Pathwidth, trees, and random embeddings

James R. Lee† Anastasios Sidiropoulos‡

Abstract

We prove that, for every integer $k \geq 1$, every shortest-path metric on a graph of pathwidth $k$ embeds into a distribution over random trees with distortion at most $c(k)$, independent of the graph size. A well-known conjecture of Gupta, Newman, Rabinovich, and Sinclair [GNRS04] states that for every minor-closed family of graphs $\mathcal{F}$, there is a constant $c(\mathcal{F})$ such that the multi-commodity max-flow/min-cut gap for every flow instance on a graph from $\mathcal{F}$ is at most $c(\mathcal{F})$. The preceding embedding theorem is used to prove this conjecture whenever the family $\mathcal{F}$ does not contain all trees.

1 Introduction

We view an undirected graph $G = (V, E)$ as a topological template that supports a number of different geometries. Such a geometry is specified by a non-negative length function $\text{len} : E \rightarrow \mathbb{R}$ on edges, which induces a shortest-path pseudometric $d_{\text{len}}$ on $V$, with

$$d_{\text{len}}(u, v) = \text{length of the shortest path between } u \text{ and } v \text{ in } G,$$

where a pseudometric might have $d_{\text{len}}(u, v) = 0$ for some pairs $u, v \in V$ with $u \neq v$. From this point of view, we are interested in properties which hold simultaneously for all geometries supported on $G$, or even for all geometries supported on a family of graphs $\mathcal{F}$.

In the seminal works of Linial-London-Rabinovich [LLR95] and Aumann-Rabani [AR98], and later Gupta-Newman-Rabinovich-Sinclair [GNRS04], the geometry of graphs is related to the classical study of the relationship between flows and cuts.

Multi-commodity flows and $L_1$ embeddings. For a metric space $(X, d)$, we use $c_1(X, d)$ to denote the $L_1$ distortion of $(X, d)$, i.e. the infimum over all numbers $D$ such that $X$ admits an embedding $f : X \rightarrow L_1$ with

$$d(x, y) \leq \|f(x) - f(y)\|_1 \leq D \cdot d(x, y)$$

for all $x, y \in X$. Here, we have $L_1 = L_1([0, 1])$, which can be replaced by the sequence space $\ell_1$ when $X$ is finite.

Corresponding to the preceding discussion, for a graph $G = (V, E)$ we write $c_1(G) = \sup c_1(V, d)$ where $d$ ranges over all metrics supported on $G$, and for a family $\mathcal{F}$ of graphs, we write $c_1(\mathcal{F}) = \sup c_1(G)$. 

---

†A portion of the results in this paper were announced at the 41st Annual Symposium on the Theory of Computing [LS09].

sup_{G \in \mathcal{F}} c_1(G)$. Thus for a family $\mathcal{F}$ of finite graphs, $c_1(\mathcal{F}) \leq D$ if and only if every geometry supported on a graph in $\mathcal{F}$ embeds into $L_1$ with distortion at most $D$.

On the other hand, one has the notion of a multi-commodity flow instance in $G$ which is specified by a pair of non-negative mappings $\text{cap} : E \rightarrow \mathbb{R}$ and $\text{dem} : V \times V \rightarrow \mathbb{R}$. We write $\text{maxflow}(G; \text{cap}, \text{dem})$ for the value of the maximum concurrent flow in this instance, which is the maximal value $\varepsilon$ such that a flow of value $\varepsilon \cdot \text{dem}(u, v)$ can be simultaneously routed between every pair $u, v \in V$ while not violating the given edge capacities.

A natural upper bound on $\text{maxflow}(G; \text{cap}, \text{dem})$ is given by the sparsity of any cut $S \subseteq V$:

$$\Phi(S; \text{cap}, \text{dem}) = \frac{\sum_{u \in V} \text{cap}(u, v) |1_S(u) - 1_S(v)|}{\sum_{u, v \in V} \text{dem}(u, v) |1_S(u) - 1_S(v)|},$$

where $1_S : V \rightarrow \{0, 1\}$ is the indicator function for membership in $S$. In the case where $\text{dem}(u, v) > 0$ for exactly one pair $u, v$, also known as single-commodity flow [FF56], minimizing the upper bound $\Phi$ computes the minimum $u$-$v$ cut in $G$, and the max-flow/min-cut theorem states that this upper bound is achieved by the corresponding maximum flow.

In general, we write $\text{gap}(G)$ for the maximum ratio between the upper bounds given by $\Phi$ and the value of the flow, over all multi-commodity flow instances on $G$. This is the multi-commodity max-flow/min-cut gap for $G$. Now we can state the fundamental relationship between the geometry of graphs and the flows they support:

**Theorem 1.1** ([LLR95, GNRS04]). For every graph $G$, $c_1(G) = \text{gap}(G)$.

In particular, combined with the techniques of [LLR95, LLR95], this implies that there exists a $c_1(G)$-approximation for the general Sparsest Cut problem on a graph $G$. Motivated by this connection, Gupta, Newman, Rabinovich, and Sinclair sought to characterize the graph families $\mathcal{F}$ such that $c_1(\mathcal{F}) < \infty$, and they posed the following conjecture.

**Conjecture 1** ([GNRS04]). For every family of finite graphs $\mathcal{F}$, one has $c_1(\mathcal{F}) < \infty$ if and only if $\mathcal{F}$ forbids some minor.

We refer to Section 1.3 for a review of graph minors. Progress on the preceding conjecture has been limited. Classical work of Okamura and Seymour [OSS81] implies that $c_1(\text{Outerplanar}) = 1$, where Outerplanar denotes the class of outerplanar graphs (planar graphs where all vertices lie on a single face). Gupta, Newman, Rabinovich, and Sinclair [GNRS04] proved that $c_1(\text{Treewidth}(2)) = O(1)$, where Treewidth($k$) denotes the family of all graphs of treewidth at most $k$ (see, e.g. [Die05] for a discussion of treewidth, or Section 1.3 for the relevant definitions). This was improved to $c_1(\text{Treewidth}(2)) = 2$ in [LR10, CILV08]. Finally, in [CGN+06], it is shown that $c_1(\text{Outerplanar}(k)) < \infty$ for all $k \in \mathbb{N}$, where Outerplanar($k$) denotes the class of $k$-outerplanar graphs. We remark that a strengthening of Conjecture [GNRS04] regarding integer multi-commodity flows, has been investigated by Chekuri, Shepherd, and Weibel [CSW10]. The present paper is devoted to proving the following special case of Conjecture [GNRS04].

**Theorem 1.2.** Every minor-closed family $\mathcal{F}$ which does not contain every possible tree satisfies $c_1(\mathcal{F}) < \infty$. Equivalently, $c_1(\mathcal{F}) < \infty$, and the multi-commodity max-flow/min-cut gap for $\mathcal{F}$ is uniformly bounded, i.e. $\text{gap}(\mathcal{F}) < \infty$, whenever $\mathcal{F}$ has bounded pathwidth.

