Abstract In a recent work (Feischl et al. in Eng Anal Bound Elem 62:141–153, 2016), we analyzed a weighted-residual error estimator for isogeometric boundary element methods in 2D and proposed an adaptive algorithm which steers the local mesh-refinement of the underlying partition as well as the multiplicity of the knots. In the present work, we give a mathematical proof that this algorithm leads to convergence even with optimal algebraic rates. Technical contributions include a novel mesh-size function which also monitors the knot multiplicity as well as inverse estimates for NURBS in fractional-order Sobolev norms.

1 Introduction

1.1 Isogeometric analysis

The central idea of isogeometric analysis (IGA) is to use the same ansatz functions for the discretization of the partial differential equation at hand, as are used for the representation of the problem geometry. Usually, the problem geometry $\Omega$ is represented in CAD by means of non-uniform rational B-splines (NURBS), T-splines, or hierarchical splines. This concept, originally invented in [32] for finite element methods (IGAFEM) has proved very fruitful in applications; see also the monograph [9].

Since CAD directly provides a parametrization of the boundary $\partial \Omega$, this makes the boundary element method (BEM) the most attractive numerical scheme, if applicable (i.e., provided that the fundamental solution of the differential operator is explicitly known). However, compared to the IGA literature, only little is found for isogeometric BEM (IGABEM). The latter has first been considered for 2D BEM in [36] and for 3D BEM in [40]. Unlike standard BEM with piecewise polynomials which is well-studied in the literature, cf. the monographs [39,41] and the references therein, the numerical analysis of IGABEM is widely open. We refer to [35,37,38,42] for numerical experiments, to [44] for fast IGABEM with $\mathcal{H}$-matrices, and to [31] for some quadrature analysis. To the best of our knowledge, a posteriori error estimation for IGABEM, however, has only been considered for simple 2D model problems in the recent own works [24,25]. The present work extends the techniques from standard BEM to non-polynomial ansatz functions. The remarkable flexibility of the IGA ansatz functions to manipulate their smoothness properties motivates the development of a new adaptive algorithm which does not only automatically adapt the mesh-width, but also the continuity of the IGA ansatz function to exploit the additional freedoms and the full potential of IGA. This is the first algorithm which simultaneously steers the resolution and the smoothness of the ansatz functions, and, it may thus be a first step to a full $hpk$-adaptive algorithm.

For standard BEM with discontinuous piecewise polynomials, a posteriori error estimation and adaptive mesh-refinement are well understood. We refer to [1,11,12] for weighted-residual error estimators and to [19,22] for recent overviews on available a posteriori error estimation strategies. Moreover, optimal convergence of mesh-refining adaptive algorithms has recently been proved for polyhedral boundaries [20,21,26] as well as smooth boundaries [27]. The work [2] allows to transfer these results to piecewise smooth boundaries; see also the discussion in the review article [8].

While this work focusses on adaptive IGABEM, adaptive IGA literature is considered, e.g., in [16,43]. A rigorous error and convergence analysis in the frame of adaptive IGA literature is first found in [5] which proves linear convergence for some adaptive IGA literature with hierarchical splines for the Poisson equation, and optimal rates are announced for some future work.

1.2 Model problem

We develop and analyze an adaptive algorithm for the following model problem: Let $\Omega \subset \mathbb{R}^2$ be a Lipschitz domain with $\text{diam}(\Omega) < 1$ and $\Gamma \subseteq \partial \Omega$ be a compact,
piecewise smooth part of its boundary with finitely many connected components. We consider the weakly-singular boundary integral equation

$$V \phi(x) := -\frac{1}{2\pi} \int_{\Gamma} \log|\mathbf{x} - \mathbf{y}| \phi(y) \, dy = f(x) \quad \text{for all } x \in \Gamma,$$

where the right-hand side $f$ is given and the density $\phi$ is sought. We note that (1.1) for $\Gamma = \partial \Omega$ is equivalent to the Laplace–Dirichlet problem

$$-\Delta u = 0 \quad \text{in } \Omega \quad \text{with} \quad u = f \quad \text{on } \Gamma, \quad \text{where } u := V \phi.$$

To approximate $\phi$, we employ a Galerkin boundary element method (BEM) with ansatz spaces consisting of $p$-th order NURBS. The convergence order for uniform partitions of $\Gamma$ is usually suboptimal, since the unknown density $\phi$ may exhibit singularities, which are stronger than the singularities in the geometry. In [24], we analyzed a weighted-residual error estimator and proposed an adaptive algorithm which uses this a posteriori error information to steer the $h$-refinement of the underlying partition as well as the local smoothness of the NURBS across the nodes of the adaptively refined partitions. It reflects the fact that it is a priori unknown, where the singular and smooth parts of the density $\phi$ are located and where approximation by nonsmooth resp. smooth functions is required. In [24], we observed experimentally that the proposed algorithm detects singularities and possible jumps of $\phi$ and leads to optimal convergence behavior. In particular, we observed that the proposed adaptive strategy is also superior to adaptive BEM with discontinuous piecewise polynomials in the sense that our adaptive NURBS discretization requires less degrees of freedom to reach a prescribed accuracy.

### 1.3 Contributions

We prove that the adaptive algorithm from [24] is rate optimal in the sense of [8]: Let $\mu_\ell$ be the weighted-residual error estimator in the $\ell$-th step of the adaptive algorithm. First, the adaptive algorithm leads to linear convergence of the error estimator, i.e., $\mu_{\ell+n} \leq C q^n \mu_\ell$ for all $\ell, n \in \mathbb{N}_0$ and some independent constants $C > 0$ and $0 < q < 1$. Moreover, for sufficiently small marking parameters, i.e. aggressive adaptive refinement, the estimator decays even with the optimal algebraic convergence rate. Here, the important innovation is that the adaptive algorithm does not only steer the local refinement of the underlying partition (as is the case in the available literature, e.g., [8,20,21,26,27]), but also the multiplicity of the knots. In particular, the present work is the first available optimality result for adaptive algorithms in the frame of isogeometric analysis. Additionally, we can prove at least plain convergence if the adaptive algorithm is driven by the Faermann estimator $\eta_\ell$ analyzed in [25] instead of the weighted-residual estimator $\mu_\ell$, which generalizes a corresponding result for standard adaptive BEM [23].

Technical contributions of general interest include a novel mesh-size function $h \in L^\infty(\Gamma)$ which is locally equivalent to the element length (i.e., $h|_T \simeq \text{length}(T)$ for all
elements $T$), but also accounts for the knot multiplicity. Moreover, for $0 < \sigma < 1$, we prove a local inverse estimate $\|h^\sigma \Psi\|_{L^2(\Gamma)} \leq C \|\Psi\|_{\tilde{H}^{-\sigma}(\Gamma)}$ for NURBS on locally refined meshes. Similar estimates for piecewise polynomials are shown in [15,29,30], while [3] considers NURBS but integer-order Sobolev norms only.

Throughout, all results apply for piecewise smooth parametrizations $\gamma$ of $\Gamma$ and discrete NURBS spaces. In particular, the analysis thus covers the NURBS ansatz used for IGABEM, where the same ansatz functions are used for the discretization of the integral equation and for the resolution of the problem geometry, as well as spline spaces and even piecewise polynomials on the piecewise smooth boundary $\Gamma$ which can be understood as special NURBS.

1.4 Outline

The remainder of this work is organized as follows: Sect. 2 fixes the notation and provides the necessary preliminaries. This includes, e.g., the involved Sobolev spaces (Sect. 2.2), the functional analytic setting of the weakly-singular integral equation (Sect. 2.3), the assumptions on the parametrization of the boundary $\Gamma$ (Sect. 2.4), the discretization of the boundary (Sect. 2.5), the mesh-refinement strategy (Sect. 2.6), B-splines and NURBS (Sect. 2.7), and the IGABEM ansatz spaces (Sect. 2.8). Section 3 states our adaptive algorithm (Algorithm 3.1) from [24] and formulates the main theorems on linear convergence with optimal rates for the weighted-residual estimator $\mu_\ell$ (Theorem 3.2) and on plain convergence for the Faermann estimator $\eta_\ell$ (Theorem 3.4). The linear convergence for the $\mu_\ell$-driven algorithm is proved in Sect. 4. The proof requires an inverse estimate for NURBS in a fractional-order Sobolev norm (Proposition 4.1) as well as a novel mesh-size function for B-spline and NURBS discretizations (Proposition 4.2) which might be of independent interest. The proof of optimal convergence behaviour is given in Sect. 5. In Sect. 6, we show convergence for the $\eta_\ell$-driven algorithm.

For the empirical verification of the optimal convergence behavior of Algorithm 3.1 for $\mu_\ell$- as well as $\eta_\ell$-driven adaptivity and a comparison of IGABEM and standard BEM with discontinuous piecewise polynomials, we refer to the numerous numerical experiments in our preceding work [24].

2 Preliminaries

2.1 General notation

Throughout, $|\cdot|$ denotes the absolute value of scalars, the Euclidean norm of vectors in $\mathbb{R}^2$, the measure of a set in $\mathbb{R}$ (e.g., the length of an interval), or the arclength of a curve in $\mathbb{R}^2$. The respective meaning will be clear from the context. We write $A \lesssim B$ to abbreviate $A \leq cB$ with some generic constant $c > 0$ which is clear from the context. Moreover, $A \simeq B$ abbreviates $A \lesssim B \lesssim A$. Throughout, mesh-related quantities have the same index, e.g., $N_\ell$ is the set of nodes of the partition $T_\ell$, and $h_\ell$ is the corresponding local mesh-width etc. The analogous notation is used for partitions $T_+\ell$ resp. $T_-\ell$ etc.
2.2 Sobolev spaces

For any measurable subset \( I_0 \subseteq \Gamma \), let \( L^2(I_0) \) denote the Lebesgue space of all square integrable functions which is associated with the norm \( \|u\|_{L^2(I_0)}^2 := \int_{I_0} |u(x)|^2 \, dx \).

We define for any \( 0 < \sigma \leq 1 \) the Hilbert space
\[
H^\sigma(I_0) := \{ u \in L^2(I_0) : \|u\|_{H^\sigma(I_0)} < \infty \},
\] (2.1)
associated with the Sobolev–Slobodeckij norm
\[
\|u\|_{H^\sigma(I_0)}^2 := \|u\|_{L^2(I_0)}^2 + |\partial \varphi u|_{H^\sigma(I_0)}^2,
\] (2.2)
with
\[
|\partial \varphi u|_{H^\sigma(I_0)}^2 := \left\{ \int_{I_0} \frac{\|u(x)-u(y)\|^2}{|x-y|^{1+2\sigma}} \, dy \, dx, \quad \text{for } 0 < \sigma < 1 \right\},
\] (2.3)
where \( \partial \varphi \) denotes the arclength derivative. For finite intervals \( I \subseteq \mathbb{R} \), we use analogous definitions. By \( \tilde{H}^{-\sigma}(I_0) \), we denote the dual space of \( H^\sigma(I_0) \), where duality is understood with respect to the extended \( L^2(I_0) \)-scalar product, i.e.,
\[
\langle u ; \phi \rangle_{I_0} = \int_{I_0} u(x)\phi(x) \, dx \quad \text{for all } u \in H^\sigma(I_0) \text{ and } \phi \in L^2(I_0).
\] (2.4)

We note that \( H^\sigma(\Gamma) \subset L^2(\Gamma) \subset \tilde{H}^{-\sigma}(\Gamma) \) form a Gelfand triple and all inclusions are dense and compact. Amongst other equivalent definitions of \( H^\sigma(I_0) \) are for example interpolation techniques. All these definitions provide the same space of functions but different norms, where norm equivalence constants depend only on \( I_0 \); see, e.g., the monographs [33,34] and the references therein. Throughout our proofs, we shall use the Sobolev–Slobodeckij norm (2.2), since it is numerically computable.

2.3 Weakly-singular integral equation

It is known [33,34] that the weakly-singular integral operator \( V : \tilde{H}^{-1/2}(\Gamma) \to H^{1/2}(\Gamma) \) from (1.1) is a symmetric and elliptic isomorphism if \( \text{diam}(\Omega) < 1 \) which can always be achieved by scaling. For a given right-hand side \( f \in H^{1/2}(\Gamma) \), the strong form (1.1) is thus equivalently stated by
\[
\langle V\phi ; \psi \rangle_{\Gamma} = \langle f ; \psi \rangle_{\Gamma} \quad \text{for all } \psi \in \tilde{H}^{-1/2}(\Gamma),
\] (2.5)
and the left-hand side defines an equivalent scalar product on \( \tilde{H}^{-1/2}(\Gamma) \). In particular, the Lax–Milgram lemma proves existence and uniqueness of the solution \( \phi \in \tilde{H}^{-1/2}(\Gamma) \). Additionally, \( V : L^2(\Gamma) \to H^1(\Gamma) \) is well-defined, linear, and continuous.
In the Galerkin boundary element method, the test space $H^{-1/2}(\Gamma)$ is replaced by some discrete subspace $X \subset L^2(\Gamma) \subset H^{-1/2}(\Gamma)$. Again, the Lax–Milgram lemma guarantees existence and uniqueness of the solution $\Phi \in X$ of the discrete variational formulation
\[(V \Phi; \Psi) = (f; \Psi)\quad\text{for all } \Psi \in X.\] (2.6)

Below, we shall assume that $X$ is linked to a partition $T$ of $\Gamma$ into a set of connected segments.

### 2.4 Boundary parametrization

Let $\Gamma = \bigcup_{i} \Gamma_i$ be decomposed into its finitely many connected components $\Gamma_i$. Since the $\Gamma_i$ are compact and piecewise smooth as well, it holds
\[
\|u\|_{H^{1/2}(\Gamma)}^2 = \sum_i \|u\|_{H^{1/2}(\Gamma_i)}^2 + \sum_{i,j, i \neq j} \int_{\Gamma_i} \int_{\Gamma_j} \frac{|u(x) - u(y)|^2}{|x-y|^2} \, dy \, dx \simeq \sum_i \|u\|_{H^{1/2}(\Gamma_i)}^2
\]

see, e.g., [25, Section 2.2]. The usual piecewise polynomial and NURBS basis functions have connected support and are hence supported by some single $\Gamma_i$ each. Without loss of generality and for the ease of presentation, we may therefore assume throughout that $\Gamma$ is connected. All results of this work remain valid for non-connected $\Gamma$.

We assume that either $\Gamma = \partial \Omega$ is parametrized by a closed continuous and piecewise two times continuously differentiable path $\gamma : [a, b] \to \Gamma$ such that the restriction $\gamma|_{[a, b]}$ is even bijective, or that $\Gamma \subset \not\subseteq \partial \Omega$ is parametrized by a bijective continuous and piecewise two times continuously differentiable path $\gamma : [a, b] \to \Gamma$. In the first case, we speak of closed $\Gamma = \partial \Omega$, whereas the second case is referred to as open $\Gamma \subset \not\subseteq \partial \Omega$.

