RNAi is a powerful tool to target the insect genes involved in host-pest interactions. Key insect genes are the choice for silencing to achieve pest derived resistance where resistance genes are not available in gene pool of host plant. In this study, an attempt was made to determine the effect of dsRNA designed from two genes *Cytochrome P450 derivative* (CYP6) and *Aminopeptidase N* (APN) of rice yellow stem borer (YSB) on growth and development of insect. The bioassays involved injection of chemically synthesized 5′ FAM labeled 21-nt dsRNA into rice cut stems and allowing the larvae to feed on these stems which resulted in increased mortality and observed growth and development changes in larval length and weight compared with its untreated control at 12–15 days after treatment. These results were further supported by observing the reduction in transcripts expression of these genes in treated larvae. Fluorescence detection in treated larvae also proved that dsRNA was readily taken by larvae when fed on dsRNA treated stems. These results from the present study clearly show that YSB larvae fed on dsRNA designed from *Cytochrome P450* and *Aminopeptidase N* has detrimental effect on larval growth and development. These genes can be deployed to develop YSB resistance in rice using RNAi approach.

INTRODUCTION

The rice yellow stem borer (YSB), *Scirpophaga incertulas* (Lepidoptera: Crambidae), is a widely distributed and destructive insect that causes significant yield losses to an extent of 10–90% by feeding on rice crop at all stages (Bandong and Litsinger, 2005). The YSB larvae that enter inside the stem cause death of the central shoot known as “dead hearts” at vegetative stage and unfilled panicles known as “white heads” at reproductive stage (Pathak and Khan, 1994). There are no resistant sources available for this deadly pest in cultivated rice germplasm (Brar and Khush, 1997). Although the option of expression of cry genes from *Bacillus thuringiensis* (Bt) is available, development of insect resistance in field has become one of the long standing issue with Bt food crops (Tabashnik et al., 2013). Given these circumstances, silencing of YSB genes through RNAi is a powerful tool to target the insect genes involved in host-pest interactions. Key insect genes are the choice for silencing to achieve pest derived resistance where resistance genes are not available in gene pool of host plant. In this study, an attempt was made to determine the effect of dsRNA designed from two genes *Cytochrome P450 derivative* (CYP6) and *Aminopeptidase N* (APN) of rice yellow stem borer (YSB) on growth and development of insect. The bioassays involved injection of chemically synthesized 5′ FAM labeled 21-nt dsRNA into rice cut stems and allowing the larvae to feed on these stems which resulted in increased mortality and observed growth and development changes in larval length and weight compared with its untreated control at 12–15 days after treatment. These results were further supported by observing the reduction in transcripts expression of these genes in treated larvae. Fluorescence detection in treated larvae also proved that dsRNA was readily taken by larvae when fed on dsRNA treated stems. These results from the present study clearly show that YSB larvae fed on dsRNA designed from *Cytochrome P450* and *Aminopeptidase N* has detrimental effect on larval growth and development. These genes can be deployed to develop YSB resistance in rice using RNAi approach.

interference (RNAi) by inactivating the key insect genes leading to aberration in pest growth and metabolism (Yang et al., 2011) offers an alternative. RNAi is sequence-specific gene silencing at the post-transcription level, induced by double stranded RNA (dsRNA; Fire et al., 1998; Hamilton et al., 2002). Down regulation of the expression of specific target genes through RNAi has been widely used for genetic research in several insects (Price and Gatehouse, 2008). However, selection of crucial genes which have an important role in insect life cycle for a specific insect is still a challenge (Kola et al., 2015).

Cytochrome P450 monoxygenases (cytochrome P450s) are found in virtually all living organisms. It plays an important role in the metabolism of xenobiotics such as drugs, pesticides, and plant toxins (Scott, 2008). In insects, cytochrome P450s play a predominant role in the metabolism of insecticides, which often results in the development of insecticide resistance in insect populations (Zhou et al., 2010). Most insect cytochrome P450 genes belong to microsomal CYP4, CYP6, CYP9, CYP28, CYP321, and mitochondrial CYP12 families which have been associated with detoxification processes allowing the insect to become tolerant or resistant to insecticides or host plant allelochemicals (Guo et al., 2011). Aminopeptidase N (APN) is a member of metallo enzymes present in larvae midgut of lepidopteran insects. It plays an important physiological role in dietary protein digestion (Marchler-Bauer et al., 2015). Inhibitory activity in the midgut can result in detrimental effect on larval growth, development, and lead to larval mortality (Reed et al., 1999). APNs are mainly studied for their role as receptors in Cry toxin-induced pathogenesis in insects (Bravo et al., 2007). Expression of APNs was found in midgut and malphigian tubules (Wang et al., 2005). RNAi mediated silencing of CYP6AE14 (Cytochrome P450 derivative) and APN in other lepidopteran insects like Helicoverpa armigera, Plutella xylostella, Achaea janata, and Spodoptera litura resulted in significant down-regulation of corresponding transcript and protein expression causing larval growth arrest and mortality and development of lethal larval-pupal intermediates (Rajagopal et al., 2002; Mao et al., 2007; Sivakumar et al., 2007; Bautista et al., 2009; Ningshen et al., 2013).