We remark that Theorem 1.2 implies a polynomial-time $O(1)$-approximation algorithm for the general Sparsest Cut problem on graphs of bounded pathwidth. Recently, a more general $O(1)$-approximation algorithm for graphs of bounded treewidth has been obtained by Chlamtac, Krauthgamer, and Raghavendra [CKR10].
1.1 Simplifying the topology with random embeddings

A basic question is whether one can embed a graph metric $G$ into a graph metric $H$ with a simpler topology (for example, perhaps $G$ is planar and $H$ is a tree), where the embedding is required to have small distortion, i.e. such that every pairwise distance changes by only a bounded amount. The viability of this approach as a general method was ruled out by Rabinovich and Raz [RR98]. For instance, $\Omega(n)$ distortion is required to embed an $n$-cycle into a tree. In general (see [CG04]), if all metrics supported on a subdivision of some graph $G$ can be embedded with distortion $O(1)$ into metrics supported on a family $\mathcal{F}$, then $G$ is a minor of some graph in $\mathcal{F}$, implying that we have not obtained a reduction in topological complexity.

On the other hand, a classical example attributed to Karp [Kar89] shows that random reductions might still be effective: If one removes a uniformly random edge from the $n$-cycle, this gives an embedding into a random tree which has distortion at most 2 “in expectation.” More formally, if $(X,d)$ is any finite metric space, and $\mathcal{Y}$ is a family of finite metric spaces, we say that $(X,d)$ admits a stochastic $D$-embedding into $\mathcal{Y}$ if there exists a random metric space $(Y,d_Y) \in \mathcal{Y}$ and a random mapping $F : X \rightarrow Y$ such that the following two properties hold.

**Non-contracting.** With probability one, for every $x,y \in X$, we have $d_Y(F(x),F(y)) \geq d(x,y)$.

**Low-expansion.** For every $x,y \in X$,

$$\mathbb{E} \left[ d_Y(F(x),F(y)) \right] \leq D \cdot d(x,y).$$

For two graph families $\mathcal{F}$ and $\mathcal{G}$, we write $\mathcal{F} \sim \mathcal{G}$ if there exists a $D \geq 1$ such that every metric supported on $\mathcal{F}$ admits a stochastic $D$-embedding into the family of metrics supported on $\mathcal{G}$. We will write $\mathcal{F} \stackrel{D}{\sim} \mathcal{G}$ if we wish to emphasize the particular constant. Finally, we write $\mathcal{F} \not\sim \mathcal{G}$ if no such $D$ exists. The relationship with Conjecture [I] is given by the following simple lemma (see, e.g. [GNRS04]).

**Lemma 1.3.** If $\mathcal{F} \sim \mathcal{G}$, then $c_1(\mathcal{F}) \leq D \cdot c_1(\mathcal{G})$.

At first glance, $\sim$ seems like a powerful operation; indeed, in [GNRS04] it is proved that OuterPlanar $\sim$ Trees, where OuterPlanar and Trees are the families of outerplanar graphs and connected, acyclic graphs, respectively. In general, if $L$ is a finite list of graphs, we will write $\mathcal{E}L$ for the family of all graphs which do not have a member of $L$ as a minor. The preceding result can be restated as $\mathcal{E}\{K_{2,3}\} \sim \mathcal{E}\{K_3\}$, where $K_n$ and $K_{m,n}$ denote the complete and complete bipartite graphs, respectively. Unfortunately, [GNRS04] also showed that this cannot be pushed much further: $\mathcal{E}\{K_4\} \not\sim \mathcal{E}\{K_3\}$. Restated, this means that even graphs of treewidth 2 cannot be stochastically embedded into trees.

These lower bounds were extended in [CG04] to show that Treewidth($k+3$) $\not\sim$ Treewidth($k$) for any $k \geq 1$. Finally, in [CJLV08], these results are extended to any family with a weak closure property, which we describe next.

**Sums of graphs.** We now introduce a graph operation which will be useful in stating our results. Suppose that $H$ and $G$ are two graphs and $C_H, C_G$ are $k$-cliques in $H$ and $G$ respectively, for some $k \geq 1$. One defines the $k$-sum of $H$ and $G$ as the graph $H \circ_k G$ which results from taking the disjoint union of $H$ and $G$ and then identifying the two cliques $C_H$ and $C_G$, and possibly removing a subset of the clique edges. We remark that the notation is somewhat ambiguous, as both the
cliques and their identifications are implicit. For a family of graphs \( F \), we write \( \oplus_k F \) for the closure of \( F \) under \( i \)-sums for every \( i = 1, 2, \ldots, k \). With this notation in hand, we can state the following theorem.

**Theorem 1.4 ([CJLV08])**. If \( F \) and \( G \) are families of graphs and \( G \) is minor-closed, then \( \oplus_2 F \Rightarrow G \) implies \( F \subseteq G \).

In fact, one case of this theorem relies on Theorem 1.7 proved in the present paper, which states that for every \( k = 1, 2, \ldots \), we have \( \text{Trees} \cap \text{Pathwidth}(k+1) \not\Rightarrow \text{Pathwidth}(k) \), where \( \text{Pathwidth}(k) \) denotes the class of pathwidth-\( k \) graphs (see Section 1.3 for the relevant definitions).

Theorem 1.4 implies, for example, that \( \text{Planar} \cap \text{Treewidth}(k+1) \not\Rightarrow \text{Treewidth}(k) \) for any \( k \geq 1 \), where \( \text{Planar} \) is the family of planar graphs, since planar graphs and bounded treewidth graphs are both closed under 2-sums. The assumptions of the preceding theorem suggest that even random embeddings are not particularly useful for reducing the topology when \( \oplus_2 F = F \). However, some recent reductions suggest that when \( \oplus_2 F \neq F \), the situation is more hopeful.

In [CGN+06], it is proved that \( \text{Outerplanar}(k) \Rightarrow \text{Trees} \). Perhaps more surprisingly, it is shown in [IS07] that \( \text{Genus}(g) \Rightarrow \text{Planar} \), where \( \text{Genus}(g) \) is the family of graphs embedded on an orientable surface of genus \( g \), and \( \text{Genus}(0) = \text{Planar} \). Note that while trees and planar graphs are closed under 2-sums, neither \( \text{Outerplanar}(k) \) nor \( \text{Genus}(g) \) are for \( k \geq 1 \) and \( g \geq 1 \).

It should be noted that an extensive amount of work has been done on embedding finite metric spaces into distributions over trees, where the distortion is allowed to depend on \( n \), the number of points in the metric space; see, e.g. [Bar96, Bar98, FRT04]. These results are not particularly useful for us since we desire bounds that are independent of \( n \).

### 1.2 Results and techniques

We now discuss the main results of the paper, along with the techniques that go into proving them.

In [GNRS04], it is proved that \( c_1(\text{Treewidth}(2)) < \infty \), and later works [LR10, CJLV08] nailed down the precise dependence \( c_1(\text{Treewidth}(2)) = 2 \). Resolving whether \( c_1(\text{Treewidth}(3)) \) is finite seems quite difficult, and is a well-known open problem. In fact, perhaps the simplest “width 3” problem (which was open until the present work) involves the family \( \text{Pathwidth}(3) \) (recall that \( \text{Pathwidth}(k) \subseteq \text{Treewidth}(k) \) denotes the family of graphs of pathwidth at most \( k \); see Section 1.3). These families are fundamental in the graph minor theory (see e.g. [RS83, Lov06]); see Lemma 1.9 for an inductive definition.