For closed $\Gamma = \partial \Omega$, we denote the $(b-a)$-periodic extension to $\mathbb{R}$ also by $\gamma$. For the left and right derivative of $\gamma$, we assume that $\gamma'^L(t) \neq 0$ for $t \in (a, b)$ and $\gamma'^R(t) \neq 0$ for $t \in [a, b)$. Moreover we assume that $\gamma'^L(t) + c\gamma'^R(t) \neq 0$ for all $c > 0$ and $t \in [a, b]$ resp. $t \in (a, b)$. Finally, let $\gamma_L : [0, L] \to \Gamma$ denote the arclength parametrization, i.e., $|\gamma_L'^L(t)| = 1 = |\gamma_L'^R(t)|$, and its periodic extension. Elementary differential geometry yields bi-Lipschitz continuity
\[
C_{\Gamma}^{-1} \leq \frac{|\gamma_L(s) - \gamma_L(t)|}{|s - t|} \leq C_{\Gamma} \quad \text{for } s, t \in \mathbb{R}, \quad \text{with } \begin{cases} |s - t| \leq \frac{3}{4} L, \text{ for closed } \Gamma, \\ s \neq t \in [0, L], \text{ for open } \Gamma, \end{cases}
\] (2.7)

where $C_{\Gamma} > 0$ depends only on $\Gamma$. A proof is given in [28, Lemma 2.1] for closed $\Gamma = \partial \Omega$. For open $\Gamma \subset \not\subseteq \partial \Omega$, the proof is even simpler.
Let \( I \subseteq [a, b] \). If \( \Gamma = \partial \Omega \) is closed and \( |I| \leq \frac{3}{4}L \) resp. if \( \Gamma \subsetneq \partial \Omega \) is open, the bi-Lipschitz continuity (2.7) implies
\[
C_{\Gamma}^{-1}|u \circ \gamma_L|_{H^{1/2}(I)} \leq |u|_{H^{1/2}(\gamma_L(I))} \leq C_{\Gamma}|u \circ \gamma_L|_{H^{1/2}(I)}.
\]

(2.8)

2.5 Boundary discretization

In the following, we describe the different quantities which define the discretization.

**Nodes** \( z_j = \gamma(\tilde{z}_j) \in \mathcal{N}_\ast \). Let \( \mathcal{N}_\ast := \{z_j : j = 1, \ldots, n\} \) and \( z_0 := z_n \) for closed \( \Gamma = \partial \Omega \) resp. \( \mathcal{N}_\ast := \{z_j : j = 0, \ldots, n\} \) for open \( \Gamma \subsetneq \partial \Omega \) be a set of nodes. We suppose that \( z_j = \gamma(\tilde{z}_j) \) for some \( \tilde{z}_j \in [a, b] \) with \( a = \tilde{z}_0 < \tilde{z}_1 < \tilde{z}_2 < \cdots < \tilde{z}_n = b \) such that \( \gamma|_{[\tilde{z}_{j-1}, \tilde{z}_j]} \in C^2([\tilde{z}_{j-1}, \tilde{z}_j]) \).

**Multiplicity \#z_j and knots** \( \mathcal{K}_\ast, \hat{\mathcal{K}}_\ast \). Let \( p \in \mathbb{N}_0 \) be some fixed polynomial order. Each node \( z_j \) has a multiplicity \( \#z_j \in \{1, 2, \ldots, p + 1\} \) with \( \#z_0 = \#z_n = p + 1 \). This induces knots
\[
\mathcal{K}_\ast = (z_k, \ldots, z_k, \ldots, z_n, \ldots, z_n),
\]

(2.9)

with \( k = 1 \) resp. \( k = 0 \) and corresponding knots \( \hat{\mathcal{K}}_\ast := \gamma^{-1}|_{(a, b)}(\mathcal{K}_\ast) \) resp. \( \hat{\mathcal{K}}_\ast := \gamma^{-1}(\mathcal{K}_\ast) \) on the parameter domain \([a, b]\).

**Elements, partition** \( \mathcal{T}_\ast \) and \([T], [T_\ast]\). Let \( \mathcal{T}_\ast = \{T_1, \ldots, T_n\} \) be a partition of \( \Gamma \) into compact and connected segments \( T_j = \gamma(\tilde{T}_j) \) with \( \tilde{T}_j = [\tilde{z}_{j-1}, \tilde{z}_j] \). We define
\[
[T_\ast] := \{[T] : T \in \mathcal{T}_\ast\} \quad \text{with} \quad [T] := (T, \#z_{T, 1}, \#z_{T, 2}),
\]

(2.10)

where \( z_{T, 1} = z_{j-1} \) and \( z_{T, 2} = z_j \) are the two nodes of \( T = T_j \).

**Local mesh-sizes** \( h_{\ast,T}, \hat{h}_{\ast,T} \) and \( h_{\ast}, \hat{h}_{\ast} \). The arclength of each element \( T \in \mathcal{T}_\ast \) is denoted by \( h_{\ast,T} \). We define the local mesh-width function \( h_{\ast} \in L^\infty(\Gamma) \) by \( h_{\ast}|_{T} = h_{\ast,T} \). Additionally, we define for each element \( T \in \mathcal{T}_\ast \) its length \( \hat{h}_{\ast,T} := |\gamma^{-1}(T)| \) with respect to the parameter domain \([a, b]\). This gives rise to \( \hat{h}_{\ast} \in L^\infty(\Gamma) \) with \( \hat{h}_{\ast}|_{T} = \hat{h}_{\ast,T} \). Note that the lengths \( h_{\ast,T} \) and \( \hat{h}_{\ast,T} \) of an element \( T \) are equivalent, where the equivalence constants depend only on \( \gamma \).

**Local mesh-ratios** \( \hat{\kappa}_\ast \). We define the local mesh-ratio by
\[
\hat{\kappa}_\ast := \max \{\hat{h}_{\ast,T}/\hat{h}_{\ast,T'} : T, T' \in \mathcal{T}_\ast \text{ with } T \cap T' \neq \emptyset\}.
\]

(2.11)

**Patches** \( \omega_\ast(z), \omega_\ast(U), \omega_\ast(U), \text{ and } \bigcup \mathcal{U} \). For each set \( U \subseteq \Gamma \), we inductively define for \( m \in \mathbb{N}_0 \) (Fig. 1)
The patch \( \omega^\star_\alpha(z) \) of some node \( z \in \mathcal{N}_\star \) resp. the patch \( \omega^\star_\alpha(T) \) are illustrated in blue resp. green.

\[
\omega^m_\alpha(U) := \begin{cases} 
U & \text{if } m = 0, \\
\omega_\alpha(U) := \bigcup \{ T \in \mathcal{T}_\star : T \cap U \neq \emptyset \} & \text{if } m = 1, \\
\omega_\alpha(\omega^{m-1}_\alpha(U)) & \text{if } m > 1.
\end{cases}
\]

For nodes \( z \in \Gamma \), we abbreviate \( \omega^\star_\alpha(z) =: \omega^\star_\alpha([z]) \). For each set \( \mathcal{U} \subseteq [\mathcal{T}_\star] \), we define

\[
\bigcup \mathcal{U} := \bigcup \{ T \in \mathcal{T}_\star : [T] \in \mathcal{U} \},
\]

and

\[
\omega^m_\alpha(\mathcal{U}) := \omega^m_\alpha\left( \bigcup \mathcal{U} \right).
\]

### 2.6 Mesh-refinement

Suppose that we are given a deterministic mesh-refinement strategy \( \text{ref} (\cdot) \) such that, for each mesh \([T_\star]\) and an arbitrary set of marked nodes \( \mathcal{M}_\star \subseteq \mathcal{N}_\star \), the application \([T_\star]^+ := \text{ref}([T_\star], \mathcal{M}_\star)\) provides a mesh in the sense of Sect. 2.5 such that, first, the marked nodes belong to the union of the refined elements, i.e., \( \mathcal{M}_\star \subseteq \bigcup ([T_\star] \setminus [T_\star]^+) \), and, second, the knots \( \mathcal{K}_\star \) form a subsequence of the knots \( \mathcal{K}_+ \). The latter implies the estimate

\[
|([T_\star] \setminus [T_\star]^+)| \leq 2(|\mathcal{K}_+| - |\mathcal{K}_\star|),
\]

since \([T_\star] \setminus [T_\star]^+\) is the set of all elements in which a new knot is inserted and one new knot can be inserted in at most 2 elements of the old mesh, i.e., at the intersection of 2 elements.

We write \([T_\star]^+ \in \text{ref}([T_\star])\), if there exist finitely many meshes \([T_1], \ldots, [T_\ell]\) and subsets \( \mathcal{M}_j \subseteq \mathcal{N}_j \) of the corresponding nodes such that \([T_\star] = [T_1], [T_\star]^+ = [T_\ell], \) and...
\([T_j] \in \text{ref}([T_{j-1}], \mathcal{M}_{j-1})\) for all \(j = 2, \ldots, \ell\), where we formally allow \(m = 1\), i.e., \([T_*] = [T_i] \in \text{ref}([T_i])\).

For the proof of our main result, we need the following assumptions on \(\text{ref}(.\)\).

**Assumption 2.1** For an arbitrary initial mesh \([T_0] \in \mathbb{T}\) := \(\text{ref}([T_0])\), we assume that the mesh-refinement strategy satisfies the properties (M1)–(M3):

(M1) There exists a constant \(\tilde{\kappa}_{\text{max}} \geq 1\) such that the local mesh-ratios (2.11) are uniformly bounded

\[ \tilde{\kappa}_* \leq \tilde{\kappa}_{\text{max}} \quad \text{for all } [T_*] \in \mathbb{T}. \quad (2.13) \]

(M2) For all \([T_*], [T_+] \in \mathbb{T}\), there is a common refinement \([T_* \oplus T_+] \in \text{ref}([T_*]) \cap \text{ref}([T_+])\) such that the knots \(K_* \oplus K_+\) of \([T_* \oplus T_+]\) satisfy the overlay estimate

\[ |K_* \oplus K_+| \leq |K_*| + |K_+| - |K_0|. \quad (2.14) \]

(M3) Each sequence \([T_\ell] \in \mathbb{T}\) of meshes generated by successive mesh-refinement, i.e., \([T_j] = \text{ref}([T_{j-1}], \mathcal{M}_{j-1})\) for all \(j \in \mathbb{N}\) and arbitrary \(\mathcal{M}_j \subseteq \mathcal{N}_j\), satisfies

\[ |K_\ell| - |K_0| \leq C_{\text{mesh}} \sum_{j=0}^{\ell-1} |\mathcal{M}_j| \quad \text{for } \ell \in \mathbb{N}, \quad (2.15) \]

where \(C_{\text{mesh}} > 0\) depends only on \([T_0]\).

These assumptions are especially satisfied for pure \(h\)-refinement based on local bisection [1] as well as for the concrete strategy used in [24,25]. The latter strategy looks as follows: Let \([T_*] \in \mathbb{T}\). Let \(\mathcal{M}_* \subseteq \mathcal{N}_*\) be a set of marked nodes. To get the refined mesh \([T_+] := \text{ref}([T_*], \mathcal{M}_*)\), we proceed as follows:

(i) If both nodes of an element \(T \in T_*\) belong to \(\mathcal{M}_*\), the element \(T\) will be marked.
(ii) For all other nodes in \(\mathcal{M}_*\), the multiplicity will be increased if it is less or equal to \(p + 1\), otherwise the elements which contain one of these nodes \(z \in M_*\), will be marked.
(iii) Recursively, mark further elements \(T' \in T_*\) for refinement if there exists a marked element \(T \in T_*\) with \(T \cap T' \neq \emptyset\) and \(\hat{h}_{*,T'} > \hat{\kappa}_0 \hat{h}_{*,T}\).
(iv) Refine all marked elements \(T \in T_*\) by bisection and hence obtain \([T_+]\).

According to [1], the proposed recursion in step (iii) terminates and the generated partition \(T_+\) guarantees (M1) with \(\hat{\kappa}_{\text{max}} = 2\hat{\kappa}_0\). The following proposition shows that also the assumptions (M2)–(M3) are satisfied.

**Proposition 2.2** The proposed refinement strategy \(\text{ref}(.\) used in [24,25] satisfies Assumption 2.1, where \(\tilde{\kappa}_{\text{max}} = 2\hat{\kappa}_0\) and \(C_{\text{mesh}}\) depends only on the initial partition of the parameter domain, i.e., \(T_0\) transformed onto \([a, b]\).
Proof} For any partition $T_\bullet$ of $\Gamma$ and any subset of marked elements $S_\bullet \subseteq T_\bullet$, let $\overline{\text{ref}}(T_\bullet, S_\bullet)$ be the partition obtained from the recursive bisection in step (iii)–(iv) above. This local $h$-refinement procedure has been analyzed in [1]. According to [1, Theorem 2.3], the recursion is well-defined and guarantees $\overline{\kappa}_\bullet \leq 2\kappa_0$ for all $T_\bullet \in \overline{\text{ref}}(T_0)$.

To see (M2), [1, Theorem 2.3] guarantees the existence of some coarsest common refinement $T_\bullet \oplus T_+ \in \overline{\text{ref}}(T_\bullet) \cap \overline{\text{ref}}(T_+)$ such that

$$|T_\bullet \oplus T_+| \leq |T_\bullet| + |T_+| - |T_0|.$$  

The corresponding nodes just satisfy $N_\bullet \ominus N_+ = N_\bullet \cup N_+$. There exists a finite sequence of meshes $T_\bullet = \overline{T}_1, \overline{T}_2 = \overline{\text{ref}}(\overline{T}_1, S_1), \ldots, \overline{T}_\ell = \overline{\text{ref}}(\overline{T}_{\ell-1}, S_{\ell-1}) = T_\bullet \oplus T_+$ with suitable $S_j \subseteq T_j$ for $j = 1, \ldots, \ell - 1$. If we define $M_j \subseteq N_j$ as the set of all nodes in $S_j$, we see that the sequence $[T_\bullet] = [T_1], [T_2] = \overline{\text{ref}}([T_1], M_1), \ldots, [T_\ell] = \overline{\text{ref}}([T_{\ell-1}], M_{\ell-1})$ satisfies $T_j = \overline{T}_j$ for $j = 1, \ldots, \ell$. By repetitively marking one single node, we obtain from $[T_\ell]$ a mesh $[T_\bullet \oplus T_+]$ with nodes $N_\bullet \ominus N_+ = N_\bullet \cup N_+$ and $z = \max(\#_Z, \#_+ z)$, where $\#_Z$ resp. $\#_+$ denote the multiplicity in $K_\bullet$ resp. $K_+$ and, e.g., $\#_+ z := 0$ if $z \in N_\bullet \setminus N_+$. There obviously holds

$$|K_\bullet \ominus K_+| = \sum_{z \in N_\bullet \cup N_+} \#_z \leq |K_\bullet| + |K_+| - |K_0|.$$  

Moreover, $[T_\bullet \oplus T_+]$ is clearly a refinement of $[T_\bullet]$ as well.

