D-glucan to cows producing milk containing a relatively low concentration of solid non fat (<9.0%). The results may indicate the possibility that oral administration of the β-(1 → 3),(1 → 6)-D-glucan exhibits efficacy to improve the solid non fat of Holstein cow milk.

The evaluation of the effect on cytokine expressions in the serum by oral administration of the β-(1 → 3),(1 → 6)-D-glucan

To evaluate the effect of oral administration of the β-(1 → 3),(1 → 6)-D-glucan on cytokine expressions, blood samples were collected from the same Holstein cows used in Figure 1A and 1B, and the serum expression levels of

Figure 3 The experimental procedure to estimate the effects of the β-(1 → 3),(1 → 6)-D-glucan on bacterial flora in the intestines of Japanese Black calves. The amounts of AP-CF orally administered to the calves are indicated in Table 1.
interleukin (IL)-6, interleukin-8 (also called CXCL-8) and TNF-α (tumor necrosis factor-α) were analyzed by ELISA. Overall, the results show that the expressions of these inflammatory cytokines were not strongly affected by oral administration of AP-CF. However, after a two-month administration, TNF-α (Figure 2A) and IL-6 (Figure 2B) expressions in all cows which were orally administered with AP-CF became slightly lower than that of the control cows. On the other hand, the expression of IL-8 in all of the AP-CF administered cows was greater after a three-month administration than with that of the control cows. On the other hand, the expression of IL-8 in all of the AP-CF administered cows was greater after a three-month administration than with that of the control cows.

The effect of oral administration of the β-(1 → 3),(1 → 6)-D-glucan on bacterial flora in the intestines of Japanese black calves

β-(1 → 3),(1 → 6)-D-glucans are known to be dietary fiber, and basically not digestible for mammals. Therefore, there is a possibility that oral administration of the β-(1 → 3),(1 → 6)-D-glucan affects bacterial flora in the intestines of cattle. Thus, to investigate the effects of oral administration of the β-(1 → 3),(1 → 6)-D-glucan on bacterial flora in the intestine, T-RFLP (terminal restriction fragment length polymorphism) analysis of the feces was performed [13, 14]. This experiment was conducted with Japanese Black peripartum beef cows and the experimental procedure to estimate the effects of the β-(1 → 3),(1 → 6)-D-glucan on bacterial flora in the intestine is summarized in Figure 3. The prepartum Japanese Black cows were orally administered with (n = 4) or without (n = 4) AP-CF (300 ml/cow, 0.42 g/dl β-(1 → 3),(1 → 6)-D-glucan) once a day beginning 60 days before the parturition. Oral administration was continued throughout the experiment. After birth, the calves (n = 4 for each group) were orally administered with AP-CF once a day for 35 days. As shown in Table 1, the amount of AP-CF used for oral administration was adjusted depending on the body weight of calf. The feces of calves were collected at 3, 7, 14, 21, 28 and 35 days after birth, and then the bacterial flora in the intestines of the cows were analyzed by T-RFLP. Correspondence of

Figure 4 T-RFLP analysis of bacterial flora in the intestines of Japanese Black calves. The correspondence of operational taxonomic units (OTUs) to phylogenetic bacterial groups is listed in Table 2.
operational taxonomic units (OTUs) to phylogenetic bacterial groups is listed in Table 2. As shown in Figure 4, although there was great diversity of bacterial flora between individual calves, some tendencies were found after the 35-day administration of AP-CF. For instance, the population of the genus *Prevotella* (317-bp OTU) tended to increase in the calves administered with AP-CF in comparison with that of non-administered calves.

To clarify the effect of oral administration of the $\beta-(1 \rightarrow 3),(1 \rightarrow 6)$-D-glucan on bacterial flora, the cluster analysis of the T-RFLP results was performed using UPGMA (unweighted pair-group method with arithmetic mean). The results show that the T-RFLP results were separated into two clusters, and most of the cows administered with AP-CF belong to cluster 2 whereas most of the control cows belong to cluster 1 (Figure 5). This may suggest that oral administration of the $\beta-(1 \rightarrow 3),(1 \rightarrow 6)$-D-glucan tends to affect bacterial flora of the intestine.

In this study, we examined the effects of oral administration of the $\beta-(1 \rightarrow 3),(1 \rightarrow 6)$-D-glucan produced by *A. pullulans* to cattle using Holstein cows and Japanese Black calves, and its possible effects on solid non fat in milk, on expressions of cytokines, and on bacterial flora in intestine were shown. The differences of concentration of solid non fat in the milk (Figure 1B and 1C) and expression of cytokines in the serum (Figure 2) between the $\beta-(1 \rightarrow 3),(1 \rightarrow 6)$-D-glucan administered cows and the control cows were found after a two or three-month administration. This may suggest that the effects of oral administration of the $\beta-(1 \rightarrow 3),(1 \rightarrow 6)$-D-glucan on cattle do not immediately appear. The influence of oral administration of the $\beta-(1 \rightarrow 3),(1 \rightarrow 6)$-D-glucan on bacterial flora might explain the reason. Although the effect of the change of bacterial flora in the intestine by oral administration of the $\beta-(1 \rightarrow 3),(1 \rightarrow 6)$-D-glucan on health has not been clarified, the influence of bacterial flora is thought to be an important phenomenon to evaluate the effects of the $\beta-(1 \rightarrow 3),(1 \rightarrow 6)$-D-glucan.

Basically, the $\beta-(1 \rightarrow 3),(1 \rightarrow 6)$-D-glucan is not digested by enzymes secreted in mammals’ gastrointestinal tract. Thus, the $\beta-(1 \rightarrow 3),(1 \rightarrow 6)$-D-glucan is thought to work as a soluble dietary fiber in humans when taken as a food. On the other hand, in cattle, the orally administered $\beta-(1 \rightarrow 3),(1 \rightarrow 6)$-D-glucan would not only work as a soluble dietary fiber, it would have other effects. In ruminants including cattle, commensal microorganisms in the rumen are important in helping ruminant animals to gain nutrients from their food. This digestion mechanism for cellulose metabolism is thought to be important to understand the effects of oral administration of the $\beta-(1 \rightarrow 3),(1 \rightarrow 6)$-D-glucan to cattle. It is known that some fungi, yeasts, and bacteria have $\beta-(1 \rightarrow 3)$-D-glucanases which are able to digest the $\beta-(1 \rightarrow 3),(1 \rightarrow 6)$-D-glucan. Therefore, the orally administered $\beta-(1 \rightarrow 3),(1 \rightarrow 6)$-D-glucan may affect the growth of certain bacterial strains which are able to use the $\beta-(1 \rightarrow 3),(1 \rightarrow 6)$-D-glucan as a nutrient, and this may influence the formation of bacterial flora in the intestine. In addition, the enhancement of $\beta-(1 \rightarrow 3)$-D-glucanases activity may affect the production of oligosaccharides and glycoproteins from foods in the rumen. Thus, in cattle, the orally administered $\beta-(1 \rightarrow 3),(1 \rightarrow 6)$-D-glucan is thought to exhibit the effects through
more complex mechanisms in comparison with those in humans. Although our data shown in this study are suggestive, we believe that our data are helpful for further study on the effects of oral administration of β-(1→3), (1→6)-D-glucans on domestic animals. More large-scale and long-term studies are required to establish the efficacy of oral administration of the β-(1→3), (1→6)-D-glucan to maintain the health of domestic animals.