Our main technical theorem shows that graphs of bounded path width can be randomly embedded into trees. In fact, the theorem shows something slightly stronger, that the target trees themselves can be taken to have bounded path width.

**Theorem 1.5.** For every \( k \in \mathbb{N} \), \( \text{Pathwidth}(k) \Rightarrow \text{Trees} \cap \text{Pathwidth}(k) \).

In particular, this verifies Conjecture 11 for graphs of bounded path width. Robertson and Seymour [RS83] showed that a minor-closed family \( F \) excludes a forest if and only if \( F \subseteq \text{Pathwidth}(k) \) for some \( k \in \mathbb{N} \).

**Corollary 1.6.** If \( T \) is any tree, then \( \mathcal{E}\{T\} \Rightarrow \text{Trees} \).

As a consequence, we resolve Conjecture 11 whenever \( F \) forbids some tree. From Lemma 1.3, we obtain Theorem 1.2. We remark that Theorem 1.2 was unknown even for \( F = \text{Pathwidth}(3) \).

In Section 4, we complement our upper bound by proving the following theorem.
**Theorem 1.7.** For every \( k \in \mathbb{N} \), \( \text{Pathwidth}(k + 1) \cap \text{Trees} \not\sim \text{Pathwidth}(k) \).

This result serves two purposes. First, it shows that our proof of Theorem\[1.5\] which embeds \( \text{Pathwidth}(k) \) directly into trees cannot proceed by inductively reducing the pathwidth by one. Secondly, it is needed in the proof of Theorem\[1.4\] in the case when \( \mathcal{F} \) contains only trees (the techniques of\[CJLV08\] handle the case when \( \mathcal{F} \) contains at least one cycle).

### 1.3 Preliminaries

We now review some basic definitions and notions which appear throughout the paper.

**Graphs and metrics.** We deal exclusively with finite graphs \( G = (V, E) \) which are free of loops and parallel edges. We will also write \( V(G) \) and \( E(G) \) for the vertex and edge sets of \( G \), respectively. A metric graph is a graph \( G \) with a non-negative length function on edges \( \text{len} : E \to \mathbb{R}_+ \). We will denote the pseudometric space associated with a graph \( G \) as \( (V, d_G) \), where \( d_G \) is the shortest path metric according to the edge lengths. Note that \( d_G(x, y) = 0 \) may occur even when \( x \neq y \), and also if \( G \) is disconnected, there will be pairs \( x, y \in V \) with \( d_G(x, y) = \infty \). We allow both possibilities throughout the paper. An important point is that all length functions in the paper are assumed to be reduced, i.e., they satisfy the property that for every \( e = (u, v) \in E \), \( \text{len}(e) = d_G(u, v) \).

Given a metric graph \( G \), we extend the length function to paths \( P \subseteq E \) by setting \( \text{len}(P) = \sum_{e \in P} \text{len}(e) \). For a pair of vertices \( a, b \in P \), we use the notation \( P[a, b] \) to denote the sub-path of \( P \) from \( a \) to \( b \). We recall that for a subset \( S \subseteq V \), \( G[S] \) represents the induced graph on \( S \). For a pair of subsets \( S, T \subseteq V \), we use the notations \( E(S, T) = \{(u, v) \in E : u \in S, v \in T\} \) and \( E(S) = E(S, S) \). For a vertex \( u \in V \), we write \( N(u) = \{v \in V : (u, v) \in E\} \).

**Graph minors.** If \( H \) and \( G \) are two graphs, one says that \( H \) is a minor of \( G \) if \( H \) can be obtained from \( G \) by a sequence of zero or more of the three operations: edge deletion, vertex deletion, and edge contraction. \( G \) is said to be \( H \)-minor-free if \( H \) is not a minor of \( G \). We refer to\[Lov06, Die05\] for a more extensive discussion of the vast graph minor theory.

Equivalently, \( H \) is a minor of \( G \) if there exists a collection of disjoint sets \( \{A_v \}_{v \in V(H)} \) with \( A_v \subseteq V(G) \) for each \( v \in V(H) \), such that each \( A_v \) is connected in \( G \), and there is an edge between \( A_u \) and \( A_v \) whenever \( (u, v) \in E(H) \). A metric space \( (X, d) \) is said to be \( H \)-minor-free if it is supported on some \( H \)-minor-free graph.

**Treewidth.** The notion of treewidth involves a representation of a graph as a tree, called a tree decomposition. More precisely, a tree decomposition of a graph \( G = (V, E) \) is a pair \( (T, \chi) \) in which \( T = (I, F) \) is a tree and \( \chi = \{\chi_i \ | \ i \in I\} \) is a family of subsets of \( V(G) \) such that (1) \( \bigcup_{i \in I} \chi_i = V \); (2) for each edge \( e = \{u, v\} \in E \), there exists an \( i \in I \) such that both \( u \) and \( v \) belong to \( \chi_i \); and (3) for all \( v \in V \), the set of nodes \( \{i \in I \ | \ v \in \chi_i\} \) forms a connected subtree of \( T \). To distinguish between vertices of the original graph \( G \) and vertices of \( T \) in the tree decomposition, we call vertices of \( T \) nodes and their corresponding \( \chi_i \)’s bags. The maximum size of a bag in \( \chi \) minus one is called the width of the tree decomposition. The treewidth of a graph \( G \) is the minimum width over all possible tree decompositions of \( G \).

**Pathwidth.** A tree decomposition is called a path decomposition if \( T = (I, F) \) is a path. The pathwidth of a graph \( G \) is the minimum width over all possible path decompositions of \( G \). We will use the following alternate characterization.
**Definition 1.8** (Linear composition sequence). Let $k$ be a positive integer. A sequence of pairs $(G_0, V_0), (G_1, V_1), \ldots, (G_t, V_t)$ is a linear width-$k$ composition sequence for $G$ if $G_t = G$, $G_0$ is a $k$-clique with vertex set $V_0$, and $(G_{i+1}, V_{i+1})$ arises from $(G_i, V_i)$ as follows: Attach a new vertex $v_{i+1}$ to all the vertices of $V_i$ and choose $V_{i+1} \subseteq V_i \cup \{v_{i+1}\}$ so that $|V_{i+1}| = k$. Observe that it is possible to have $V_{i+1} = V_i$. We further note that for any $j \in \{1, \ldots, t\}$, we have $V(G_j) = V_0 \cup \{v_1, \ldots, v_j\}$.

The following lemma is straightforward to prove.

**Lemma 1.9.** A graph has pathwidth-$k$ if and only if it is a subgraph of some graph possessing a linear width-$k$ composition sequence.

*Proof sketch.* A path decomposition of width $k$ can be obtained from a width-$k$ composition sequence $(G_0, V_0), \ldots, (G_t, V_t)$ by setting for every $i \in \{1, \ldots, t\}$, the $i$-th bag to be $V_{i-1} \cup \{v_i\}$. For the other direction, one can always assume that a pathwidth-$k$ graph admits a path decomposition of width $k$ such that every bag has size exactly $k+1$, and every two bags differ in exactly one vertex. This immediately yields a linear width-$k$ composition sequence. □

**Asymptotic notation.** For two expressions $E$ and $F$, we sometimes use the notation $E \preceq F$ to denote $E = O(F)$. We use $E \approx F$ to denote the conjunction of $E \preceq F$ and $E \succeq F$.