Finally we consider (M3). As before we have $T_1 = \overline{\text{ref}}(T_0, S_0), \ldots, T_\ell = \overline{\text{ref}}(T_{\ell-1}, S_{\ell-1})$ for suitable $S_j \subseteq T_j$, $j = 0, \ldots, \ell - 1$. Note that there holds $|S_j| \leq 2|M_j|$. We denote $|\#_j| := |K_{j+1}| - |K_j| - (|N_{j+1}| - |N_j|)$ as the number of multiplicity increases during the $j$-th refinement. There holds

$$|K_{j+1}| - |K_j| = |T_{j+1}| - |T_j| + |\#_j|$$

and hence

$$|K_{\ell}| - |K_0| = |T_\ell| - |T_0| + \sum_{j=0}^{\ell-1} |\#_j|.$$  

The term $|T_\ell| - |T_0|$ can be estimated by $C \sum_{j=0}^{\ell-1} |S_j|$ with some constant $C > 0$ which depends only on the initial partition of the parameter domain, see [1, Theorem 2.3], and hence by $2C \sum_{j=0}^{\ell-1} |M_j|$. The estimate $|\#_j| \leq |M_j|$ concludes the proof with

$$C_{\text{mesh}} = 2C + 1.$$  

\[ \Box \]

2.7 B-splines and NURBS

Throughout this subsection, we consider knots $\tilde{\kappa} := (t_i)_{i \in \mathbb{Z}}$ on $\mathbb{R}$ with multiplicity $\# t_i$ which satisfy $t_{i-1} \leq t_i$ for $i \in \mathbb{Z}$ and $\lim_{i \to \pm \infty} t_i = \pm \infty$. Let $\tilde{N} := \{ t_i : i \in \mathbb{Z} \}$.
\( Z \) denote the corresponding set of nodes with \( \tilde{z}_{j-1} < \tilde{z}_j \) for \( j \in \mathbb{Z} \). For \( i \in \mathbb{Z} \), the \( i \)-th \( B \)-spline of degree \( p \) is defined inductively by (Fig. 2)

\[
B_{i,0} := \chi_{[t_{i-1},t_i)}, \\
B_{i,p} := \beta_{i-1,p} B_{i,p-1} + (1 - \beta_{i,p}) B_{i+1,p-1} \quad \text{for} \quad p \in \mathbb{N},
\]

where, for \( t \in \mathbb{R} \),

\[
\beta_{i,p}(t) := \begin{cases} 
\frac{t-t_i}{t_{i+p}-t_i} & \text{if } t_i \neq t_{i+p}, \\
0 & \text{if } t_i = t_{i+p}.
\end{cases}
\]

We also use the notations \( B_{i,p}^{\tilde{K}} := B_{i,p} \) and \( \beta_{i,p}^{\tilde{K}} := \beta_{i,p} \) to stress the dependence on the knots \( \tilde{K} \). The following lemma collects some basic properties of B-splines.

**Lemma 2.3** Let \( I = [a,b) \) be a finite interval and \( p \in \mathbb{N}_0 \). Then, the following assertions (i)–(vi) hold:

(i) The set \( \{ B_{i,p}|_I : i \in \mathbb{Z}, B_{i,p}|_I \neq 0 \} \) is a basis for the space of all right-continuous \( \tilde{N} \)-piecewise polynomials of degree lower or equal \( p \) on \( I \) which are, at each knot \( t_i \), \( p - \#t_i \) times continuously differentiable if \( p - \#t_i \geq 0 \).

Fig. 2 B-splines on the interval \([0, 1]\) corresponding to knot sequence \((\ldots, 0, 0, 0, 1/3, 1/3, 1/3, 2/3, 2/3, 1, 1, 1, \ldots)\)
(ii) For $i \in \mathbb{Z}$, $B_{i,p}$ vanishes outside the interval $[t_{i-1}, t_{i+p})$. It is positive on the open interval $(t_{i-1}, t_{i+p})$.

(iii) For $i \in \mathbb{Z}$, $B_{i,p}$ is completely determined by the $p + 2$ knots $t_{i-1}, \ldots, t_{i+p}$.

(iv) The B-splines of degree $p$ form a (locally finite) partition of unity, i.e.,

$$\sum_{i \in \mathbb{Z}} B_{i,p} = 1 \text{ on } \mathbb{R}. \quad (2.17)$$

**Proof** The proof of (i) is found in [14, Theorem 6], and (ii)–(iii) are proved in [14, Section 2]. (iv) is proved in [14, page 9–10]. \(\square\)

In addition to the knots $\check{\mathcal{K}} = (t_i)_{i \in \mathbb{Z}}$, we consider positive weights $\mathcal{W} := (w_i)_{i \in \mathbb{Z}}$ with $w_i > 0$. For $i \in \mathbb{Z}$ and $p \in \mathbb{N}_0$, we define the $i$-th NURBS by

$$R_{i,p} := \frac{w_i B_{i,p}}{\sum_{\ell \in \mathbb{Z}} w_\ell B_{\ell,p}}. \quad (2.18)$$

We also use the notation $\check{R}_{i,p}^{\mathcal{K}, \mathcal{W}} := R_{i,p}$. Note that the denominator is locally finite and positive.

For any $p \in \mathbb{N}_0$, we define the B-spline space

$$\mathcal{S}^p(\check{\mathcal{K}}) := \left\{ \sum_{i \in \mathbb{Z}} a_i B_{i,p} : a_i \in \mathbb{R} \right\}. \quad (2.19)$$

as well as the NURBS space

$$\mathcal{N}^p(\check{\mathcal{K}}, \mathcal{W}) := \left\{ \sum_{i \in \mathbb{Z}} a_i R_{i,p} : a_i \in \mathbb{R} \right\} = \frac{\mathcal{S}^p(\check{\mathcal{K}})}{\sum_{i \in \mathbb{Z}} w_\ell B_{\ell,p}^{\check{\mathcal{K}}, \mathcal{W}}}. \quad (2.20)$$

### 2.8 Ansatz spaces

Let $[T_0]$ be a given initial mesh with corresponding knots $\mathcal{K}_0$ such that $h_0 \leq |\Gamma|/4$ for closed $\Gamma = \partial \Omega$. We set $[\mathbb{T}] := x \in \mathbb{F}([T_0])$. Suppose that $\mathcal{W}_0 = (w_i)_{i=1}^{N-p}$ are given initial weights with $N = |\mathcal{K}_0|$ for closed $\Gamma = \partial \Omega$ resp. $N = |\mathcal{K}_0| - (p + 1)$ for open $\Gamma \subsetneq \partial \Omega$.

If $\Gamma = \partial \Omega$ is closed, we extend the transformed knot sequence $\check{\mathcal{K}}_0 = (t_i)_{i=1}^{N}$ arbitrarily to $(t_i)_{i \in \mathbb{Z}}$ with $t_{-p} = \cdots = t_0 = a, t_i \leq t_{i+1}, \lim_{i \to \pm \infty} t_i = \pm \infty$ and $\mathcal{W}_0 = (w_i)_{i \in \mathbb{Z}}$ with $w_i > 0$. For the extended sequences, we also write $\check{\mathcal{K}}_0$ and $\mathcal{W}_0$ and set

$$\mathcal{X}_0 := \mathcal{N}^p(\check{\mathcal{K}}_0, \mathcal{W}_0)|_{[a,b]} \circ \gamma|_{[a,b]}^{-1}. \quad (2.21)$$

If $\Gamma \not\subseteq \partial \Omega$ is open, we extend the sequences $\check{\mathcal{K}}_0 = (t_i)_{i=-p}^{N}$ and $\mathcal{W}_0$ arbitrarily to $(t_i)_{i \in \mathbb{Z}}$ with $t_i \leq t_{i+1}, \lim_{i \to \pm \infty} t_i = \pm \infty$ and $\mathcal{W}_0 = (w_i)_{i \in \mathbb{Z}}$ with $w_i > 0$. This
allows to define

\[ X_0 := \mathcal{N}^p (\tilde{K}_0, \mathcal{W}_0)|_{[a,b]} \circ \gamma^{-1}. \]  

(2.22)

Due to Lemma 2.3, this definition does not depend on how the sequences are extended.

Let \([T_*] \in [T]\) be a mesh with knots \(K_*\). Via knot insertion from \(K_0\) to \(K_*\), one obtains unique corresponding weights \(\mathcal{W}_*\). These are chosen such that the denominators of the NURBS functions do not change. In particular, this implies nestedness

\[ X_* \subseteq X_+ \quad \text{for all} \quad [T_*] \in [T], [T_] \in \mathcal{R}(T_*), \]  

(2.23)

where the spaces \(X_*\) resp. \(X_+\) are defined analogously to (2.21)–(2.22). Moreover, the weights are just convex combinations of \(\mathcal{W}_0\), wherefore

\[ w_{\text{min}} := \min(\mathcal{W}_0) \leq \min(\mathcal{W}_*) \leq \max(\mathcal{W}_*) \leq \max(\mathcal{W}_0) =: w_{\text{max}}. \]  

(2.24)

For further details, we refer to, e.g., [25, Section 4.2].

### 3 Adaptive algorithm and main results

For each mesh \([T_*] \in [T]\), define the node-based error estimator

\[ \mu_*^2 = \sum_{z \in N_*} \mu_*(z)^2, \]  

(3.1a)

where the refinement indicators read

\[ \mu_*(z)^2 := |\gamma^{-1}(\omega_*(z))| \| \partial \Gamma (f - V \Phi_*) \|_{L^2(\omega_*(z))}^2 \quad \text{for all} \quad z \in N_* \]  

(3.1b)

Here, we must additionally suppose \(f \in H^1(\Gamma)\) to ensure that \(\mu_*\) is well-defined. It has been proved in [24] that \(\mu_*\) is reliable, i.e.,

\[ \| \phi - \Phi_* \|_{H^{1/2}(\Gamma)} \leq C_{\text{rel}} \mu_*, \]  

(3.2)

where \(C_{\text{rel}} > 0\) depends only on \(p, w_{\text{min}}, w_{\text{max}}, \gamma,\) and \(\tilde{\kappa}_{\text{max}}\). We note that the weighted-residual error estimator in the form \(\mu_* \simeq \| h_*^{1/2} \partial \Gamma (f - V \Phi_*) \|_{L^2(\Gamma)}\) goes back to the works [6,13], where reliability (3.2) is proved for standard 2D BEM with piecewise constants on polyhedral geometries, while the corresponding result for 3D BEM is found in [12]. We consider the following adaptive algorithm which employs the Dörfler marking strategy (3.3) from [17] to single out nodes for refinement.

**Algorithm 3.1**

**Input:** Adaptivity parameter \(0 < \theta < 1\), \(C_{\text{mark}} \geq 1\), polynomial order \(p \in \mathbb{N}_0\), initial mesh \([T_0]\), initial weights \(\mathcal{W}_0\).

**Adaptive loop:** For each \(\ell = 0, 1, 2, \ldots\) iterate the following steps (i)–(iv):

(i) Compute discrete approximation \(\Phi_\ell \in X_\ell\) from Galerkin BEM.
(ii) Compute refinement indicators $\mu_\ell(z)$ for all nodes $z \in N_\ell$.

(iii) Determine an up to the multiplicative constant $C_{\text{mark}}$ minimal set of nodes $M_\ell \subseteq N_\ell$ such that

$$\theta \mu_\ell^2 \leq \sum_{z \in M_\ell} \mu_\ell(z)^2. \quad (3.3)$$

(iv) Generate refined mesh $[T_{\ell+1}] := x \in ([T_\ell], M_\ell)$.

**Output:** Approximate solutions $\Phi_\ell$ and error estimators $\mu_\ell$ for all $\ell \in \mathbb{N}_0$.

Our main result is that the proposed algorithm is linearly convergent, even with the optimal algebraic rate. For a precise statement of this assertion, let $[T_N] := \{[T_\star] \in [\mathcal{T}] : |K_\star| - |K_0| \leq N\}$ be the finite set of all refinements having at most $N$ knots more than $[T_0]$. Following [8], we introduce an estimator-based approximation class $A_s$ for $s > 0$: We write $\phi \in A_s$ if

$$\|\phi\|_{A_s} := \sup_{N \in \mathbb{N}_0} \left( (N + 1)^s \min_{[T] \in [T_N]} \mu_\star \right) < \infty. \quad (3.4)$$

In explicit terms, this just means that an algebraic convergence rate of $O(N^{-s})$ for the estimator is possible, if the optimal meshes are chosen. The following theorem is the main result of our work:

**Theorem 3.2** Let $f \in H^1(\Gamma)$, so that the weighted-residual error estimator $\mu_\ell$ from (3.1) is well-defined and that Algorithm 3.1 is driven by $\mu_\ell$. We suppose that the Assumption 2.1 on the mesh-refinement holds true. Then, for each $0 < \theta \leq 1$, there exist constants $0 < q_{\text{lin}} < 1$ and $C_{\text{lin}} > 0$ such that Algorithm 3.1 is linearly convergent in the sense of

$$\mu_{\ell+n} \leq C_{\text{lin}} q_{\text{lin}}^n \mu_\ell \quad \text{for all } \ell, n \in \mathbb{N}_0. \quad (3.5)$$

In particular, this implies convergence

$$C_{\text{rel}}^{-1} \|\phi - \Phi_\ell\|_{H^{-1/2}(\Gamma)} \leq \mu_\ell \leq C_{\text{lin}} q_{\text{lin}}^\ell \mu_0 \xrightarrow{\ell \to \infty} 0. \quad (3.6)$$

Moreover, there is a constant $0 < \theta_{\text{opt}} < 1$ such that for all $0 < \theta < \theta_{\text{opt}}$, there exists a constant $C_{\text{opt}} > 0$ such that, for all $s > 0$, it holds

$$\phi \in A_s \implies \mu_\ell \leq \frac{C_{\text{opt}}^{1+s}}{(1 - q_{\text{lin}}^{1/s})^s} \|\phi\|_{A_s} (|K_\ell| - |K_0|)^{-s} \quad \text{for all } \ell \in \mathbb{N}_0. \quad (3.7)$$

The constants $q_{\text{lin}}, C_{\text{lin}}$ depend only on $p, w_{\text{min}}, w_{\text{max}}, \gamma, \theta$, and $\tilde{\kappa}_{\text{max}}$ from (M1). The constant $\theta_{\text{opt}}$ depends only on $p, w_{\text{min}}, w_{\text{max}}, \gamma$, and (M1)–(M3), and $C_{\text{opt}}$ depends additionally on $\theta$. 