The present work was aimed to examine the effect of dsRNA molecules on silencing of YSB genes CYP6 and APN by feeding larvae on dsRNA treated cut stems. The dsRNAs fed larvae were examined to see the effect of silencing of these genes on insect growth and metabolism. Our bioassays simulated the in vivo mechanism of gene silencing and showed that dsRNA molecules can be taken up through the normal dietary path of YSB. Further, the target gene expression level was examined in control and dsRNA fed larvae which suggested silencing of the corresponding gene of YSB which is the first RNAi approach for YSB.

**MATERIALS AND METHODS**

**Design of Double Stranded RNA and Prediction of Off Targets**

To clone cDNAs of CYP6 and APN genes, a total of 48 corresponding sequences of CYP6 gene were downloaded from lepidopteron database, NCBI. Out of these, 10 sequences could find near homologies which were used for designing three primers. Similarly, to clone APN, total 47 sequences were downloaded from lepidopteron database, NCBI. Out of these, 25 sequences showed near homologies which were used to design two sets of primers from the conserved region through online tool (http://primer3.ut.ee/). Using these primers 750 bp cDNA of CYP6 and 728 bp cDNA for APN were cloned from YSB and submitted to Genbank (CYP6: KC904274, APN: KF290773). These YSB cDNA sequences were used for identification of siRNA hotspots and dsRNAs were designed based on the Reynolds rules (Reynolds et al., 2004). The designed dsRNA for CYP6 sense strand was 5'-AGUUUGAGAAUGAAGACUGA-3' and the antisense was 3'-UCAACUCUUACUUACUGACU-5' which had high Reynolds score of six out of eight. The similar strategy was followed for designing dsRNA from APN gene, the designed dsRNA sense strand sequence was 5'-GACGACGUAACUUACAUAC-3' and the antisense was 3'-UCUCGCGCAUGAAGUAGA-5' which had high Reynolds score eight out of eight. Care was taken for designed dsRNA not to have any unintended off targets, which was apparent by doing BLAST search. The designed dsRNAs were also tested in in silico to ascertain the fulfillment of different parameters for maximum silencing by using siMAX siRNA design tool (https://www.eurofinsgenomics.eu/en/dna-rna-oligonucleotides/custom-rna-oligos/simax-sirna.aspx). The selected dsRNA were chemically synthesized at Eurofins Genomics GmbH, Germany by attaching FAM (5’carboxy fluorescein) at 5’ position (Figure 1A).

**Bio Assay**

Adult moths of YSB were collected from the rice field at Indian Institute of Rice Research (IIRR), and released on susceptible cv. TN1 plants in glasshouse for egg laying. These egg masses were collected and transferred into plastic vials for hatching. The neonate larvae that hatched from a single egg mass were released on to ~8 cm long TN1 stems and reared at 25 ± 2°C for 3 days (Padmakumari et al., 2013). For in vitro cut stem bioassay, fresh TN1 cut stems (~8 cm) were placed in petri plate with moistened filter paper. For standardization of optimum concentration of dsRNA required for assay, three different concentrations i.e., 10, 20, and 30 pM of dsRNA were chosen. The dsRNA was injected into cut stems using small insulin syringe with volume of 30 µl per stem. Buffer (1×) of dsRNAs was used as control. The cut stems were kept at room temperature for 1 h for dsRNA to spread completely within the stem. On each treated cut stem, three larvae of 3 day old were released with the help of a soft paint brush. The insects were reared at 25 ± 2°C, 65%RH and 16:8 h (L: D). The optimized 30 pM concentration of dsRNA was used to determine its effect on larva, initially the experiment was carried out with different dsRNA concentration viz., 10, 20, 30, and 40 pM. (Figures showing the effect of these concentrations on YSB were submitted as Supplementary Material). We found that the response was good at 30 pM. Hence in all the experiments we used 30 µl of 30 pM dsRNA per 8 cm cut stem to evaluate the effect on the target insect. Each bioassay was carried with 15 stems in three replication (N = 45) and each experiment repeated twice to obtain uniform results. Various parameters like