## 2 Warm-up: Embedding pathwidth-2 graphs into trees

In this section, we prove that Pathwidth$(2) \preceq$ Trees, as a warmup for the general case in Section 3. The pathwidth-2 case does not possess many of the difficulties of the general case; in particular, it does not require us to bound the stretch in multiple phases (for which we introduce a rank parameter in the next section). But it does show the importance of using an inflation factor to blowup small edges, in order for a certain geometric sum to converge.

Let $G = (V, E)$ be a metric graph of pathwidth 2. By Lemma 1.9 it suffices to give a probabilistic embedding for a graph $G$ possessing a linear width-2 composition sequence $(G_0, e_0), \ldots, (G_t, e_t)$, where $e_i$ plays the role of $V_i$ in Definition 1.8. We will inductively embed $G$ into a distribution over its spanning trees. First, we put $T_0 = e_0$. Now, let $T_i$ be a spanning tree of $G_i$, with $e_i \in E(T_i)$. We will produce a random spanning tree $T_{i+1}$ of $G_{i+1}$ with $e_{i+1} \in E(T_{i+1})$ as follows. Let $e_i = \{u, v\}$, and let $w^*$ be the newly attached vertex. We also add the edges $\{u, w^*\}$, and $\{v, w^*\}$, so the resulting graph is not a tree. We obtain a tree by randomly deleting either $\{u, w^*\}$, or $\{v, w^*\}$ as follows. Let $\tau = 12$; we refer to this constant as an “inflation factor.”

There are two cases.

1. If $e_i = e_{i+1}$, we delete $\{u, w^*\}$ with probability $\frac{\text{len}(u, w^*)}{\text{len}(u, w^*) + \text{len}(v, w^*)}$, and otherwise we delete $\{w^*, v\}$.

2. If $e_i \neq e_{i+1}$, assume (without loss of generality) that $e_{i+1} = \{v, w^*\}$. In that case, we delete $\{u, w^*\}$ with probability
   \[
   \min \left\{ \frac{\tau \text{len}(u, w^*)}{\text{len}(u, w^*) + \text{len}(u, v)}, 1 \right\},
   \]
   and otherwise we delete $\{u, v\}$.
It is easy to see that if $T_i$ was a spanning tree, then so is $T_{i+1}$. Furthermore, by construction $e_{i+1} \in E(T_{i+1})$. Let $T = T_i$ be the final tree, and set $T_i = T$ for $i > t$. It remains to bound the expected stretch in $T$.

For every edge $\{x, y\} \in E(G_i)$ and $i \geq 0$, define the value,

$$K_i^{x,y} = \max \left\{ \mathbb{E} \left[ \frac{d_T(x, y)}{d_{T_i}(x, y)} \mid T_i = \Gamma \right] : \mathbb{P}(T_i = \Gamma) > 0 \right\}.$$  

This is the maximum expected stretch between $x$ and $y$ incurred over all stages later than $i$, conditioned on the worst possible configuration for $T_i$.

For each $x \in V$, define $s(x) = -1$ for $x \in V(G_0)$, and otherwise it is the unique value $s \geq 0$ such that $x \in V(G_{s+1}) \setminus V(G_s)$. Also define $s(x, y) = \max(s(x), s(y))$. The next two lemmas form the core of our analysis.

**Lemma 2.1.** If $\{x, y\} \in E$ and $s(x, y) = i$, then

$$\mathbb{E} \left[ d_T(x, y) \right] \leq 3 \tau \cdot K_{i+1}^{x,y} \cdot \text{len}(x, y).$$

**Proof.** If $x, y \in V(G_0)$, then $K_0^{x,y} = 1$, and the claim is obvious. Otherwise, assume without loss of generality that $s(x) < s(y)$. In this case, it must be that $x \in e_i = \{u, v\}$ and $y = w^*$. Suppose that $x = u$.

If $e_{i+1} = e_i$, an elementary calculation based on case (1) of our algorithm yields,

$$\mathbb{E} \left[ \frac{d_{T_{i+1}}(u, w^*)}{\text{len}(u, w^*)} \mid T_i \right] \leq \frac{3 \text{len}(v, w^*) + \text{len}(u, w^*)}{\text{len}(v, w^*) + \text{len}(u, w^*)} \leq 3,$$

from which $\mathbb{E}[d_T(u, w^*)] \leq 3K_{i+1}^{u,w^*} \cdot \text{len}(u, w^*)$ immediately follows.

Similarly, if $e_{i+1} = \{v, w^*\}$, then the expected stretch is inflated by at most a factor of $\tau$, and therefore (3) again follows by a similar calculation. Finally, if $e_{i+1} = \{u, w^*\}$, then $\{u, w^*\} \in E(T_{i+1})$, and therefore $\mathbb{E}[d_T(u, w^*)] \leq K_{i+1}^{u,w^*} \cdot \text{len}(u, w^*)$.

**Lemma 2.2.** For any $\{x, y\} \in E(G_i)$, we have $K_i^{x,y} \leq \max\{3, K_{i+1}^{a,b}\}$ for some $\{a, b\} \in E(G_i)$.

**Proof.** Let $\Gamma$ be a tree on $V(G_i)$ which is a maximizer for $K_i^{x,y}$. Let $\Gamma_u$ and $\Gamma_v$ be the subtrees of $\Gamma \setminus e_i$ rooted at $u$ and $v$ respectively, where we recall that $e_i = \{u, v\}$. If $x$ and $y$ are both either in $\Gamma_u$, or in $\Gamma_v$, then $K_i^{x,y} = 1$, since $\Gamma_u$ and $\Gamma_v$ remain intact in the final tree $T$, conditioned on $T_i = \Gamma$.

So, it suffices to consider the case $x \in \Gamma_u$ and $y \in \Gamma_v$. Observe further that since the unique path between $x$ and $y$ in $\Gamma$ passes through $\{u, v\}$, and the $x$-$u$ and $y$-$v$ paths will both remain in $T$, we have

$$\mathbb{E} \left[ \frac{d_T(x, y)}{d_{T_i}(x, y)} \mid T_i = \Gamma \right] \leq \mathbb{E} \left[ \frac{d_T(u, v)}{d_{T_i}(u, v)} \mid T_i = \Gamma \right] \leq K_i^{u,v}.$$  

Thus to prove the lemma, it suffices to show that $K_i^{u,v} \leq \max\{3, K_{i+1}^{u,v}\}$. To this end, let $\Gamma$ be the maximizer for $K_i^{u,v}$, and suppose that $T_i = \Gamma$. If $e_{i+1} = e_i$, then the edge $\{u, v\}$ remains intact (i.e. $\{u, v\} \in E(T_{i+1})$), and therefore $K_i^{u,v} \leq K_{i+1}^{u,v}$. Assume now that $e_{i+1} \neq e_i$, which means that we are in case (2) of the algorithm. Assume further, without loss of generality, that $e_{i+1} = \{v, w^*\}$. Recall that either $\{u, v\}$ or $\{u, w^*\}$ is deleted.

\[ 7 \]
Let \( A = \text{len}(u, w^*) \), \( B = \text{len}(u, v) \), \( C = \text{len}(v, w^*) \). With probability \( p = \min\{1, \frac{\tau A}{A + B} \} \), the edge \( \{u, w^*\} \) is deleted, in which case \( d_T(u, v) = d_T(u, v) \). With probability \( 1 - p \), the edge \( \{u, v\} \) is deleted, and the new path between \( u \) and \( v \) in \( T_{i+1} \) is \( u \)-\( w^* \)-\( v \), so the distance between \( u \) and \( v \) is stretched to \( A + C \leq 2A + B \), and is eligible to be stretched by at most a factor \( K_{i+1}^{u,v} \) in the future.