\( \odot \) Springer
Remark 3.3 The proof of Theorem 3.2 reveals that linear convergence (3.5) only requires (M1), while optimal rates (3.7) rely on (3.5) and (M2)–(M3). Provided that there exists a constant $C_{\text{son}} > 0$ such that $|K| \leq C_{\text{son}}|x(x([\mathcal{T}], \mathcal{M}_*))|$ for all $[\mathcal{T}] \in [\mathcal{T}]$ and $\mathcal{M}_* \subseteq \mathcal{N}_*$, also the converse implication in (3.7) holds true. The proof follows along the lines of [8, Proposition 4.15] and thus is left to the reader.

The proof of Theorem 3.2 is given in Sects. 4 and 5. The ideas essentially follow those of [8], where an axiomatic approach of adaptivity for abstract problems is found. We note, however, that [8] only considers $h$-refinement, while the present formulation of Algorithm 3.1 steers both, the $h$-refinement and the knot multiplicity increase.

If Algorithm 3.1 is steered by the Faermann estimator

$$
\eta_{\star}^2 = \sum_{z \in \mathcal{N}_*} \eta_{\star}(z)^2
$$

with the refinement indicators

$$
\eta_{\star}(z)^2 := |f - V \Phi_{\star}|^2_{H^{1/2}(\omega_{\star}(z))}
$$

for all $z \in \mathcal{N}_*$, instead of $\mu_{\star}$, we can prove at least plain convergence of the estimator to zero. In contrast to the weighted-residual estimator which requires additional regularity $f \in H^1(\Gamma)$, the Faermann estimator $\eta_{\star}$ allows a right-hand side $f \in H^{1/2}(\Gamma)$. Moreover, $\eta_{\star}$ estimator is efficient and reliable

$$
C^{-1}_{\text{eff}} \eta_{\star} \leq \|\phi - \Phi_{\star}\|_{\tilde{H}^{-1/2}(\Gamma)} \leq C_{\text{rel}} \eta_{\star},
$$

where $C_{\text{eff}} > 0$ depends only on $\Gamma$, while $C_{\text{rel}} > 0$ depends additionally on $p, \kappa_{\text{max}}, w_{\text{min}}, w_{\text{max}}$ and $\gamma$; see [25, Theorem 3.1 and 4.4]. This equivalence of error and estimator puts some interest on the following convergence theorem which is, however, weaker than the statement of Theorem 3.2.

**Theorem 3.4** Let $f \in H^{1/2}(\Gamma)$. We suppose that (M1) from Assumption 2.1 for the mesh-refinement holds. Then, for each $0 < \theta \leq 1$, Algorithm 3.1 steered by the Faermann estimator (3.8) is convergent in the sense of

$$
\eta_{\ell} \overset{\ell \to \infty}{\longrightarrow} 0.
$$

According to (3.9), this is equivalent to

$$
\|\phi - \Phi_{\ell}\|_{\tilde{H}^{-1/2}(\Gamma)} \overset{\ell \to \infty}{\longrightarrow} 0.
$$

Remark 3.5 The statements of Theorems 3.2 and 3.4 remain valid, if only adaptive $h$-refinement is used, i.e., if Algorithm 3.1 does not steer the knot multiplicity.
4 Proof of Theorem 3.2, linear convergence (3.5)

As an auxiliary result, we need an inverse-type estimate for NURBS with respect to the fractional $H^{-1/2}(Γ)$-norm. In the following, a result is stated and proved for the $H^{-σ}(Γ)$-norm, where $0 < σ < 1$. For piecewise polynomials, an analogous result is already found in [30, Theorem 3.6] resp. [29, Theorem 3.9]. Our proof is inspired by [15, Section 4.3], where a similar result is found for piecewise constant functions as well as for piecewise affine and globally continuous functions in 1D. For integer-order Sobolev norms, inverse estimates for NURBS are found in [3, Section 4], and (4.2) is proved in [2, Theorem 3.1] for piecewise polynomials.

**Proposition 4.1** Let $[T⋆] ∈ [T]$ and $0 < σ < 1$. Then, there is a constant $C_{inv} > 0$ such that

$$∥h^σ⋆Ψ⋆∥_{L^2(Γ)} ≤ C_{inv}∥Ψ⋆∥_{H^{-σ}(Γ)}$$ for all $Ψ⋆ ∈ X⋆$. (4.1)

For $σ = 1/2$, it holds

$$∥h^{1/2}(*\partialΓ(VΨ⋆))∥_{L^2(Γ)} + ∥h^{1/2}Ψ⋆∥_{L^2(Γ)} ≤ C_{inv}∥Ψ⋆∥_{H^{-1/2}(Γ)}$$ for all $Ψ⋆ ∈ X⋆$. (4.2)

The constant $C_{inv}$ only depends on $κ_{max}$, $p$, $w_{min}$, $w_{max}$, $γ$, and $σ$.

**Proof** The proof is done in four steps. First, we show that $∥h^σψ∥_{L^2(Γ)} ≤ C∥ψ∥_{H^{-σ}(Γ)}$ holds for all $ψ ∈ L^2(Γ)$ which satisfy a certain assumption. In the second step, we prove an auxiliary result for polynomials which is needed in the third one, where we show that all $ψ ∈ X⋆$ satisfy the mentioned assumption. In the last step, we apply a recent result of [2], which then concludes the proof.

**Step 1** Let $X ⊂ L^2(Γ)$ satisfy the following assumption: There exists a constant $q ∈ (0, 1)$ such that for all $T ∈ T⋆$ and all $ψ ∈ X$ there exists some connected subset $Δ(T, ψ) ⊆ T$ of length $|Δ(T, ψ)| ≥ q|T|$ such that $ψ$ does not change its sign on $Δ(T, ψ)$ and

$$\min_{x ∈ Δ(T, ψ)} |ψ(x)| ≥ q \max_{x ∈ T} |ψ(x)|. (4.3)$$

Then, there exists a constant $C > 0$ which depends only on $q$ and $κ⋆$, such that

$$∥h^σψ∥_{L^2(Γ)} ≤ C∥ψ∥_{H^{-σ}(Γ)}$$ for all $ψ ∈ X$. (4.4)

For a compact nonempty interval $[c, d] = I ⊆ [a, b]$, we define the bubble function

$$P_I(t) := \begin{cases} \left(\frac{t-c}{d-c}, \frac{d-t}{d-c}\right)^2 & \text{if } t ∈ I, \\ 0 & \text{if } t ∈ [a, b] \setminus I. \end{cases}$$
It obviously satisfies $0 \leq P_I \leq 1$ and $\text{supp} P_I = I$. A standard scaling argument proves

$$C_1 |I| \leq \| P_I \|_{L^2(I)}^2 \leq \| P_I \|_{L^1(I)} \leq C_2 |I| \quad (4.4)$$

and

$$|I|^2 \| P' \|_{L^2(I)}^2 \leq C_3 \| P_I \|_{L^2(I)}^2 \quad (4.5)$$

with generic constants $C_1, C_2, C_3 > 0$ which do not depend on $I$. For each $T \in \mathcal{T}_*$, let $I(T, \psi)$ be some interval with $\gamma(I(T, \psi)) = \Delta(T, \psi)$. With the arclength parametrization $\gamma_L$, we define, for all $T \in \mathcal{T}_*$, the functions $P_{\Delta(T, \psi)} := P_I(T, \psi) \circ \gamma_L$ and the coefficients

$$c_T := \text{sgn}(\psi|_{\Delta(T, \psi)}) h^{2\sigma}_{*,T} \min_{x \in \Delta(T, \psi)} |\psi(x)|. \quad (4.6)$$

Note that (4.4) and (4.5) hold for $P_{\Delta(T, \psi)}$ with $I$ simply replaced by $\Delta(T, \psi)$ and with $(\cdot)'$ replaced by the arclength derivative $\partial_\Gamma$. By definition of the dual norm, it holds

$$\| \psi \|_{\bar{H}^{-\sigma}(\Gamma)} \geq \frac{|\langle \psi ; \chi \rangle|}{\| \chi \|_{H^0(\Gamma)}} \quad \text{with, e.g., } \chi := \sum_{T \in \mathcal{T}_*} c_T P_{\Delta(T, \psi)} \in H^1(\Gamma) \subset H^\sigma(\Gamma). \quad (4.7)$$

First, we estimate the numerator in (4.7):

$$|\langle \psi ; \chi \rangle| = \left| \sum_{T \in \mathcal{T}_*} \int_T \psi(x) c_T P_{\Delta(T, \psi)}(x) \, dx \right|$$

$$\overset{(4.6)}{=} \sum_{T \in \mathcal{T}_*} h^{2\sigma}_{*,T} \min_{x \in \Delta(T, \psi)} |\psi(x)|^2 \| P_{\Delta(T, \psi)} \|_{L^1(\Delta(T, \psi))}$$

$$\overset{(4.3)}{\geq} q^2 \sum_{T \in \mathcal{T}_*} h^{2\sigma}_{*,T} \max_{x \in T} |\psi(x)|^2 \| P_{\Delta(T, \psi)} \|_{L^1(\Delta(T, \psi))}$$

$$\overset{(4.4)}{\geq} C_1 q^3 \sum_{T \in \mathcal{T}_*} h^{2\sigma}_{*,T} \| \psi \|_{L^2(T)}^2$$

$$= C_1 q^3 \| h^\sigma_\ast \psi \|_{L^2(\Gamma)}^2.$$

It remains to estimate the denominator in (4.7): We first note that it holds $|u|^{2\sigma}_{H^\sigma(\Gamma)} \lesssim |I|^{1-\sigma} \| u' \|_{L^2(I)}$ for any interval $I \subset \mathbb{R}$ of finite length and $u \in H^1(I)$. This is already stated in [7, Lemma 7.4]. However, a detailed proof is given only for $1/2 < \sigma < 1$. For $0 < \sigma \leq 1/2$ this inequality can be shown exactly as in the proof of [24, Lemma 4.5],
where only $\sigma = 1/2$ is considered. This, together with (2.8), implies for any connected $\omega \subseteq \Gamma$ with $|\omega| \leq \frac{3}{4}|\Gamma|$ that

$$|u|_{H^\sigma(\omega)} \lesssim |\omega|^{1-\sigma} \|\partial_{\Gamma} u\|_{L^2(\omega)} \quad \text{for all } u \in H^1(\Gamma).$$

(4.8)

The hidden constant in (4.8) depends only on $\sigma$ and $\Gamma$. Equation (4.8) is applicable for any node patch $\omega_\ast(z)$ since we assumed in Sect. 2.8 that $h_0 \leq |\Gamma|/4$ if $\Gamma = \partial \Omega$. With [18, Lemma 2.3], we hence see

$$|\chi|_{H^\sigma(\Gamma)}^2 \lesssim \|h^{-\sigma}_\ast \chi\|_{L^2(\Gamma)}^2 + \sum_{z \in N_\ast} |\chi|_{H^\sigma(\omega_z)}^2$$

(4.8)

$$\lesssim \|h^{-\sigma}_\ast \chi\|_{L^2(\Gamma)}^2 + \sum_{z \in N_\ast} \|h^{1-\sigma}_\ast \partial_{\Gamma} \chi\|_{L^2(\omega_z)}^2$$

$$\simeq \|h^{-\sigma}_\ast \chi\|_{L^2(\Gamma)}^2 + \sum_{T \in T_\ast} \|h^{1-\sigma}_\ast \partial_{\Gamma} \chi\|_{L^2(\Delta(T,\psi))}^2$$

$$= \|h^{-\sigma}_\ast \chi\|_{L^2(\Gamma)}^2 + \sum_{T \in T_\ast} h^{2-2\sigma}_\ast c_T^2 \|\partial_{\Gamma} P_{\Delta(T,\psi)}\|_{L^2(\Delta(T,\psi))}^2$$

(4.5)

$$\lesssim \|h^{-\sigma}_\ast \chi\|_{L^2(\Gamma)}^2 \quad \text{for all } \chi \in H^\sigma(\Gamma).$$

This yields

$$\|\chi\|_{H^\sigma(\Gamma)}^2 = \|\chi\|_{L^2(\Gamma)}^2 + |\chi|_{H^\sigma(\Gamma)}^2 \lesssim \|h^{-\sigma}_\ast \chi\|_{L^2(\Gamma)}^2,$$

where the hidden constant depends only on $\kappa_{\max}, \sigma$, and $\gamma$. With

$$\|h^{-\sigma}_\ast \chi\|_{L^2(\Gamma)}^2 = \sum_{T \in T_\ast} h^{2\sigma}_\ast c_T^2 \|\partial_{\Gamma} P_{\Delta(T,\psi)}\|_{L^2(\Delta(T,\psi))}^2 \leq C_2 \sum_{T \in T_\ast} h^{2\sigma}_\ast c_T^2 \|\partial_{\Gamma} P_{\Delta(T,\psi)}\|_{L^2(\Delta(T,\psi))}$$

(4.6)

$$\leq C_2 \sum_{T \in T_\ast} h^{2\sigma}_\ast \min_{x \in \Delta(T,\psi)} |\psi(x)|^2 \|\partial_{\Gamma} P_{\Delta(T,\psi)}\|_{L^2(\Delta(T,\psi))}$$

$$\leq C_2 \|h^{\sigma}_\ast \psi\|_{L^2(\Gamma)}^2$$

we finish the first step.