Frontiers in Physiology | www.frontiersin.org 2 February 2016 | Volume 7 | Article 20
insect molting, abnormal morphological changes in the larval growth and length, and survival were observed at 6, 12, 15 days after treatment (DAT). At each time interval, three samples (nine larvae) were selected for observation by opening stems through destructive sampling. The dead larvae were dissected to observe under fluorescent microscope (Olympus CH40, Japan).

**Effects of dsRNA on YSB Larval Growth and Development**

**Larval Mortality**
The mortality of larvae was recorded by opening the cut stems under a microscope at 3 day intervals before changing on to fresh treated stems. The number of surviving larvae per concentration of dsRNA was recorded at different time intervals of 6, 12, and 15 days after treatment. The mortality of the larvae in both treated and untreated stems were recorded.

**Larval Weight and Length**
Reduction in larval weight was obtained by calculating differences in the mean of larval weight in dsRNA treated samples with that of untreated control. Larval weight was measured in milligrams using an electronic balance and larval size with centimeter scale.

**Fluorescent Detection of dsRNA**
To confirm the dsRNA uptake by larvae which were fed on treated stems, fluorescence detection was conducted using a fluorescent microscope (Olympus CH40, Japan) in the range of 460–480 nm. To detect the dsRNA in whole larva as well as in the larval midgut, florescence was observed at 6, 12, and 15 days after treatment.

**Statistical Analysis**
Data on larval length, larval weight and percentage of larval mortality for CYP6 and APN were analyzed by factorial ANOVA using Statistix 8.1 (Analytical Software, 2005). We observed that variance of mortality among the time intervals was slight unequal, to remove this effect, percent mortality was arc sine transformed, this transformation was made following rules mentioned in Gomez and Gomez (1984).

**Determination of Silencing**
To detect the silencing of CYP6 and APN in treated larvae, total RNA was extracted using Trizol reagent from 4 mg of single larva. cDNA was synthesized according to manufacturer's instructions by using Prime Script™ cDNA Synthesis Kit (Takara, Japan) from the total RNA extracted at various time intervals. The Quantitative Real time PCR (qRT-PCR) reactions were carried out with SYBR Premix Ex TaqTM (Takara Bio INC, Japan) following the manufacturer's protocol using a Real time PCR LC-96 (Roche LightCycler® 96). The qRT-PCR primers were designed using the online tool Primer3 (http://primer3.u.t.ee/). The primers used were CYP6 Forward-GATTTCGATCGTGGTCGTGCTCG Reverse- CCGCTGGGTTGGGTAATTC and APN Forward- AAGATTCAAGAGCCTGGTGCTG Reverse- GAT GACTCTGCGTTGAGGCA. For internal control, endogenous genes 18s rRNA from the Lepidopteron database and β-Actin were used (Kumar et al., 2009). Standard qRT-PCR procedures were followed with annealing of 60°C for 30 s. The specificity of the PCR reactions was monitored with melting curve analysis and gel electrophoresis. The relative gene expression data were analyzed by LC96 qPCR and by using the 2−ΔΔCt method as described previously (Schmittgen and Livak, 2008).

**Effect of dsRNA on Pink Stem Borer (PSB)**
To check the specificity of RNAi effect and off-target effect of dsRNA, the designed dsRNAs were tested on rice pink stem borer (Sesamia inferens) through in vitro bioassay. Bioassays were performed as like YSB and observation were taken on larval length and weight. The data was analyzed statistically by T-test using Statistix 8.1 software (Analytical Software, 2005).