Thus, if \( A \geq B/(\tau - 1) \), we have \( K_i^{u,v} = 1 \). We can therefore assume \( A < B/(\tau - 1) \). Thus we can bound,

\[
K_i^{u,v} \leq \frac{\tau A}{A + B} + K_{i+1}^{u,v} \left( 1 - \frac{\tau A}{A + B} \right) \frac{2A + B}{B}
\leq \frac{\tau A}{B} + K_{i+1}^{u,v} \left( 1 - \frac{\tau A}{2B} \right) \left( 1 + \frac{2A}{B} \right)
\leq \frac{\tau A}{B} + K_{i+1}^{u,v} \left( 1 - \frac{\tau A}{3B} \right),
\]

where we have used \( 1 - \frac{\tau A}{2B} + \frac{2A}{B} \leq 1 - \frac{\tau A}{3B} \) since \( \tau = 12 \). But now one sees that,

\[
K_i^{u,v} \leq \frac{\tau A}{B} (1 - K_{i+1}^{u,v}/3) + K_{i+1}^{u,v} \leq \max\{3, K_{i+1}^{u,v}\}.
\]

\[\square\]

Finally, the next lemma completes our analysis.

Lemma 2.3. For any \( x, y \in V \), we have \( \mathbb{E}[d_T(x, y)] \leq 9\tau \cdot d_G(x, y) \).

Proof. By the triangle inequality and linearity of expectation, it suffices to prove the lemma for edges \( \{x, y\} \in E \). We will prove the following by reverse induction on \( i \): For every \( \{x, y\} \in E \) and \( i \geq s(x, y) + 1 \), we have \( K_i^{x,y} \leq 3 \). Combining this with Lemma 2.1 will complete the proof.

The claim is trivial for \( i = t \) since \( K_t^{x,y} = 1 \) for all \( \{x, y\} \in E \). If \( t > i \geq s(x, y) + 1 \), then \( \{x, y\} \in E(G_i) \), and Lemma 2.2 immediately implies that \( K_i^{x,y} \leq \max\{3, K_{i+1}^{a,b}\} \) for some \( a, b \) with \( i + 1 \geq s(a, b) + 1 \). By induction, \( K_{i+1}^{a,b} \leq 3 \), hence \( K_i^{x,y} \leq 3 \) as well.

\[\square\]

3 Embedding pathwidth-\( k \) graphs into trees

We now turn to graphs of pathwidth \( k \) for some \( k \in \mathbb{N} \). Let \( G \) be such a graph. By Lemma 1.9, we may assume that \( G \) has a linear width-\( k \)-composition sequence, \( (G_0, V_0), \ldots, (G_t, V_t) \). For \( i \geq 1 \), we define \( \hat{V}_i = V_{i-1} \cup \{v_i\} \). Our algorithm for embedding \( G \) into a random tree proceeds inductively along the composition sequence. For each \( i \in \{1, \ldots, t\} \), we compute a subgraph \( H_i \) of \( G_i \), whose only non-trivial 2-connected component is a \( (k + 1) \)-clique on \( \hat{V}_i \) (see Figure 1). More specifically, \( H_1 \) is just a clique on \( \hat{V}_1 \). Given \( H_i \), we derive \( H_{i+1} \) by adding all the edges between \( v_{i+1} \) and \( V_i \), and removing all the edges, except for one, between \( V_i \) and the unique vertex in \( \hat{V}_i \setminus V_{i+1} \).

The main part of the algorithm involves determining which edge in \( (\hat{V}_i \setminus V_{i+1}) \times V_i \) we keep in \( H_{i+1} \). The high-level idea behind our approach is as follows. On one hand, we want to keep short edges so that the distance between \( \hat{V}_i \setminus V_{i+1} \) and \( V_i \) is small. On the other hand, keeping always the shortest edge leads to accumulation of the stretch for certain pairs (whose shortest-path keeps getting longer, through a sequence of “short” edges). We avoid this obstacle via a randomized process that assigns a rank to each edge, which intuitively means that edges of lower rank are more
Figure 1: The graph $H_i$.

likely to be deleted. More specifically, at each step $i$, we pick a random threshold $L$ and keep the highest ranked edge of length at most $L$, deleting the rest. We also update the ranks of the edges in the new graph appropriately.

Formally, let $\text{rank}_i : V(G) \times V(G) \to \mathbb{Z}_{\geq 0}$ be an arbitrary function, with $\text{rank}_1(u, v) = 0$, for each $u, v \in V(G)$. Let $E(\hat{V}_i) = (\hat{V}_i^2)$, i.e. the set of edges internal to $\hat{V}_i$. For $u, v \in V(H_i)$, let $P^u,v_i$ be the unique path between $u$ and $v$ in $H_i$ that contains at most one edge in $E(\hat{V}_i)$. Observe that $P^u,v_i$ is well-defined since $\hat{V}_i$ forms a clique. For an edge $e \in E(\hat{V}_i)$ we set

$$\text{edge-rank}_i(e) = \max_{u, v \in V(H_i) : e \in P^u,v_i} \text{rank}_i(u, v)$$

The randomized process for generating $H_{i+1}$ and $\text{rank}_{i+1}$ from $H_i$ and $\text{rank}_i$ is as follows. Let $\tau = 4k$ be our new “inflation factor.”

Let $w$ be the unique vertex in $\hat{V}_i \setminus V_{i+1}$, and enumerate $E(w, V_i) = \{e_1, e_2, \ldots, e_k\}$ so that $\text{len}(e_1) \leq \text{len}(e_2) \leq \cdots \leq \text{len}(e_k)$.

Now, let $\sigma_j_{j=1}^{k-1}$ be a family of independent $\{0,1\}$ random variables with

$$\mathbb{P}[\sigma_j = 1] = \min \left\{ 1, \tau \frac{\text{len}(e_j)}{\text{len}(e_{j+1})} \right\},$$

and define the set of eligible edges by

$$\mathcal{E} = \left\{ e_j : \prod_{i=1}^{j-1} \sigma_i = 1 \right\}.$$

In particular, $e_1 \in \mathcal{E}$ always. Let $e^* \in \mathcal{E}$ be any edge satisfying $\text{edge-rank}_i(e^*) = \max_{e \in \mathcal{E}} \text{edge-rank}_i(e)$.