**Step 2** For some fixed polynomial degree $p \in \mathbb{N}_0$, there exists a constant $q_1 \in (0, 1)$ such that for all polynomials $F$ of degree $p$ on $[0, 1]$ there exists some interval $I \subseteq [0, 1]$ of length $|I| \geq q_1$ with

$$\min_{t \in I} |F(t)| \geq q_1 \max_{t \in [0,1]} |F(t)|.$$  

(4.9)
Instead of considering general polynomials $\mathcal{P}^p([0, 1])$ of degree $p$, it is sufficient to consider the following subset

$$
\mathcal{M} := \{ F \in \mathcal{P}^p([0, 1]) : \| F \|_\infty = 1 \}.
$$

Note that $\mathcal{M}$ is a compact subset of $L^\infty([0, 1])$ and that differentiation $(\cdot)'$ is a continuous mapping on $\mathcal{M}$ due to finite dimension. This especially implies boundedness $\text{sup}_{F \in \mathcal{M}} \| F \|_\infty \leq C_4 < \infty$. We may assume $C_4 > 2$. For given $F \in \mathcal{M}$, we define the interval $I$ as follows: Without loss of generality, we assume that the maximum of $|F|$ is attained at some $t_1 \in [0, 1/2]$ and that $F(t_1) = 1$. We set $t_3 := t_1 + C_4^{-1} \in (t_1, 1]$ and $t_2 := t_1 + C_4^{-1}/2 \in (t_1, 3/4]$ and $I := [t_1, t_2]$. Then, $|I| = 1/(2C_4)$ and for all $t \in I$ it holds

$$
1/2 \leq C_4(t_3 - t) = F(t_1) + C_4(t_1 - t) \leq F(t_1) + \| F' \|_\infty (t_1 - t) \leq F(t) = |F(t)|.
$$

Altogether, we thus have

$$
q_1 := 1/(2C_4) \leq 1/2 \leq \min_{t \in I} |F(t)| \quad \text{and} \quad |I| = q_1
$$

and conclude this step.

**Step 3** We show that $\mathcal{X}_\ast$ satisfies the assumption of Step 1 and hence conclude $\| h_{\ast}^p \Psi_\ast \|_{L^2(\Gamma)} \lesssim \| \Psi_\ast \|_{\tilde{H}^{-1/2}(\Gamma)}$ for all $\Psi_\ast \in \mathcal{X}_\ast$: Let $\tilde{T} \subset [a, b]$ be the interval with $\gamma(\tilde{T}) = T$ and $\tilde{\Psi} := \Psi \circ \gamma|_{\tilde{T}}$. Since $|I| \simeq |\gamma(I)|$ for any interval $I \subseteq [a, b]$, where the hidden constants depend only on $\gamma$, we just have to find a uniform constant $q_2 \in (0, 1)$ and some interval $I \subseteq \tilde{T}$ of length $|I| \geq q_2 |\tilde{T}|$ with

$$
\min_{t \in I} |\tilde{\Psi}(t)| \geq q_2 \max_{x \in \tilde{T}} |\tilde{\Psi}(t)|.
$$

The function $\tilde{\Psi}$ has the form $F/w$ with a polynomial $F$ of degree $p$ and the weight function $w$, which is also a polynomial of degree $p$ and which satisfies $w_{\min} \leq w \leq w_{\max}$. Hence, (4.10) is especially satisfied if

$$
\min_{t \in I} |F(t)| \geq q_1 \frac{w_{\max}}{w_{\min}} \max_{x \in \tilde{T}} |\tilde{\Psi}(t)|.
$$

After scaling to the interval $[0, 1]$, we can apply Step 2 and conclude this step. Altogether, this proves (4.1).

**Step 4** According to [2], it holds $\| h_{\ast}^{1/2} \partial_\Gamma (V \Psi) \|_{L^2(\Gamma)} \lesssim \| h_{\ast}^{1/2} \Psi \|_{L^2(\Gamma)} + \| \Psi \|_{\tilde{H}^{-1/2}(\Gamma)}$ for all $\Psi \in L^2(\Gamma)$, where the hidden constant depends only on $\Gamma$, $\gamma$, and $\tilde{k}_{\max}$. Together with Step 3, this shows (4.2).

The proof of linear convergence (3.5) will be done with the help of some auxiliary (and purely theoretical) error estimator $\hat{\eta}_\ast$. The latter relies on the following definition of an equivalent mesh-size function which respects the multiplicity of the knots.
Proposition 4.2 Assumption 2.1 (M1) implies the existence of a modified mesh-size function $\tilde{h} : [T] \to L^\infty (\Gamma)$ with the following properties: There exists a constant $C_{\text{wl}} > 0$ and $0 < q_{\text{ctr}} < 1$ which depend only on $\kappa_{\text{max}}, p$ and $\gamma$ such that for all $[T_*] \in [T]$ and all refinements $[T_+] \in x \in \mathcal{E}([T_*])$, the corresponding mesh-sizes $\tilde{h}_* := \tilde{h}([T_*])$ and $\tilde{h}_+ := \tilde{h}([T_+])$ satisfy equivalence

$$C_{\text{wl}}^{-1} \tilde{h}_* \leq \tilde{h}_+ \leq C_{\text{wl}} \tilde{h}_*, \quad (4.12)$$

as well as contraction on the patch of refined elements

$$\tilde{h}_+|_{\omega_+([T_+]|\{T_*})} \leq q_{\text{ctr}} \tilde{h}_*|_{\omega_+([T_+]|\{T_*}). \quad (4.13)$$

Note that $\omega_+([T_+]|\{T_*}) = \omega_*(\{T_*\}|\{T_*})$, which follows from $\bigcup([T_+]|\{T_*}) = \bigcup((\{T_*\}|\{T_*})$ and the fact that the application of $\omega_+$ resp. $\omega_*$ only adds elements of $T_+ \cap T_*$. First, suppose $x \notin \omega_+([T_+]|\{T_*}) \cup \mathcal{N}_+$, i.e., neither the element $[T] \in \{T_*\}$ containing $x$ nor its neighbors result from $h$-refinement or from multiplicity increase. Then, $\tilde{h}_+(x) = \tilde{h}_*(x)$. Second, suppose $x \in \omega_+([T_+]|\{T_*}) \cap \mathcal{N}_+$, i.e., the element $[T'] \in [T_+]$ containing $x$ or one of its neighbors result from $h$-refinement and/or multiplicity increase. If only multiplicity increase took place, we get

$$q_1 \sum_{z \in \mathcal{N}_+ \cap \omega_+(T')} \#z \leq q_1 \cdot \sum_{z \in \mathcal{N}_+ \cap \omega_+(T)} \#z.$$

where $0 < q_1 < 1$ is fixed later. Clearly, $\tilde{h}_* \simeq \tilde{h}_+$, where the hidden equivalence constants depend only on $\kappa_{\text{max}}, p,$ and $q_1$. Let $x \in \Gamma$. First, suppose $x \notin \omega_+([T_+]|\{T_*}) \cup \mathcal{N}_+$, i.e., neither the element $[T] \in \{T_*\}$ containing $x$ nor its neighbors result from $h$-refinement or from multiplicity increase. Then, $\tilde{h}_+(x) = \tilde{h}_*(x)$. Second, suppose $x \in \omega_+([T_+]|\{T_*}) \cap \mathcal{N}_+$, i.e., the element $[T'] \in [T_+]$ containing $x$ or one of its neighbors result from $h$-refinement and/or multiplicity increase. If only multiplicity increase took place, we get

$$q_1 \sum_{z \in \mathcal{N}_+ \cap \omega_+(T')} \#z \leq q_1 \cdot \sum_{z \in \mathcal{N}_+ \cap \omega_+(T)} \#z.$$

In the other case, consider the father $[T] \in [T_*]$ of $[T']$, i.e., $T' \subseteq T$. Note that

$$|\gamma^{-1}(\omega_+(T'))| \leq q_2 |\gamma^{-1}(\omega_+(T))|$$

with a constant $0 < q_2 < 1$ which depends only on $\kappa_{\text{max}}$. Choose $0 < q_1 < 1$ sufficiently large such that

$$q_2/q_1^{4p} < 1.$$

This choice yields $\tilde{h}_+(x) \leq (q_2/q_1^{4p}) \cdot \tilde{h}_*(x)$, since $\mathcal{N}_+ \cap \omega_+(T)$ contains at most 4 nodes. Therefore, we conclude the proof with $q_{\text{ctr}} := \max(q_1, q_2/q_1^{4p})$. \qed
Remark 4.3  Note that the construction of $\tilde{h}_*$ in Proposition 4.2 even ensures contraction $\tilde{h}_*|_{\omega_1+}(T) \leq q_{\text{wrt}} \tilde{h}_*|_{\omega_1+}(T)$ if $[T] \in [\mathcal{T}_*] \setminus [\mathcal{T}_*]$ is obtained by $h$-refinement, while the multiplicity of all nodes $z \in \mathcal{N}_+ \cap \omega_1+(T)$ is arbitrarily chosen $\# z \in \{1, \ldots, p+1\}$. In explicit terms, this allows for instance to set the multiplicity of all nodes $z \in \mathcal{N}_+ \cap \omega_1+(T)$ to $\# z := 1$, if $T$ is obtained by $h$-refinement. □

For any $[\mathcal{T}_*] \in [\mathcal{T}]$, we define the auxiliary estimator

$$\tilde{\rho}_*^2 := \sum_{T \in \mathcal{T}} \tilde{\rho}_*^2(T) \quad \text{with} \quad \tilde{\rho}_*^2(T) := \|\tilde{h}_*^{1/2} \partial_T (f - V \Phi_*)\|_{L^2(T)}^2$$

(4.15)

which employs the novel mesh-size function $\tilde{h}_*$ from Proposition 4.2. Obviously the estimators $\mu_*$ and $\tilde{\rho}_*$ are locally equivalent

$$\tilde{\rho}_*^2(T) \lesssim \mu_*^2(z) \lesssim \sum_{T' \in \mathcal{T}_*} \tilde{\rho}_*^2(T') \quad \text{for all } z \in \mathcal{N}_* \text{ and } T \in \mathcal{T}_* \text{ with } z \in T, \tag{4.16}$$

where the hidden constants depend only on $\tilde{k}_{\text{max}}$, $p$, and $\gamma$. The proof of the following lemma is inspired by [26, Proposition 3.2] resp. [8, Lemma 8.8], where only $h$-refinement is considered.

**Lemma 4.4** (Estimator reduction of $\tilde{\rho}$) Algorithm 3.1 guarantees

$$\tilde{\rho}_{\ell+1}^2 \leq q_{\text{est}} \tilde{\rho}_{\ell}^2 + C_{\text{est}} \|\Phi_{\ell+1} - \Phi_\ell\|_{H^{-1/2}(\Gamma)}^2 \quad \text{for all } \ell \geq 0. \tag{4.17}$$

The constants $0 < q_{\text{est}} < 1$ and $C_{\text{est}} > 0$ depend only on $\tilde{k}_{\text{max}}$, $p$, $w_{\text{min}}$, $w_{\text{max}}$, $\gamma$, and $\theta$.

**Proof** The proof is done in several steps.

**Step 1** With the inverse estimate (4.2), there holds the following stability property for any measurable $\Gamma_0 \subseteq \Gamma$

$$\left| \|\tilde{h}_{\ell+1}^{1/2} \partial_T (f - V \Phi_{\ell+1})\|_{L^2(\Gamma_0)} - \|\tilde{h}_{\ell+1}^{1/2} \partial_T (f - V \Phi_\ell)\|_{L^2(\Gamma_0)} \right| \leq \|\tilde{h}_{\ell+1}^{1/2} \partial_T V(\Phi_{\ell+1} - \Phi_\ell)\|_{L^2(\Gamma_0)} \leq C\|\Phi_{\ell+1} - \Phi_\ell\|_{H^{-1/2}(\Gamma)},$$

with a constant $C > 0$ which depends only on $C_{w_t}$, $C_{\text{inv}}$, and $\gamma$.

**Step 2** With Proposition 4.2, we split the estimator into a contracting and into a noncontracting part

$$\tilde{\rho}_{\ell+1}^2 = \|\tilde{h}_{\ell+1}^{1/2} \partial_T (f - V \Phi_{\ell+1})\|_{L^2(\omega_{\ell+1}([\mathcal{T}_{\ell+1}] \setminus [\mathcal{T}_\ell]))}^2 + \|\tilde{h}_{\ell+1}^{1/2} \partial_T (f - V \Phi_{\ell+1})\|_{L^2(\Gamma \setminus \omega_{\ell+1}([\mathcal{T}_{\ell+1}] \setminus [\mathcal{T}_\ell]))}^2$$

\(\odot\) Springer
Step 1, the Young inequality, and Proposition 4.2 show, for arbitrary \( \delta > 0 \), that

\[
\| \tilde{h}_{\ell+1}^{1/2} \partial_f (f - V \Phi_{\ell+1}) \|_{L^2(\omega_{\ell+1}(|T_{\ell+1}|\setminus|T_{\ell}|))}^2 \\
\leq (1 + \delta)\| \tilde{h}_{\ell}^{1/2} \partial_f (f - V \Phi_{\ell}) \|_{L^2(\omega_{\ell}(|T_{\ell}|\setminus|T_{\ell+1}|))}^2 \\
+ (1 + \delta^{-1})C^2 \| \Phi_{\ell+1} - \Phi_{\ell} \|_{H^{-1/2}(\Gamma)}^2 \\
\leq (1 + \delta)q_{\text{ctr}}\| \tilde{h}_{\ell}^{1/2} \partial_f (f - V \Phi_{\ell}) \|_{L^2(\omega_{\ell}(|T_{\ell}|\setminus|T_{\ell+1}|))}^2 \\
+ (1 + \delta^{-1})C^2 \| \Phi_{\ell+1} - \Phi_{\ell} \|_{H^{-1/2}(\Gamma)}^2.
\]

Analogously, we get

\[
\| \tilde{h}_{\ell+1}^{1/2} \partial_f (f - V \Phi_{\ell+1}) \|_{L^2(\Gamma \setminus \omega_{\ell+1}(|T_{\ell+1}|\setminus|T_{\ell}|))}^2 \\
\leq (1 + \delta)\| \tilde{h}_{\ell}^{1/2} \partial_f (f - V \Phi_{\ell}) \|_{L^2(\Gamma \setminus \omega_{\ell}(|T_{\ell}|\setminus|T_{\ell+1}|))}^2 \\
+ (1 + \delta^{-1})C^2 \| \Phi_{\ell+1} - \Phi_{\ell} \|_{H^{-1/2}(\Gamma)}^2.
\]

Combining these estimates, we end up with

\[
\tilde{\rho}_{\ell+1}^2 \\
= (1 + \delta)\tilde{\rho}_{\ell}^2 - (1 + \delta)(1 - q_{\text{ctr}})\| \tilde{h}_{\ell}^{1/2} \partial_f (f - V \Phi_{\ell}) \|_{L^2(\omega_{\ell}(|T_{\ell}|\setminus|T_{\ell+1}|))}^2 \\
+ 2(1 + \delta^{-1})C^2 \| \Phi_{\ell+1} - \Phi_{\ell} \|_{H^{-1/2}(\Gamma)}^2 .
\]

\[\tag{4.18}
\]

**Step 3** Local equivalence (4.16) and the Dörfler marking (3.3) for \( \mu_{\ell} \) imply

\[
\theta \tilde{\rho}_{\ell}^2 \simeq \theta \mu_{\ell}^2 \leq \sum_{z \in \mathcal{M}_{\ell}} \mu_{\ell}(z)^2 \simeq \sum_{T \in T_{\ell}} \tilde{\rho}_{\ell}(T)^2 ,
\]

where the hidden constants depend only on \( \kappa_{\text{max}} \), \( p \), and \( \gamma \). Hence, \( \tilde{\rho}_{\ell} \) satisfies some Dörfler marking with a certain parameter \( 0 < \theta < 1 \). With \( \mathcal{M}_{\ell} \subseteq \bigcup (|T_{\ell}| \setminus |T_{\ell+1}|) \), (4.18) hence becomes

\[
\tilde{\rho}_{\ell+1}^2 \leq (1 + \delta) - (1 + \delta)(1 - q_{\text{ctr}})\tilde{\theta}) \tilde{\rho}_{\ell}^2 + 2(1 + \delta^{-1})C^2 \| \Phi_{\ell+1} - \Phi_{\ell} \|_{H^{-1/2}(\Gamma)}^2.
\]

By choosing \( \delta \) sufficiently small, we prove (4.17) with \( C_{\text{est}} := 2(1 + \delta^{-1})C^2 \) and \( q_{\text{est}} := (1 + \delta)(1 - (1 - q_{\text{ctr}})\tilde{\theta}) < 1 \).