**RESULTS**

**Cloning of cDNAs from YSB and Designing dsRNA**
In this study, systematic efforts were made to demonstrate the silencing of CYP6 and APN genes in YSB through in vitro studies using rice cut stems injected with corresponding dsRNAs. cDNAs of CYP6 and APN were cloned, CYP6 cDNA of YSB showed 70% identity with Chilo suppressalis, 69% with Spodoptera, 64% with Helicooverpa, and only 69% with Rice Leaf roller Cnaphalocrocis medinalis. Similarly, APN of YSB showed 71% identity with Chilo suppressalis, 89% with Spodoptera, 82% with Helicooverpa, and very less 69% with Rice Leaf roller Cnaphalocrocis medinalis. Among the siRNA hotspot regions, the region which does not have any homology to the related species was selected to design 21-nucleotide dsRNA. The designed two dsRNA sequences did not match to the any of the related species as well with mammalian species available in Genbank which indicates that it does not have the off targets. The cut stem assay was designed...
so as to simulate a real time situation wherein the larva bore
the stem pieces and enter into stem. As YSB is a monophagous
pest of paddy, we used cut stems of TN1 (highly susceptible
variety) for standardization of dsRNA concentration. We found
30 pM concentration of dsRNA could effectively silence the
CYP6 and APN genes and showed reduced growth and development,
whereas, 10 and 20 pM concentration of dsRNA showed very less
effect on larval growth (Supplementary Figure 1).

**Effect of dsRNA on Growth and Development**

The dsRNA of CYP6 and APN had a pronounced effect
on growth and development of the larvae. Larvae fed with
dsRNA specific to the CYP6 and APN showed significant
inhibition of growth in a time dependent manner. Treated
larvae (dsRNA) showed significant reduction in growth and
development characters like larval length and weight compared
with untreated larvae at regular time intervals. Larvae fed on
CYP6 dsRNA showed maximum weight reduction (8 mg) at 12
DAT and minimum was at 6 DAT as compared to its untreated
control (Figure 2A). dsRNA designed from APN also showed
significant larval weight and length reduction compared to its
untreated larvae. The larval weight reduction was maximum
at 15 DAT (Figure 2B). There was a significant reduction in
larval length with increase in exposure to dsRNAs. Treated larvae
showed a mean reduction in length of 0.45 cm at 15 DAT, 0.3 cm
at 12 DAT, and 0.25 cm at 6 DAT compared to untreated control
larvae (Figures 2C,D).

**Effect of dsRNA on Larval Mortality**

Mortality of treated larvae in both dsRNAs increased from
6 to 15 DAT. The highest mortality rate of 74.95% was
observed at 12 DAT in CYP6 (Figure 2E) and 80% at 15 DAT
in APN treatment (Figure 2F; Supplementary Tables 1A,B).
Florescent microscope observation before and after the relea
of larvae in the treated and untreated stems confirms that the
dsRNA abundance and translocation within the injected stem
(Figures 1B,C; Supplementary Figure 2). CYP6 dsRNA fed larvae
showed the presence of fluorescence in larval midgut at 6,
12, 15 DAT and it increased with the time course which was
also proportional to the increase in larval mortality as well as decrease in larval weight (Figure 3A). Similarly, we found that fluorescence in larval midgut in APN dsRNA fed larvae was proportional to the effect on larval growth (Figure 3B). These observations indicate that the designed dsRNA were systemic in nature, and through oral feeding could reach the targets genes, bind to them, thus affecting the larval growth and development.

**Confirmation of Gene Silencing by qRT-PCR**

We have observed the reduction in the expression level of CYP6, APN in all the stages of dsRNA treated samples, whereas, maximum silencing was observed at 12 DAT in CYP6, and 15 DAT in case of APN. Quantitative RT–PCR revealed, CYP6 expression in treated larvae was reduced by 3.5, 3.0 fold in 12, 15 DAT, respectively. In case of APN, the fold change in gene expression was increased by reducing its expression 2.9, 5.6, 13.5 fold in 6, 12, and 15 DAT compared to the control larvae (Figures 4A,B). The reduction in transcript levels in treated samples correlated with bioassay data for CYP6 and APN genes. So these results demonstrated that both genes have key roles in maintaining YSB growth and development.

**Effect of dsRNA on PSB**

The PSB larvae were reared on the rice TN1 cut stems where YSB specific dsRNAs was injected into the stems. Interestingly, no abnormalities were observed in PSB larvae when fed on treated stems of both dsRNA. In APN dsRNA treatment, the PSB larval lengths were similar to that of untreated control at 6, 12, and 15 DAT. Larval weight (mg) was also similar to the control at 6 and 12 DAT. However, decrease in larval weight was observed at 15 DAT (30 ± 1.0 mg), which is significantly lower (P-value 0.0055) compared to untreated control (49.0 ± 1.0 mg) but larval mortality was not observed. Whereas, in case of CYP6 dsRNA, we did not observe any changes in larval length and weight between control and treatments at three different time intervals. (Supplementary Table 2). Interestingly, larvae were quite active in both the treatments and mortality was not at all observed (Supplementary Data Videos 1–3) and pupae were formed. This clearly indicates that, the designed dsRNAs are specific to the YSB and they did not show any abnormal effect on PSB (Figure 5).