Finally, we define $H_{i+1}$ as the graph with vertex set $V(G_{i+1})$ and edge set (see Figure 2),

$$E(H_{i+1}) = \{e^*\} \cup \{\{v_{i+1}, u\} : u \in V_i\} \cup (E(H_i) \setminus E(w, V_i)) .$$

We also define $\text{rank}_{i+1}$ as follows. For any $u, v \in V(G)$

$$\text{rank}_{i+1}(u, v) = \begin{cases} 
\text{rank}_i(u, v) & \text{if } E(P^u,v_i) \cap \mathcal{E} = \emptyset \\
\text{rank}_i(u, v) + 1 & \text{otherwise}.
\end{cases}$$
Intuitively, \( \text{rank}_i(u, v) \) counts how many times the path between \( u \) and \( v \) was under risk to be stretched until step \( i \).

It remains to analyze the expected stretch incurred by the above process. First, we observe that the maximum rank of an edge is \( O(k^2) \).

**Lemma 3.1.** For every \( i = 1, 2, \ldots, t \) and every edge \( e \in E(\hat{V}_i) \), edge-rank \( _i(e) \leq \binom{k+1}{2} \).

**Proof.** For each \( i = 1, 2, \ldots, t \), and each \( j = 1, 2, \ldots, \binom{k+1}{2} \), let \( R_{i,j} \) be the \( j \)-th largest edge-rank of the edges in \( E(V_i) \). That is, for each \( i = 1, 2, \ldots, t \), \( R_{i,1} \leq R_{i,2} \leq \cdots \leq R_{i,\binom{k+1}{2}} \).

We will prove by induction on \( i \) that for each \( i = 1, 2, \ldots, t \), for each \( 1 \leq j \leq \binom{k+1}{2} \), we have \( R_{i,j} \leq j \). For \( i = 1 \), all the ranks are equal to 0, and the assertion holds trivially.

Assume now that the assertion holds for \( i - 1 \). It is convenient to analyze the transition from step \( i - 1 \) to step \( i \) in three phases. We need to remove the edges in \( E(w, V_i) \) and add the edges in \( E(v_{i+1}, V_i) \), while updating the ranks accordingly. For notational simplicity, we assume that the rank of an edge that is removed is set to zero. Let \( e^* \) be the maximum-rank edge in \( E \). In the first phase, we set the rank of \( e^* \) to zero, and we increase the rank of all remaining edges in \( E \) by one. Clearly, the resulting edge ranks satisfy the inductive invariant.

In the second phase, for any edge \( e \in E(w, V_i) \), we update the rank of an edge \( e' = e'(e) \in E(\hat{V}_i) \cap E(\hat{V}_{i+1}) \) to be edge-rank \( (e') = \max\{\text{edge-rank}(e'), \text{edge-rank}(e)\} \), and we set the rank of \( e \) to zero. Clearly, after the second phase the ranks still satisfy the inductive invariant. Finally, in the third phase we transition from \( E(V_{i-1}) \) to \( E(V_i) \) by removing the edges in \( E(w, V_i) \), and by adding the edges in \( E(v_{i+1}, V_i) \). All the removed edges have at this point rank zero, and all new edges also have rank zero. Thus, the inductive invariant is satisfied. \( \square \)

For any \( i \in \{1, \ldots, t\} \), \( r \in \{0, \ldots, \binom{k+1}{2}\} \), and any edge \( \{u, v\} \in E(G_i) \), we put

\[
K_i^{u,v}(r) = \max \left\{ \mathbb{E} \left[ \frac{d_{H_i}(u, v)}{d_{H_i}(u, v)} \right] \mathbb{I}_{H_i = \Gamma, \text{rank}_i = \rho} : (\Gamma, \rho) \in \Omega_i(u, v; r) \right\},
\]

where we define

\[
\Omega_i(u, v; r) = \{ (\Gamma, \rho) : \mathbb{P}(H_i = \Gamma, \text{rank}_i = \rho) > 0 \text{ and } \rho(u, v) \geq r \}.
\]

In other words, \( K_i^{u,v}(r) \) is the maximum expected stretch for all stages after \( i \), conditioned on the worst possible configuration over subgraphs \( H_i \) and rank functions satisfying \( \text{rank}_i(u, v) \geq r \). We further define \( K_i^{u,v} \left( \binom{k+1}{2} + 1 \right) = 1 \).
For the next three lemmas and the corollary that follows, we fix an edge \( \{u, v\} \in E(G_t) \), and a number \( r \in \{0, \ldots, \binom{k+1}{2}\} \). Let \((\Gamma, \rho) \in \Omega_i(u, v; r)\) be a maximizer in \((\Pi)\), and write \( \mathbb{P}^i[\cdot] = \mathbb{P}[\cdot | H_i = \Gamma, \text{rank}_i = \rho] \) and \( \mathbb{E}^i[\cdot] = \mathbb{E}[\cdot | H_i = \Gamma, \text{rank}_i = \rho] \). A major point is that the follows calculations are oblivious to the conditioning, aside from the assumption that \( \text{rank}_i(u, v) \geq r \).

**Lemma 3.2.** Suppose that \( e_j \in E(P^i_{u,v}) \) for some \( j \in \{1, 2, \ldots, k\} \). Then,

\[
K^u,v_i(r) \leq \mathbb{P}^i[e_j \in \mathcal{E}] \left( 1 + 2 \frac{\mathbb{E}^i[\text{len}(e^*) | e_j \in \mathcal{E}]}{\text{len}(e_j)} \right) K^u,v_{i+1}(r+1) + \mathbb{P}^i[e_j \notin \mathcal{E}] \left( 1 + 2 \frac{\mathbb{E}^i[\text{len}(e^*) | e_j \notin \mathcal{E}]}{\text{len}(e_j)} \right) K^u,v_{i+1}(r)
\]

**Proof.** We have \( \frac{d_{H_{i+1}}(u,v)}{d_{H_{i}}(u,v)} \leq \frac{2\text{len}(e^*)+\text{len}(e_j)}{\text{len}(e_j)} \). There are two possibilities: (1) \( e_j \in \mathcal{E} \) occurs, and the rank of \( \{u, v\} \) is increased by 1, (2) \( e_j \notin \mathcal{E} \), and the rank of \( \{u, v\} \) either increases, or remains the same. This verifies the claimed inequality for \( r < \binom{k+1}{2} \).

Note that, by Lemma 3.1, \( \text{rank}_i(u, v) \leq \binom{k+1}{2} \). Thus the lemma holds true even for \( r = \binom{k+1}{2} \), in which case \( e_j \in \mathcal{E} \Rightarrow e_j = e^* \) (since the rank of the pair \( u, v \) cannot increase anymore). If this happens, then \( d_{H_{i}}(u,v) = d_{H_{i}}(u,v) \), again verifying the claimed inequality, since \( K^u,v_i \left( \binom{k+1}{2} + 1 \right) = 1 \) by definition.

**Lemma 3.3.** For any \( j \in [k] \), \( \mathbb{P}^i[e_j \in \mathcal{E}] \left( 1 + 2 \frac{\mathbb{E}^i[\text{len}(e^*) | e_j \in \mathcal{E}]}{\text{len}(e_j)} \right) \leq (4k)^{k} \text{len}(e_j) \text{len}(e_j) \).