**Proof of linear convergence (3.5)** Due to the properties of the weakly-singular integral operator \( V \), the bilinear form \( A(\phi, \psi) := \langle V \phi; \psi \rangle_{\Gamma} \) defines even a scalar product, and the induced norm \( \| \psi \|_{V} := A(\psi, \psi)^{1/2} \) is an equivalent norm on \( H^{-1/2}(\Gamma) \). According to nestedness of the ansatz spaces \( X_{\ell} \subseteq X_{\ell+1} \), the Galerkin orthogonality implies the Pythagoras theorem

\[
\| \phi - \Phi_{\ell+1} \|_{V}^2 + \| \Phi_{\ell+1} - \Phi_{\ell} \|_{V}^2 = \| \phi - \Phi_{\ell} \|_{V}^2 \quad \text{for all } \ell \in \mathbb{N}_0.
\]
Together with the estimator reduction (4.17) and reliability (3.2)
\[
\|\phi - \Phi_\ell\|_V \simeq \|\phi - \Phi_\ell\|_{\tilde{H}^{-1/2}(\Gamma)} \lesssim \mu_\ell \simeq \tilde{\rho}_\ell,
\]
this implies the existence of \(0 < \kappa, \lambda < 1\), which depend only on \(C_{\text{rel}}, C_{\text{est}}\) and \(q_{\text{est}}\), such that \(\Delta_\star := \|\phi - \Phi_\star\|_V^2 + \lambda \tilde{\rho}_\star^2 \simeq \tilde{\rho}_\star^2\) satisfies
\[
\Delta_{\ell+1} \leq \kappa \Delta_\ell \quad \text{for all } \ell \in \mathbb{N}_0;
\]
see, e.g., [26, Theorem 4.1], while the original idea goes back to [10]. From this, we infer
\[
\mu_\ell^2 + \nu \simeq \tilde{\rho}_\ell^2 + \nu \lesssim \Delta_\ell + \nu \leq \kappa \nu \tilde{\rho}_\ell^2 \simeq \kappa \nu \mu_\ell^2 \quad \text{for all } \ell, \nu \in \mathbb{N}_0
\]
and hence conclude the proof.

\[\square\]

5 Proof of Theorem 3.2, optimal convergence (3.7)

As in the previous section, we define an auxiliary error estimator. For each \([T_\star] \in \{\mathbb{T}\}\), let
\[
\rho_\star^2 := \sum_{T \in T} \rho_\star(T)^2 \quad \text{with} \quad \rho_\star(T)^2 := \|\tilde{h}_\star^{1/2} \partial_T (f - V \Phi_\star)^2\|_{L^2(T)}.
\] (5.1)

Note that the estimators \(\mu_\star\) and \(\rho_\star\) are again locally equivalent
\[
\rho_\star(T) \leq \mu_\star(z) \lesssim \sum_{T' \in T} \rho_\star(T') \quad \text{for all } z \in N_\star \text{ and } T \in T_\star \text{ with } z \in T,
\] (5.2)

where the hidden constant depends only on \(\kappa_{\text{max}}\). Analogous versions of the next two lemmas are already proved in [26, Proposition 4.2 and 4.3] for \(h\)-refinement and piecewise constants; see also [8, Proposition 5.7] for discontinuous piecewise polynomials and \(h\)-refinement. The proof for Lemma 5.1 is essentially based on Proposition 4.1. The proof of Lemma 5.2 requires the construction of a Scott–Zhang type operator (5.9) which is not necessary in [8,26], since both works consider discontinuous piecewise polynomials.

Lemma 5.1 (Stability of \(\rho\)) Let \([T_\star] \in \{\mathbb{T}\} \text{ and } [T_+] \in \mathcal{K}(T_\star). \text{ For } \mathcal{S} \subseteq T_\star \cap T_+ \text{ there holds}
\[
\left\| \left( \sum_{T \in \mathcal{S}} \rho_+(T)^2 \right)^{1/2} - \left( \sum_{T \in \mathcal{S}} \rho_\star(T)^2 \right)^{1/2} \right\| \leq C_{\text{stab}} \|\Phi_+ - \Phi_\star\|_{\tilde{H}^{-1/2}(\Gamma)},
\] (5.3)

where \(C_{\text{stab}} > 0\) depends only on the parametrization \(\gamma\) and the constant \(C_{\text{inv}}\) of Proposition 4.1.
Proof

For all subsets $\Gamma_0 \subseteq \Gamma$, it holds

$$
\left\| \tilde{h}^{1/2} \partial_{\Gamma} (f - V \Phi_+) \right\|_{L^2(\Gamma_0)} - \left\| \tilde{h}^{1/2} \partial_{\Gamma} (f - V \Phi_*) \right\|_{L^2(\Gamma_0)} \\
\leq \left\| \tilde{h}^{1/2} \partial_{\Gamma} V (\Phi_+ - \Phi_*) \right\|_{L^2(\Gamma_0)} \\
\lesssim \left\| \tilde{h}^{1/2} \partial_{\Gamma} V (\Phi_+ - \Phi_*) \right\|_{L^2(\Gamma_0)} \leq C_{\text{inv}} \left\| \Phi_+ - \Phi_* \right\|_{H^{-1/2}(\Gamma)}.
$$

The choice $\Gamma_0 = \bigcup S$ shows stability

$$
\left( \sum_{T \in S} \rho_+(T)^2 \right)^{1/2} - \left( \sum_{T \in S} \rho_*(T)^2 \right)^{1/2} \leq C_{\text{inv}} \left\| \Phi_+ - \Phi_* \right\|_{H^{-1/2}(\Gamma)},
$$

and we conclude the proof. \qed

Lemma 5.2 (Discrete reliability of $\rho$) There exist constants $C_{\text{rel}}, C_{\text{ref}} > 0$, which depend only on $K_{\text{max}}, p, w_{\text{min}}, w_{\text{max}}$, and $\gamma$, such that for all refinements $[T_+] \in \mathcal{R}(\mathcal{H})$ of $[T_*] \in \mathcal{T}_*$ there exists a subset $\mathcal{R}_*(T_+) \subseteq \mathcal{T}_*$ with

$$
\| \Phi_+ - \Phi_* \|^2_{H^{-1/2}(\Gamma)} \leq C_{\text{rel}} \sum_{T \in \mathcal{R}_*(T_+)} \rho_*(T)^2
$$

as well as

$$
\bigcup ([T_*] \setminus [T_+]) \subseteq \bigcup \mathcal{R}_*(T_+) \text{ and } |\mathcal{R}_*(T_+)| \leq C_{\text{ref}} |[T_*] \setminus [T_+]|.
$$

For the proof of Lemma 5.2, we need to introduce a Scott–Zhang type operator. Let $[T_*] \in \mathcal{T}$ and $\{ R_{i,p}|_{(a,b)} : i = 1 - p, \ldots, N - p \} \circ \gamma|_{[a,b]}$ be the basis of NURBS of $\mathcal{X}_*$, where “$|$” stands for “$|$” if $\Gamma = \partial \Omega$ is closed and for “$|$” if $\Gamma \cap \partial \Omega$ is open. Here, $N$ denotes the number of transformed knots $\tilde{K}_*$ in $(a, b)$. With the corresponding B-splines there holds $R_{i,p} = w_i B_{i,p}/w$, where $w = \sum_{t \in \mathbb{Z}} w_t B_{t,p}$ is the fixed denominator satisfying $w_{\text{min}} \leq w \leq w_{\text{max}}$; see Sect. 2.8. In [4, Section 2.1.5], it is shown that, for $i \in \{1 - p, \ldots, N - p\}$, there exist dual basis functions $B_{i,p}^* \in L^2(\text{supp} B_{i,p})$ with

$$
\int_{\text{supp} B_{i,p}} B_{i,p}^* (t) B_{j,p} (t) \, dt = \delta_{ij} = \begin{cases} 1 & \text{if } i = j, \\ 0 & \text{else,} \end{cases}
$$

and

$$
\| B_{i,p}^* \|_{L^2(\text{supp} B_{i,p})} \leq (2p + 3)9p |\text{supp} B_{i,p}|^{-1/2}.
$$

Define $\tilde{R}_{i,p} := B_{i,p}^* w/w_i$ with the denominator $w$ from before, and $\tilde{R}_{i,p} := R_{i,p}|_{(a,b)} \circ \gamma|_{[a,b]}$. For $I \subseteq \{1 - p, \ldots, N - p\}$, we define the following Scott–Zhang type
operator

\[ P_{*,I} : L^2(\Gamma) \rightarrow X_* : \psi \mapsto \sum_{i \in I} \left( \int_{\text{supp} \hat{R}_{i,p}} R_{i,p}^*(t) \psi(y(t)) \, dt \right) \hat{R}_{i,p}. \]  

(5.9)

In [4, Section 3.1.2], a similar operator is considered for \( I = \{ 1 - p, \ldots, N - p \} \), and [4, Proposition 2.2] proves an analogous version of the following lemma.

**Lemma 5.3** The Scott–Zhang type operator (5.9) satisfies the following two properties:

(i) **Local projection property**: For \( T \in T_* \) with \( \{ i : T \subseteq \text{supp} \hat{R}_{i,p} \} \subseteq I \) and \( \psi \in L^2(\Gamma) \), the inclusion \( \psi|_{\omega_p^R(T)} \in X_*|_{\omega_p^R(T)} := \{ \xi|_{\omega_p^R(T)} : \xi \in X_* \} \) implies \( \psi|_T = (P_{*,I} \psi)|_T \).

(ii) **Local \( L^2 \)-stability**: For \( \psi \in L^2(\Gamma) \) and \( T \in T_* \), there holds

\[ \| P_{*,I} \psi \|_{L^2(T)} \leq C_{sz} \| \psi \|_{L^2(\omega_p^R(T))}, \]

where \( C_{sz} \) depends only on \( \kappa_{\text{max}}, p, w_{\text{max}}, \) and \( \gamma \).

**Proof** All NURBS basis functions which are non-zero on \( T \), have support in \( \omega_p^R(T) \). With this, (i) follows easily from the definition of \( P_{*,I} \). For stability (ii), we use

\[ \sum_{i \in I} \left( \int_{\text{supp} \hat{R}_{i,p}} R_{i,p}^*(t) \psi(y(t)) \, dt \right) \hat{R}_{i,p} \]

\[ \leq \sum_{i \in I} \left( \int_{\text{supp} \hat{R}_{i,p}} R_{i,p}^*(t) \psi(y(t)) \, dt \right) \| \hat{R}_{i,p} \|_{L^2(T)} \]

\[ \leq \sum_{i \in I} \| R_{i,p}^* \|_{L^2(\text{supp} \hat{R}_{i,p})} \| \psi \|_{L^2(\text{supp} \hat{R}_{i,p})} h_{*,T}^{1/2} \]

\[ \overset{(5.8)}{\leq} \sum_{i \in I} \| \psi \|_{L^2(\text{supp} \hat{R}_{i,p})} \overset{\leq}{=} \| \psi \|_{L^2(\omega_p^R(T))}. \]

Overall, the hidden constants depend only on \( \kappa_{\text{max}}, p, w_{\text{max}}, \) and \( \gamma \). \( \square \)

**Proof of Lemma 5.2** We choose

\[ I := \{ i : |\text{supp} \hat{R}_{i,p} \cap \Gamma \text{ \backslash } \omega_p^R([T_*] \cup [T_+]) | > 0 \}. \]

We prove that

\[ P_{*,I} (\Phi_+ - \Phi_*) = \begin{cases} \Phi_+ - \Phi_* & \text{on } \Gamma \text{ \backslash } \omega_p^R([T_*] \cup [T_+]), \\ 0 & \text{on } \bigcup([T_*] \cup [T_+]). \end{cases} \]  

(5.10)
To see this, let \( T \in T_* \) with \( T \subseteq \Gamma \setminus \omega_\ast^p([T_*] \setminus [T_+]) \). Then, \( \{ i : T \subseteq \text{supp} \tilde{R}_{i,p} \} \subseteq I \). It holds \( \omega_\ast^p(T) \subseteq \bigcup (\{T_* \} \cap [T_+]) \). This implies that no new knots are inserted in \( \omega_\ast^p(T) \). With Lemma 2.3(i), it follows \( \mathcal{X}_+^{\ast} \big|_{\omega_\ast^p(T)} = \mathcal{X}_+ \big|_{\omega_\ast^p(T)} \) and, in particular, \( (\Phi_+ - \Phi_\ast) \big|_{\omega_\ast^p(T)} \in \mathcal{X}_+ \big|_{\omega_\ast^p(T)} \). Hence Lemma 5.3(i) is applicable and proves \( P_{\ast,!} (\Phi_+ - \Phi_\ast) |_T = (\Phi_+ - \Phi_\ast) |_T \). For \( T \in T_* \) with \( T \subseteq \bigcup (\{T_* \} \setminus [T_+]) \), the assertion follows immediately from the definition of \( P_{\ast,!} \), since \( \tilde{R}_{i,p} |_T = 0 \) for \( i \in I \).