**DISCUSSION**

The success of RNAi for insect control depends on identification of suitable genes for RNAi. The candidate gene should not only have insecticidal effects on the target pests, but also safe toward other organisms, natural enemies and human beings (Agarwal et al., 2012; Kola et al., 2015). The present study showed that RNAi technology is an effective strategy for silencing the key genes involved in the metabolic activities of YSB. RNAi-triggered gene suppression through uptake of dsRNAs has been reported for many insect species belonging to Coleoptera, Diptera, Hemiptera, Hymenoptera, Isoptera, Lepidoptera, and Orthoptera (Huvenne and Smagghe, 2010). In this study, two important genes viz., CYP6 and APN were selected based on their earlier successful reports of silencing in lepidopteron pests (Rajagopal et al., 2002; Mao et al., 2007; Sivakumar et al., 2007; Bautista et al., 2009; Crava et al., 2010; Yang et al., 2010; Zhang et al., 2011; Edi et al., 2014). The Cytochrome P450 monooxygenases are present in almost all organisms including insects. They play vital roles in hormone
Kola et al. RNAi Approach for YSB Management

FIGURE 4 | Relative expression fed on TN1 cut stems treated with CYP6-dsRNA and APN-dsRNA in an individual bioassays. ß-actin and 18 s were used as an internal controls (A) expression of CYP6 gene from larvae sampled at 6, 12, 15 days after treatment along with respective controls. (B) Expression of APN in 6, 12, 15 days after treatment along with respective controls.

regulation, metabolism of xenobiotics and in biosynthesis or inactivation of endogenous compounds (Kola et al., 2015; Yu et al., 2015). Similarly, Aminopeptidase N (APNs) is primarily involved in dietary protein digestion majorly located at the midgut epithelium. APNs are known to cleave a single amino acid residue from the N-terminus of oligopeptides, preferentially the neutral amino acids (Wang et al., 2005; Pigott and Ellar, 2007). As, these two genes are known to play very important role in insect growth and development (Mao et al., 2007; Ningshen et al., 2013), we selected them as a candidate for silencing in YSB. Wang et al. (2015) succeeded in silencing CYP6AB14 by injecting dsRNA derived from CYP6AB14 into S. litura and found reduced transcript levels of CYP6AB14 and increased developmental abnormalities and higher mortality rates. Zhang et al. (2013), also observed larval mortality and reduced growth in H. armigera upon larval feeding on dsRNA designed from CYP6B6. Similar results were also reported with transgenic expression of CYP6AE14 in tobacco and cotton (Hodgson et al., 1995; Mao et al., 2007, 2011). Recently, Jin et al. (2015) designed dsRNAs targeted to Chitin synthase (Chi), CYP6AE14, and V-ATPase genes and expressed in the tobacco chloroplasts for control of Helicoverpa and observed reduced transcription of target genes in the insect midgut and stunted larval growth. Silencing of APN1 was reported in Castor Semilooper, A. janata (Ningshen et al., 2013).

For successful design of dsRNAs, there is a need to identify the specific regions or motif of key pest genes. To attain this, for the first time partial length of two candidate genes, CYP6 and APN were cloned from the YSB through PCR based strategy. Though YSB belongs to lepidopteron family, CYP6 showed 69% identity and APN 82% identities with Helicoverpa indicating significant differences. The unique regions of two YSB genes were selected for designing dsRNA, following Reynolds rules (Reynolds et al., 2004). The higher scores with these principles suggest having more stability and greater silence effects (Horn et al., 2010). Much of the commercial software currently available for designing dsRNAs follow Reynolds rule, Ui-Tei
rule, Amarzguioui rule, and Tuschl rule (Naito and Ui-Tei, 2012). The dsRNAs designed in this study of CYP6 and APN genes had the highest score based on Reynolds rule, which might have positive influence of their higher expression. There were some reports of using long dsRNA for effective RNAi than small dsRNA for insects (Miller et al., 2012; Li et al., 2015), however, recent reports indicated the more effectiveness of small dsRNAs insect control (Kumar et al., 2009; Naito and Ui-Tei, 2012; Gong et al., 2013). Our designed dsRNA from CYP6 lies in the principle domain of CYP450 group of enzymes, which belongs to haem-thiolate proteins involved in the oxidative degradation of various compounds. This class of proteins has domains viz., haem-binding loop (with an absolutely conserved cysteine that serves as the 5th ligand for the haem iron), the proton-transfer groove and the absolutely conserved EXXR motif in helix K forms a principle domain. Similarly APN (zinc-dependent metallopeptidases) is a Type II integral membrane protease belongs to Gluzincin family (thermolsyin-like peptidases or TLPs), this family consists of several zinc-dependent metallopeptidases including M1 peptidases and know to consist of a small N-terminal cytoplasmic domain, a single transmembrane domain and a large extracellular ectodomain that contains the active site. The dsRNA designed is lies in the part of active site of this enzyme so we expect that it binds to the target effectively.