**Proof.** We have

\[
\mathbb{P}^i[e_j \in \mathcal{E}] \left( 1 + 2 \frac{\mathbb{E}^i[\text{len}(e^*) | e_j \in \mathcal{E}]}{\text{len}(e_j)} \right) \\
\leq \tau^{-1} \frac{\text{len}(e_1)}{\text{len}(e_j)} \left( 1 + \frac{2}{\text{len}(e_j)} \sum_{h=1}^{k} \text{len}(e_h) \mathbb{P}^i[e^*_h = e_h | e_j \in \mathcal{E}] \right) \\
\leq \tau^{-1} \frac{\text{len}(e_1)}{\text{len}(e_j)} \left( 1 + \frac{2}{\text{len}(e_j)} \sum_{h=1}^{k} \text{len}(e_h) \mathbb{P}^i[e_h \in \mathcal{E} | e_j \in \mathcal{E}] \right) \\
\leq \tau^{-1} \frac{\text{len}(e_1)}{\text{len}(e_j)} \left( 1 + \frac{2}{\text{len}(e_j)} \left( \sum_{h=1}^{j} \text{len}(e_h) + \sum_{h=j+1}^{k} \text{len}(e_h) \frac{\text{len}(e_j)}{\text{len}(e_j)} \tau^{h-j} \right) \right) \\
\leq \tau^{-1} \frac{\text{len}(e_1)}{\text{len}(e_j)} \left( 1 + 2j + 2 \sum_{h=j+1}^{k} \tau^{h-j} \right) \\
\leq (2k + 1) \tau^{-1} \frac{\text{len}(e_1)}{\text{len}(e_j)} .
\]

**Lemma 3.4.** For any \( j \in [k] \), \( \mathbb{P}^i[e_j \notin \mathcal{E}] \left( 1 + 2 \frac{\mathbb{E}^i[\text{len}(e^*) | e_j \notin \mathcal{E}]}{\text{len}(e_j)} \right) \leq 1 - \frac{\text{len}(e_1)}{\text{len}(e_j)} .
\]
Proof. Let
\[ I = \{ h \in \{1, 2, \ldots, j - 1\} : \text{len}(e_{h+1}) > \tau \cdot \text{len}(e_h) \}. \]
Observe that if \( h \in \{1, 2, \ldots, j - 1\} \setminus I \), then whenever \( e_h \in \mathcal{E} \), we have also \( e_{h+1} \in \mathcal{E} \). For each \( h \in I \), let \( k_h = |I \cap \{1, 2, \ldots, h\}| \).

\[ \mathbb{P}^* \left[ e_j \notin \mathcal{E} \right] \leq \sum_{h=1}^{j-1} \mathbb{P}^* \left[ e_h \in \mathcal{E} \text{ and } e_{h+1} \notin \mathcal{E} \right] \left( 1 + \frac{2 \mathbb{E}^* \text{len}(e^*_h)}{\text{len}(e_j)} \right) \]
\[ = \sum_{h \in I} \mathbb{P}^* \left[ e_h \in \mathcal{E} \text{ and } e_{h+1} \notin \mathcal{E} \right] \left( 1 + \frac{2 \text{len}(e_h)}{\text{len}(e_j)} \right) \]
\[ \leq \sum_{h \in I} \tau^{k_h} \frac{1}{\text{len}(e_h)} \left( 1 - \frac{\text{len}(e_h)}{\text{len}(e_{h+1})} \right) \left( 1 + \frac{2 \text{len}(e_h)}{\text{len}(e_j)} \right) \]
\[ \leq \sum_{h \in I} \tau^{k_h} \frac{1}{\text{len}(e_h)} \left( 1 - \frac{\text{len}(e_h)}{\text{len}(e_{h+1})} \right) + \frac{\text{len}(e_1)}{\text{len}(e_j)} \sum_{h \in I} 2k^{k_h-1} \]
\[ \leq 1 - \tau |I| \frac{\text{len}(e_1)}{\text{len}(e_j)} + \frac{\text{len}(e_1)}{\text{len}(e_j)} (2k\tau |I| - 1) \]
\[ = 1 + \frac{\text{len}(e_1)}{\text{len}(e_j)} (2k\tau |I| - 1 - \tau |I|) \]
\[ \leq 1 - \frac{\text{len}(e_1)}{\text{len}(e_j)}. \]
\[ \square \]

**Corollary 3.5.** For every \( \{u, v\} \in E(G_i) \) and \( r \in \{0, \ldots, \binom{k+1}{2}\} \), we have

\[ K_{i,v}^{u,v}(r) \leq \max \left\{ (4k)^{k} K_{i+1}^{u,v}(r+1), K_{i+1}^{u,v}(r) \right\}. \]

**Proof.** Suppose that \( H_i = \Gamma \) and \( \text{rank}_i = \rho \). If \( E(P_i^{u,v}) \) is empty, then \( K_{i,v}^{u,v}(r) = 1 \) because the current \( u-v \) path in \( H_i \) will be preserved in \( H_{i+1} \). Otherwise, we have \( E(P_i^{u,v}) = \{ e_j \} \) for some \( j \in [k] \). Apply Lemmas 3.2, 3.3, and 3.4 to conclude that

\[ K_{i,v}^{u,v}(r) \leq (4k)^{k} \frac{\text{len}(e_1)}{\text{len}(e_j)} K_{i+1}^{u,v}(r+1) + \left( 1 - \frac{\text{len}(e_1)}{\text{len}(e_j)} \right) K_{i+1}^{u,v}(r) \]
\[ = \frac{\text{len}(e_1)}{\text{len}(e_j)} \left( (4k)^{k} K_{i+1}^{u,v}(r+1) - K_{i+1}^{u,v}(r) \right) + K_{i+1}^{u,v}(r) \]
\[ \leq \max \left\{ (4k)^{k} K_{i+1}^{u,v}(r+1), K_{i+1}^{u,v}(r) \right\}, \]
completing the proof. \[ \square \]

We can now state and prove our main theorem.

**Theorem 3.6.** For every \( k \geq 1 \), every metric graph of pathwidth \( k \) admits a stochastic \( D \)-embedding into a distribution over trees with \( D \leq O(k^{O(k^3)}) \).
Proof. Let $H_t$ be the random subgraph of $G$. Fix $\{u, v\} \in E(G)$, and suppose that $i_0$ is the smallest number for which $u, v \in V(G_{i_0})$. In this case, since $\{u, v\}$ is an edge, we have $d_{G_{i_0}}(u, v) = d_G(u, v)$, thus

$$\mathbb{E}[d_{H_t}(u, v)] \leq K_{i_0}^{u, v}(0) \cdot \text{len}(u, v).$$

Now applying Corollary 3.5 inductively immediately yields the bound,

$$K_{i_0}^{u, v}(0) \leq \left((4k)^k\right)^{(k+1)+1},$$

recalling that $K_{i_0}^{u, v}\left(\frac{k+1}{2} + 1\right) = 1$ for all $i$, and $K_{i_0}^{u, v}(r) = 1$ for all $r$.