Let \( \tilde{N}_\ast := \{ z \in N_* : z \in \omega_\ast^p([T_*] \setminus [T_+]) \} \). For \( z \in \tilde{N}_\ast \), let \( \varphi_z \) be the \( P^1 \) hat function, i.e., \( \varphi_z(z') = \delta_{z,z'} \) for all \( z' \in \tilde{N}_\ast \), \( \text{supp}(\varphi_z) = \omega_\ast(z) \), and \( \partial_r \varphi_z \) is const. on \( T_{z,1} \) and \( T_{z,2} \), where \( \omega_\ast(z) = T_{z,1} \cup T_{z,2} \) with \( T_{z,1}, T_{z,2} \in T_* \). Because of Galerkin orthogonality and \( \sum_{z \in \tilde{N}_\ast} \varphi_z |_{\omega_\ast^p([T_*] \setminus [T_+])} = 1 \), we see

\[
\| \Phi_+ - \Phi_\ast \|^2_V = \left( f - V \Phi_\ast; (1 - P_{\ast,!})(\Phi_+ - \Phi_\ast) \right)_I \\
= \left( \sum_{z \in \tilde{N}_\ast} \varphi_z (f - V \Phi_\ast); (1 - P_{\ast,!})(\Phi_+ - \Phi_\ast) \right)_I.
\]

We abbreviate \( \Sigma := \sum_{z \in \tilde{N}_\ast} \varphi_z(f - V \Phi_\ast) \) and estimate with (M1), Lemma 5.3(ii) and Proposition 4.1

\[
\left( \Sigma ; \Phi_+ - \Phi_\ast \right) \leq \| \Sigma \|_{H^{1/2}(\Gamma)} \| \Phi_+ - \Phi_\ast \|_{H^{-1/2}(\Gamma)} \simeq \| \Sigma \|_{H^{1/2}(\Gamma)} \| \Phi_+ - \Phi_\ast \|_V.
\]

So far, we thus have proved

\[
\| \Phi_+ - \Phi_\ast \|_V \leq \| h_{\ast}^{-1/2} \Sigma \|_{L^2(\Gamma)} + \| \Sigma \|_{H^{1/2}(\Gamma)} \\
\leq \| h_{\ast}^{-1/2} (f - V \Phi_\ast) \|_{L^2(\omega_\ast^{p+1}([T_*] \setminus [T_+]))} + \| \Sigma \|_{H^{1/2}(\Gamma)}.
\]

Next, we use [25, Lemma 3.4], [24, Lemma 4.5], and \( |\partial_r \varphi_z| \simeq |\omega_\ast(z)|^{-1} \) to estimate

\[
\| \Sigma \|^2_{H^{1/2}(\Gamma)} \lesssim \sum_{z \in \tilde{N}_\ast} |\Sigma|^2_{H^{1/2}(\omega_\ast(z))} + \| h_{\ast}^{-1/2} \Sigma \|_{L^2(\Gamma)}^2 \\
\lesssim \sum_{z \in \tilde{N}_\ast} \| h_{\ast}^{1/2} \partial_r \Sigma \|_{L^2(\omega_\ast(z))}^2 + \| h_{\ast}^{-1/2} \Sigma \|_{L^2(\Gamma)}^2 \\
\lesssim \| h_{\ast}^{1/2} \partial_r \Sigma \|_{L^2(\Gamma)}^2 + \| h_{\ast}^{-1/2} \Sigma \|_{L^2(\Gamma)}^2.
\]
Optimal convergence for adaptive IGA boundary element methods… 173

depends only on \( \tilde{\kappa} \) (5.12). It holds

It remains to consider the term \( \| h^{-1/2}_* (f - V \Phi_*) \|_{L^2(\omega^{p+1}([T_* \setminus \{T_+\}))} \) of (5.11) and (5.12). It holds

\[
\| h^{-1/2}_* (f - V \Phi_*) \|_{L^2(\omega^{p+1}([T_* \setminus \{T_+\}))}^2 = \sum_{T \in T_* \setminus \{T_+\}} \| h^{-1/2}_* (f - V \Phi_*) \|_{L^2(T)}^2.
\] (5.13)

For any \( T \in T_* \), there is a function \( \psi_T \in \mathcal{X}_* \) with connected support, \( T \subseteq \text{supp}(\psi_T) \subseteq \omega_*^{p/2}(T) \) and \( \| 1 - \psi_T \|_{L^2(\text{supp}(\psi_T))}^2 \leq q |\text{supp}(\psi_T)| \) with some \( q \in (0, 1) \) which depends only on \( \bar{\kappa}_{\text{max}}, \gamma, p, w_{\text{min}}, \) and \( w_{\text{max}} \); see [25, (A1)–(A2), Theorem 4.4]. We use some Poincaré inequality (see, e.g., [18, Lemma 2.5]) to see

\[
\| f - V \Phi_* \|_{L^2(\text{supp}(\psi_T))}^2 \leq \frac{|\text{supp}(\psi_T)|^2}{2} \| \partial T (f - V \Phi_*) \|_{L^2(\text{supp}(\psi_T))}^2 + \frac{1}{|\text{supp}(\psi_T)|} \left| \int_{\text{supp}(\psi_T)} (f - V \Phi_*)(x) \, dx \right|^2.
\] (5.14)

The Galerkin orthogonality proves

\[
\left| \int_{\text{supp}(\psi_T)} (f - V \Phi_*)(x) \, dx \right|^2 = \left| \int_{\text{supp}(\psi_T)} (f - V \Phi_*)(x)(1 - \psi_T(x)) \, dx \right|^2 \leq \| f - V \Phi_* \|_{L^2(\text{supp}(\psi_T))}^2 q |\text{supp}(\psi_T)|.
\]

Using (5.14), we therefore get

\[
\| f - V \Phi_* \|_{L^2(\text{supp}(\psi_T))}^2 \leq \frac{|\text{supp}(\psi_T)|^2}{2} \| \partial T (f - V \Phi_*) \|_{L^2(\text{supp}(\psi_T))}^2 + q \| f - V \Phi_* \|_{L^2(\text{supp}(\psi_T))}^2,
\]

which implies

\[
\| f - V \Phi_* \|_{L^2(T)}^2 \leq \| h^{-1/2}_* (f - V \Phi_*) \|_{L^2(\omega^{p/2}(T))}^2 + q \| f - V \Phi_* \|_{L^2(\text{supp}(\psi_T))}^2,
\]

\( \odot \) Springer
Hence, we are led to

\[ \| h_{\star}^{-1/2} (f - V \Phi_{\star}) \|_{L^2(\omega_{p+1}([T_{\star}] \setminus [T_{+}])))}^2 \lesssim \| h_{\star}^{-1/2} \partial_{\Gamma} (f - V \Phi_{\star}) \|_{L^2(\omega_{[p/2]+p+1}([T_{\star}] \setminus [T_{+}])))}^2. \]

With

\[ R_{\star}(T_{+}) := \{ T \in T_{\star} : T \subseteq \omega_{[p/2]+p+1}([T_{\star}] \setminus [T_{+}]) \}, \]

we therefore conclude the proof.

Since we use a different mesh-refinement strategy, we cannot directly cite the following lemma from [8]. However, we may essentially follow the proof of [8, Proposition 4.12] verbatim. Details are left to the reader.

**Lemma 5.4** (Optimality of Dörfler marking) Define

\[ \overline{\theta}_{\text{opt}} := (1 + C_{\text{stab}}^2 C_{\text{rel}}^2)^{-1}. \]  

(5.15)

For all \( 0 < \overline{\theta} < \overline{\theta}_{\text{opt}} \) there is some \( 0 < q_{\text{opt}} < 1 \) such that for all refinements \([T_{+}] \in \mathcal{R}([T_{\star}])\) of \([T_{\star}] \in [T]\) the following implication holds true

\[ \rho_{+}^2 \leq q_{\text{opt}} \rho_{\star}^2 \implies \overline{\theta} \rho_{\star}^2 \leq \sum_{T \in R_{\star}(T_{+})} \rho_{\star}(T)^2. \]  

(5.16)

The constant \( q_{\text{opt}} \) depends only on \( \overline{\theta} \) and the constants \( C_{\text{stab}} \) of Lemma 5.1 and \( C_{\text{rel}} \) of Lemma 5.2.

The next lemma reads similarly as [8, Lemma 3.4]. Since we use a different mesh-refinement strategy and our estimator \( \rho \) does not satisfy the reduction axiom (A2), we cannot directly cite the result. However, the idea of the proof is the same. Indeed, one only needs a weaker version of the mentioned axiom.

**Lemma 5.5** (Quasi-monotonicity of \( \rho \)) For all refinements \([T_{+}] \in \mathcal{R}([T_{\star}])\) of \([T_{\star}] \in [T]\), there holds

\[ \rho_{+}^2 \leq C_{\text{mon}} \rho_{\star}^2, \]  

(5.17)

where \( C_{\text{mon}} > 0 \) depends only on the parametrisation \( \gamma \) and the constants \( C_{\text{inv}} \) of Proposition 4.1 and \( C_{\text{rel}} \) of Lemma 5.2.

**Proof** We split the estimator as follows

\[ \rho_{+}^2 = \sum_{T \in T_{+} \setminus T_{\star}} \rho_{+}(T)^2 + \sum_{T \in T_{\star} \cap T_{+}} \rho_{+}(T)^2. \]
For the first sum, we use (5.4), $\bigcup (T_+ \setminus T_s) = \bigcup (T_s \setminus T_+)$, and $\tilde{h}_+ \leq \tilde{h}_s$ to estimate

$$\sum_{T \in T_+ \setminus T_s} \rho_+(T)^2 = \| \tilde{h}_+^{1/2} \partial_\Gamma (f - V \Phi_+) \|_{L^2(\bigcup (T_+ \setminus T_s))}^2 \lesssim \left( \| \Phi_+ - \Phi_\ast \|_{\tilde{H}^{-1/2}(\Gamma)} + \| \tilde{h}_+^{1/2} \partial_\Gamma (f - V \Phi_\ast) \|_{L^2(\bigcup (T_s \setminus T_+))} \right)^2 \leq 2 \| \Phi_+ - \Phi_\ast \|_{\tilde{H}^{-1/2}(\Gamma)}^2 + 2 \sum_{T \in T_+ \setminus T_s} \rho_+(T)^2.$$ 

For the second sum, we use Lemma 5.1 to see

$$\sum_{T \in T_s \cap T_+} \rho_+(T)^2 \leq 2 \sum_{T \in T_s \cap T_+} \rho_+(T)^2 + 2 C_{\text{stab}}^2 \| \Phi_+ - \Phi_\ast \|_{\tilde{H}^{-1/2}(\Gamma)}^2.$$ 

We end up with

$$\rho_+^2 \lesssim \| \Phi_+ - \Phi_\ast \|_{\tilde{H}^{-1/2}(\Gamma)}^2 + \rho_\ast^2.$$ 

Lemma 5.2 concludes the proof. \hfill \Box

The optimality in Theorem 3.2 essentially follows from the following lemma. It was inspired by an analogous version from [8, Lemma 4.14].

**Lemma 5.6** Suppose that $\phi \in \mathbb{A}_s$ for some $s > 0$. Then, for all $0 < \bar{\theta} < \bar{\theta}_{\text{opt}}$ there exist constants $C_1, C_2 > 0$ such that for all meshes $[T_s] \in [\mathbb{T}]$ there exists some refinement $[T_+] \in \mathcal{R}([T_s])$ such that the corresponding set $\mathcal{R}_s(T_+) \subseteq T_s$ from Lemma 5.2 satisfies

$$|\mathcal{R}_s(T_+)| \leq C_1 C_2^{1/s} \| \phi \|_{\mathbb{A}_s}^{1/s} \rho_\ast^{-1/s},$$

and

$$\bar{\theta} \rho_\ast^2 \leq \sum_{T \in \mathcal{R}_s(T_+)} \rho_+(T)^2.$$ 

With the constants $C_{\text{rel}}, C_{\text{mon}}$, and $q_{\text{opt}}$ from Lemmas 5.2, 5.4 and 5.5, it holds $C_1 = 2C_{\text{rel}}$ and $C_2 = (C_{\text{mon}} q_{\text{opt}}^{-1})^{1/2}$.

**Proof** We set $\alpha := C_{\text{mon}}^{-1} q_{\text{opt}}$ with the constants of Lemma 5.4 and Lemma 5.5, and $\delta^2 := \alpha \rho_\ast^2$.

**Step 1** There exists $[T_\delta] \in [\mathbb{T}]$ with

$$\rho_\delta \leq \delta \quad \text{and} \quad |\mathcal{K}_\delta| - |\mathcal{K}_0| \leq \| \phi \|_{\mathbb{A}_s}^{1/s} \delta^{-1/s}.$$ 

 Springer
Let \( N \in \mathbb{N}_0 \) be minimal with \((N + 1)^{-s} \| \phi \|_{\mathcal{A}_s} \leq \delta \). If \( N = 0 \), then \( \rho_0 \leq \| \phi \|_{\mathcal{A}_s} \leq \delta \) and we can choose \([T_\delta] = [T_0]\). If \( N > 0 \), minimality of \( N \) implies \( N^{-s} \| \phi \|_{\mathcal{A}_s} > \delta \) or equivalently \( N < \| \phi \|_{\mathcal{A}_s}^{1/s} \delta^{-1/s} \). We choose \([T_\delta] \in [T_N]\) such that
\[
\rho_\delta = \min_{[T_\nu] \in [T_N]} \rho_\nu.
\]
By the definition of \( \| \phi \|_{\mathcal{A}_s} \), we see
\[
\rho_\delta \leq (N + 1)^{-s} \| \phi \|_{\mathcal{A}_s} \leq \delta.
\]
By the definition of \([T_N]\), we see
\[
|K_\delta| - |K_0| \leq N < \| \phi \|_{\mathcal{A}_s}^{1/s} \delta^{-1/s}.
\]

**Step 2** We consider the overlay \([T_+]:=[T_\star] \oplus [T_\delta]\) of (M2). Quasi-monotonicity shows
\[
\rho_\star^2 \leq C_{\text{mon}} \rho_\delta^2 \leq C_{\text{mon}} \delta^2 = q_{\text{opt}} \rho_\star^2. \tag{5.20}
\]

**Step 3** Finally, the assumptions on the refinement strategy are used. The overlay estimate and Step 1 give
\[
|K_+| - |K_\star| \leq (|K_\delta| + |K_\star| - |K_0|) - |K_\star| = |K_\delta| - |K_0| \leq \| \phi \|_{\mathcal{A}_s}^{1/s} \delta^{-1/s}.
\]
Lemma 5.2 and (2.12) show
\[
|R_\star(T_+)| \leq C_{\text{rel}} ||T_\star||[T_+] \leq 2C_{\text{rel}} (|K_+| - |K_\star|).
\]
Combining the last two estimates, we end up with
\[
|R_\star(T_+)| \leq 2C_{\text{rel}} \| \phi \|_{\mathcal{A}_s}^{1/s} \alpha^{-1/2} \rho_\star^{-1/s}.
\]
This proves (5.18) with \( C_1 = 2C_{\text{rel}} \) and \( C_2 = \alpha^{-1/2} \). By (5.20) we can apply Lemma 5.4 and see (5.19). \( \square \)

So far, we have only considered the auxiliary estimator \( \rho_\star \). In particular, we did not use Algorithm 3.1, but only the refinement strategy \( \mathcal{R}(\cdot) \) itself. For the proof of optimal convergence (3.7), we proceed similarly as in [8, Theorem 8.4 (ii)].