Generally insect bioassays have been carried out through introducing dsRNA into an organism by microinjection (Ghanima et al., 2007), soaking and oral feeding through artificial diet (Mao et al., 2007; Chen et al., 2008). Since, YSB is a monophagous pest and does not have artificial diet; we resorted to rearing on rice cut stems, so as to simulate a real time situation where larva bore the stem pieces and enter into stem. In earlier studies cut stem assay were used to assess the toxicity of various toxins and transgenics against YSB (Nayak et al., 1997; Nguyen Huu Ho et al., 2001; Ramesh et al., 2004; Padmakumari et al., 2013). We found lower concentration of dsRNA (30 nM) was effective for silencing of target genes. Kumar et al. (2009) also found that 50 nM concentrations were effective for silencing Acetyl cholinesterase (Ache) gene in H. armigera. Similarly, Bautista et al. (2009) reported that 250 ng dsRNA targeting CYP6BGI delivery through droplet feeding to 4th instar larvae of Helicoverpa greatly reduced the CYP6BGI expression. To track accurately the presence of dsRNA in various insect tissues, FAM was used to label the dsRNA and confirmed their systemicity in insect tissue. Earlier reports have indicated the use of fluorescent dyes like Fluoroscein isothiocyanate (FITC), Cyanine Cy-3, Cy-5, and FAM to track the movement and binding of dsRNA in the tissues (Urwin et al., 2002; Karim et al., 2010; Hui et al., 2011; Wuriyaghan et al., 2011; Bolognesi et al., 2012; Li et al., 2015).

Our results indicated the increase of YSB larval mortality rates in feeding assay with dsRNA of CYP6 and APN genes. Change in growth and developmental characters were observed from very early larval developmental stages by showing reduced larval growth (larval weight and length), delayed molting and led to death. Interestingly, none of the larvae entered into pupae form. We observed an increase in fluorescence signal with increase in time of exposure which indicates the signal amplification. These observations were correlated with qRT-PCR experiments data.

The designed dsRNA sequences did not match with mammals or related species which are present in GenBank and beneficial insects which suggests that the designed dsRNA molecules may be specific to target insect and may not have unintended effects. Further to make sure of specificity of these molecules, bioassays were carried out in PSB, another stem borer of rice. The results indicated that dsRNAs designed from CYP6 and APN did not showed significant effect on larval length and weight except in case of 15 DAT with APN treatment. Further investigations are required to fully understand the delayed response of APN treatment in PSB larval weight. There was no morality in both the cases, larvae were quite active completed their instars and entered in to the pupal stage. These results suggest that the YSB dsRNAs of CYP6 and APN genes could not find targets in PSB which further confirms that the designed dsRNAs were more specific to YSB.

In our study, we conclusively proved the key functions of Cytochrome P450 and Aminopeptidase N enzymes in various metabolic pathways of YSB such as normal growth and also its involvement in many stages of development. The present results strongly suggest that these CYP6 and APN genes can be potential targets for insect-control, and insect-resistant transgenic plants may be obtained through RNAi-mediated silencing of insect genes. The off-targeting study through in silico and in vivo showed that the designed dsRNA from these genes are highly specific to insects and do not have any unintended effects on other organisms.

**AUTHOR CONTRIBUTIONS**

Conceived and designed the experiment: MSM, SKM, KVSR, PR, APP, SMB, and VRB.

**ACKNOWLEDGMENTS**

The work was carried out with the grant (Grant BT/PR2468/AGr/36/701/2011 dt 23.05.2012) from Department of Biotechnology, Government of India. The authors are thankful to Director, IIRR for providing research facilities, Dr. P.C Latha, Scientist-IIRR for providing the fluorescent microscope and Dr. M. Sampath Kumar, Scientist-IIRR for providing the larvae of PSB.