**Proof of (3.7)** Due to (5.2), there is a constant \( C \geq 1 \) which depends only on \( \tilde{\kappa}_\text{max} \) with \( \mu_2^2 \leq C \rho_\star^2 \) for all \([T_\star] \in [\mathbb{T}]\). We set \( \theta_{\text{opt}} := \theta_{\text{opt}}/C \) and \( \overline{\theta} := C \theta \) and suppose that \( \theta \) is sufficiently small, namely, \( \theta < \theta_{\text{opt}} \) and hence \( \overline{\theta} < \theta_{\text{opt}} \). Let \( \ell \in \mathbb{N}_0 \) and
Choose a refinement \([T_+]\) of \([T]\) as in Lemma 5.6. In particular, the set \(R_j(T_+)\) satisfies the Dörfler marking (5.20). According to (5.2), this implies

\[
\theta \mu_j \leq \bar{\theta} \rho_j \leq \sum_{T \in R_j(T_+)} \rho_j(T)^2 \leq \sum_{z \in N_j \cap \bigcup R_j(T_+)} \mu_j(z)^2,
\]

i.e., the set \(N_j \cup \bigcup R_j(T_+)\) satisfies the Dörfler marking (3.3) from Algorithm 3.1. Since the chosen set \(M_j\) of Algorithm 3.1 has essentially minimal cardinality, we see with (5.18) that

\[
|M_j| \leq C_{\text{mark}} |N_j \cap \bigcup R_j(T_+)| \leq 2C_{\text{mark}} |R_j(T_+)| \leq 2C_{\text{mark}} C_2 \frac{1}{s} \|\phi\|_{H^s_\mu} \rho_j^{-1/s}
\]

With the mesh-closure estimate of (M3), we get

\[
|K_\ell| - |K_0| \leq C_{\text{mesh}} \sum_{j=0}^{\ell-1} |M_j| \leq 2C_{\text{mark}} C_{\text{mesh}} C_2 \frac{1}{s} \|\phi\|_{H^s_\mu} \sum_{j=0}^{\ell-1} \rho_j^{-1/s}
\]

\[
\leq 2C_{\text{mark}} C_{\text{mesh}} C_2 \frac{1}{s} \|\phi\|_{H^s_\mu} \sum_{j=0}^{\ell-1} \mu_j^{-1/s}.
\]

Linear convergence (3.5) shows

\[
\mu_\ell \leq C_{\text{lin}} q_{\text{lin}}^{\ell-j} \mu_j \quad \text{for all } j = 0, \ldots, \ell.
\]

Hence,

\[
|K_\ell| - |K_0| \leq 2C_{\text{mark}} C_{\text{mesh}} C_2 \frac{1}{s} \|\phi\|_{H^s_\mu} \sum_{j=0}^{\ell-1} \mu_j^{-1/s}
\]

\[
\leq 2C_{\text{mark}} C_{\text{mesh}} C_1 (C_2 C_{\text{lin}}) \frac{1}{s} \|\phi\|_{H^s_\mu} \mu_\ell^{-1/s} \sum_{j=0}^{\ell-1} (q_{\text{lin}}^{1/s})^{\ell-j}
\]

\[
\leq (C_2 C_{\text{lin}} C_1) \frac{1}{1 - q_{\text{lin}}^{1/s}} \|\phi\|_{H^s_\mu} \mu_\ell^{-1/s}.
\]

This concludes the proof. \(\square\)

6 Proof of Theorem 3.4, plain convergence (3.10)

To prove convergence of Algorithm 3.1 driven by the Faermann estimators \(\eta_\ell\), we apply an abstract result of [23, Section 2] which is recalled in the following: Let \(H\) be a Hilbert space with dual space \(H^*\) and \(V : H \to H^*\) be a linear elliptic operator and \(f \in H^*\). Let \(X_\ell(f)\) be a sequence of finite dimensional nested subspaces
of $\mathcal{H}$, i.e., $\mathcal{X}_\ell(f) \subseteq \mathcal{X}_{\ell+1}(f)$, with Galerkin approximations $\Phi_\ell(f) \in \mathcal{X}_\ell(f)$ for the equation $V \phi = f$. Further, let $(\mathcal{N}_\ell(f))_{\ell \in \mathbb{N}_0}$ be a sequence of arbitrary finite sets and

$$\eta_\ell(f) := \eta_\ell(f, \mathcal{N}_\ell(f)) \text{ with } \eta_\ell(f, \mathcal{E}_\ell) := \left( \sum_{z \in \mathcal{E}_\ell} \eta_\ell(f, z)^2 \right)^{1/2} < \infty \text{ for all } \mathcal{E}_\ell \subseteq \mathcal{N}_\ell(f)$$

some heuristical error estimator, where we only require $\eta_\ell(f, z) \geq 0$ for each $z \in \mathcal{N}_\ell(f)$. Let $(\mathcal{M}_\ell(f))_{\ell \in \mathbb{N}_0}$ be a sequence of marked elements with $\mathcal{M}_\ell(f) \subseteq \mathcal{N}_\ell(f)$ which satisfies the Dörfler marking, i.e.,

$$\theta \eta_\ell(f)^2 \leq \eta_\ell(f, \mathcal{M}_\ell(f))^2.$$

Additionally let

$$\tilde{\rho}_\ell(f) := \tilde{\rho}_\ell(f, \mathcal{N}_\ell(f)) \text{ with } \tilde{\rho}_\ell(f, \mathcal{E}_\ell) := \left( \sum_{z \in \mathcal{E}_\ell} \tilde{\rho}_\ell(f, z)^2 \right)^{1/2} < \infty \text{ for all } \mathcal{E}_\ell \subseteq \mathcal{N}_\ell(f)$$

be an auxiliary error estimator with local contributions $\tilde{\rho}_\ell(f, z) \geq 0$. Then, there holds the following convergence result.

**Lemma 6.1** Suppose that $D \subseteq \mathcal{H}^*$ is a dense subset of $\mathcal{H}^*$ such that for all $f \in D$ and all $\ell \in \mathbb{N}_0$ there is a set $\mathcal{R}_\ell(f) \subseteq \mathcal{M}_\ell(f)$ such that the following assumptions (A1)–(A3) hold:

(A1) $\eta_\ell(f)$ is a local lower bound of $\tilde{\rho}_\ell(f)$: There is a constant $C_1 > 0$ such that

$$\eta_\ell(f, \mathcal{M}_\ell(f)) \leq C_1 \tilde{\rho}_\ell(f, \mathcal{R}_\ell(f)) \text{ for all } \ell \in \mathbb{N}_0.$$

(A2) $\tilde{\rho}_\ell(f)$ is contractive on $\mathcal{R}_\ell(f)$: There is a constant $C_2$ such that for all $\ell \in \mathbb{N}_0$, $m \in \mathbb{N}$ and all $\delta > 0$, it holds

$$C_2^{-1} \tilde{\rho}_\ell(f, \mathcal{R}_\ell(f))^2 \leq \tilde{\rho}_\ell(f)^2 - \frac{1}{1 + \delta} \tilde{\rho}_{\ell+m}(f)^2 + (1 + \delta^{-1})C_2 \| \Phi_{\ell+m}(f) \|_{\mathcal{H}^*}^2 \Phi_\ell(f) \|_{\mathcal{H}^*}^2.$$

In addition, we suppose for all $f \in \mathcal{H}^*$ validity of:

(A3) $\eta_\ell$ is stable on $\mathcal{M}_\ell(f)$ with respect to $f$: there is a constant $C_3 > 0$ such that, for all $\ell \in \mathbb{N}_0$ and $f' \in \mathcal{H}^*$, it holds

$$|\eta_\ell(f, \mathcal{M}_\ell(f)) - \eta_\ell(f', \mathcal{M}_\ell(f))| \leq C_3 \| f - f' \|_{\mathcal{H}^*}.$$

Then, there holds convergence $\lim_{\ell \to \infty} \eta_\ell = 0$ for all $f \in \mathcal{H}^*$. 

\(\copyright\) Springer
Proof of plain convergence (3.10) We choose \( \mathcal{H} = \tilde{H}^{-1/2}(\Gamma), \mathcal{H}^* = H^{1/2}(\Gamma) \), \( V \) the weakly-singular integral operator (1.1). Moreover, Algorithm 3.1 generates the transformed NURBS spaces \( X_\ell(f) \), the set of nodes \( N_\ell(f) \), the Faermann estimator \( \eta_\ell(f) \) and the set of marked nodes \( M_\ell(f) \). We use the mesh-size function \( \tilde{h}_\ell \) of Proposition 4.2 to define

\[
\tilde{\rho}_\ell(f, z) := \| \tilde{h}_\ell^{1/2} \partial \Gamma (f - V \Phi_\ell) \|_{L^2(\omega(z))} \quad \text{for all} \ z \in N_\ell, \tag{6.1}
\]

if \( f \) is in the dense set \( D = H^1(\Gamma) \). We aim to apply Lemma 6.1 and show in the following that (A1)–(A2) hold for all \( f \in H^1(\Gamma) \) even with \( R_\ell(f) = M_\ell(f) \) and that (A3) holds for all \( f \in H^{1/2}(\Gamma) \). Then, Lemma 6.1 shows convergence (3.10) of the Faermann estimator.

(A1) Of Lemma 6.1 follows immediately from [24, Theorem 4.3], where the constant \( C_1 \) depends only on \( \tilde{\kappa}_{\text{max}}, p, \) and \( \gamma \).

(A3) Can be proved exactly as in [23, Section 2.4] as \( \eta_\ell \) is efficient (see [25, Theorem 3.1]) and has a semi-norm structure. The constant \( C_3 \) depends only on \( \Gamma \).

The only challenging part is the proof of (A2) for fixed \( f \in H^1(\Gamma) \). We proceed similarly as in the proof of [23, Theorem 3.1]. In the following, we skip the dependence of \( f \). The heart of the matter are the estimates \( \tilde{h}_{\ell+1} \leq q_{\text{ctr}} \tilde{h}_\ell \) on \( \omega_\ell(M_\ell) \) and \( \tilde{h}_{\ell+1} \leq \tilde{h}_\ell \) on \( \Gamma \), which follow from Proposition 4.2 and

\[
M_\ell \subset \bigcup ([T_\ell] \setminus [T_{\ell+1}]).
\]

This shows

\[
\tilde{h}_\ell - \tilde{h}_{\ell+m} \geq \tilde{h}_\ell - \tilde{h}_{\ell+1} \geq (1 - q_{\text{ctr}}) \tilde{h}_\ell \chi_{\omega_\ell(M_\ell)} \quad \text{for all} \ \ell \in \mathbb{N}_0 \text{ and } m \in \mathbb{N}.
\]

Hence, the estimator \( \tilde{\rho}_\ell \) satisfies

\[
(1 - q_{\text{ctr}}) \tilde{\rho}_\ell(M_\ell)^2 / 2 \leq (1 - q_{\text{ctr}}) \int_{\omega_\ell(M_\ell)} \tilde{h}_\ell |\partial \Gamma (f - V \Phi_\ell)|^2 \, dx
\]

\[
\leq \int_{\Gamma} \tilde{h}_\ell |\partial \Gamma (f - V \Phi_\ell)|^2 - \int_{\Gamma} \tilde{h}_{\ell+m} |\partial \Gamma (f - V \Phi_\ell)|^2 \, dx
\]

\[
= \| \tilde{h}_\ell^{1/2} \partial \Gamma (f - V \Phi_\ell) \|_{L^2(\Gamma)}^2 - \| \tilde{h}_{\ell+m}^{1/2} \partial \Gamma (f - V \Phi_\ell) \|_{L^2(\Gamma)}^2.
\]

Here, the factor \( 1/2 \) on the left-hand side stems from the fact that each node patch consists (generically) of two elements. This fact also shows \( \| \tilde{h}_\ell^{1/2} \partial \Gamma (f - V \Phi_\ell) \|_{L^2(\Gamma)}^2 = \tilde{\rho}_\ell^2 / 2 \). The Young inequality \((c + d)^2 \leq (1 + \delta)c^2 + (1 + \delta^{-1})d^2\) for \( c, d \geq 0 \), together with the triangle inequality shows
\[(1 - q_{\text{ctr}}) \bar{\rho}_{\ell}(\mathcal{M}_{\ell})^2/2 \leq \tilde{\rho}_{\ell}^2/2 - \frac{1}{1 + \delta} \tilde{\rho}_{\ell+m}^2/2 + \frac{1 + \delta^{-1}}{1 + \delta} \| \tilde{h}_{\ell+m}^{1/2} \partial_{\Gamma} V(\Phi_{\ell} - \Phi_{\ell+m}) \|_{L^2(\Gamma)}^2.\]

Finally, we use Proposition 4.1 and see
\[\| \tilde{h}_{\ell+m}^{1/2} \partial_{\Gamma} V(\Phi_{\ell} - \Phi_{\ell+m}) \|_{L^2(\Gamma)} \leq \tilde{C}_{\text{inv}} \| \Phi_{\ell} - \Phi_{\ell+m} \|_{\tilde{H}^{-1/2}(\Gamma)}.\]

with a constant \(\tilde{C}_{\text{inv}} > 0\) which depends only on \(C_{\text{inv}}\) and \(h_\star \simeq \tilde{h}_\star\). This yields
\[(1 - q_{\text{ctr}}) \bar{\rho}_{\ell}(\mathcal{M}_{\ell})^2/2 \leq \tilde{\rho}_{\ell}^2/2 - \frac{1}{1 + \delta} \tilde{\rho}_{\ell+m}^2/2 + \frac{1 + \delta^{-1}}{1 + \delta} \tilde{C}_{\text{inv}}^2 \| \Phi_{\ell} - \Phi_{\ell+m} \|_{\tilde{H}^{-1/2}(\Gamma)}^2.\]

and concludes the proof of (A2) with \(C_2 = \max(1 - q_{\text{ctr}}, 2\tilde{C}_{\text{inv}}^2).\)

\section*{Acknowledgements}
Open access funding provided by [TU Wien (TUW)]. The authors acknowledge support through the Austrian Science Fund (FWF) under Grant P27005 \textit{Optimal adaptivity for BEM and FEM-BEM coupling}, P29096 \textit{Optimal isogeometric boundary element methods} and the FWF doctoral school \textit{Dissipation and Dispersion in Nonlinear PDEs} funded under Grant W1245. Moreover, MF was supported by the Australian Research Council under grant number DP160101755.