Finally, observe that the only non-trivial 2-connected component of $H_t$ is a $(k + 1)$-clique on $V_t$. Replacing $V_t$ by a minimum spanning tree yields a tree $T$ with $d_T(u, v) \leq (k + 1) \cdot d_{H_t}(u, v)$. This completes the proof. □

4 Pathwidth $(k + 1) \not\rightarrow$ Pathwidth $(k)$

We now show that for any fixed $k \geq 1$, and for any $n \geq 1$, there exists an $n$-vertex graph of pathwidth $k + 1$ for which any stochastic $D$-embedding into a distribution over graphs of pathwidth $k$ has $D \geq \Omega(n^{2-k})$, where the $\Omega(\cdot)$ notation hides a multiplicative constant depending on $k$. In fact, our lower bound holds even for trees of pathwidth $k + 1$. We begin by giving two structural lemmas that allow us to decompose a tree of pathwidth $\ell$ into a path and a collection of trees of pathwidth at most $\ell - 1$.

Lemma 4.1. Let $G_1, G_2, G_3$ be connected graphs of pathwidth $k$ with disjoint vertex sets, and for $i \in [3]$, let $v_i \in V(G_i)$. Let $G$ be the graph obtained by introducing a new vertex $v^*$, and connecting it to $v_1, v_2$, and $v_3$. Formally, $V(G) = \{v^*\} \cup \bigcup_{i=1}^3 V(G_i)$, and $E(G) = \bigcup_{i=1}^3 E(G_i) \cup \{\{v^*, v_i\}\}$. Then $G$ has pathwidth $k + 1$.

Proof. It is easy to see that $G$ has pathwidth at most $k + 1$: For each $i \in [3]$ take a path decomposition of $G_i$ with bags $C_{i, 1}, \ldots, C_{i, \ell_i}$. For each $i \in [3], j \in [\ell_i]$, let $C'_{i, j} = C_{i, j} \cup \{v^*\}$. The bags $C'_{1, 1}, \ldots, C'_{1, \ell_1}, C'_{2, 1}, \ldots, C'_{2, \ell_2}, C'_{3, 1}, \ldots, C'_{3, \ell_3}$ induce a path decomposition of $G$ with width at most $k + 1$.

Assume now for the sake of contradiction that the pathwidth of $G$ is at most $k$. That is, there exists a path decomposition of $G$ with bags $C_1, \ldots, C_t$, such that: (i) for each $i \in [\ell], |C_i| \leq k + 1$, (ii) for each $\{u, v\} \in E(G)$ there exists $i \in [\ell]$ with $u, v \in C_i$, and (iii) for each $v \in V(G)$ there exists a subinterval $I \subset [\ell]$ such that $v \in C_i$ iff $i \in I$. For each $i \in [3]$, let $G'_i$ be the subgraph of $G$ induced by $V(G_i) \cup \{v^*\}$. Let also

$$A_i = \{j \in [\ell]: C_j \cap V(G'_i) \neq \emptyset\}.$$

Note that since $G'_i$ is connected, it follows that $A_i$ is a subinterval of $[\ell]$. Pick $i_1, i_2 \in [3]$, such that $1 \in A_{i_1}$, and $\ell \in A_{i_2}$. Note that we might have $i_1 = i_2$. Since $V(G'_{i_1}) \cap V(G'_{i_2}) \neq \emptyset$, we have that $A_{i_1} \cap A_{i_2} \neq \emptyset$. In particular, $A_{i_1} \cup A_{i_2} = [\ell]$. Therefore, each bag $C_i$ contains at least one vertex either from $G'_{i_1}$, or $G'_{i_2}$. Let $i_3$ be an element in $[3] \setminus \{i_1, i_2\}$. Removing $V(G'_{i_1}) \cup V(G'_{i_2})$ from all the bags $C_i$, we get a decomposition of $G \setminus (G'_{i_1} \cup G'_{i_2}) = G_{i_3}$ with width at most $k - 1$, a contradiction since $G_{i_3}$ has pathwidth $k$. □
Lemma 4.2. If $H$ is a minor of $G$, then the pathwidth of $H$ is at most the pathwidth of $G$.

Lemma 4.3. Let $T$ be a tree of pathwidth $\ell \geq 2$. Then, there exists a simple path $P$ in $T$ such that deleting the vertices of $P$ from $T$ leaves a forest with each tree having pathwidth at most $\ell - 1$.

Proof. For every $v \in V(T)$, let $\alpha(v)$ denote the number of connected components of $T \setminus \{v\}$ of pathwidth $\ell$. Observe that for any $v \in V(T)$, we have $\alpha(v) \leq 2$. To see that, assume for the sake of contradiction that there exists $v \in V(T)$, such that $T \setminus \{v\}$ contains connected components $C_1, C_2, C_3$, each of pathwidth at least $\ell$. Then, by Lemma 4.2 it follows that $T$ must have pathwidth $\ell + 1$, a contradiction.

First, observe that if there exists $v \in V(T)$ with $\alpha(v) = 0$, then the path containing only the single $v$ satisfies the assertion.

Next, we consider the case where for every $v \in V(T)$, $\alpha(v) = 1$. We construct a path $Q = x_1, \ldots, x_s$ as follows. We set $x_1$ to be an arbitrary leaf of $T$. Given $x_i$, let $y_i$ be the unique neighbor of $x_i$ in $T$, such that $y_i$ is contained in the unique connected component of $T \setminus \{x_i\}$ of pathwidth $\ell$. If there exists $j < i$, such that $x_j = y_i$, then we terminate the path $Q$ at $x_i$, and we set $s = i$. Otherwise, we set $x_{i+1} = y_i$, and continue at $x_{i+1}$. We now argue that $Q$ satisfies the assertion. For the sake of contradiction suppose that $T \setminus V(Q)$ contains a connected component $C$ of pathwidth $\ell$. The component $C$ must be attached to $Q$ via some edge $\{y, x_i\}$, with $y \in V(C)$. This implies however that the $y$ is chosen as $y_i$ when examining $x_i$, and therefore $y$ must be in $Q$, a contradiction.

Finally, it remains to consider the case where there exists at least one $v \in V(T)$, with $\alpha(v) = 2$. Let $X = \{v \in V(T) : \alpha(v) = 2\}$. Let $H = T[X]$ be the subgraph of $T$ induced on $X$. We first argue that $H$ is connected. To see this, let $x, y \in X$, and let $L$ be the unique path between $x$ and $y$ in $T$. Since $\alpha(x) = \alpha(y) = 2$, it follows that there exist connected components $C_x, C_y$ of $T \setminus V(L)$ with $C_x$ attached to $x$, and $C_y$ attached to $y$, such that both $C_x$ and $C_y$ have pathwidth $\ell$. Let $z \in V(L)$. It follows that there exist components $C'_x, C'_y$ of $T \setminus \{z\}$, such that $C_x \subseteq C'_x$, and $C_y \subseteq C'_y$, which implies that $\alpha(z) = 2$. Thus, $z \in X$. This implies that $L \subseteq H$, and therefore $H$ must be connected.

We next show that $H$ is a path. To see this suppose for the sake of contradiction that there exists $v \in V(H)$ with distinct neighbors $v_1, v_2, v_3 \in V(H)$. Since $\alpha(v_1) = \alpha(v_2) = \alpha(v_3) = 2$, it follows that there exist components $C_1, C_2, C_3$ of $T \setminus \{v, v_1, v_2, v_3\}$, with each $C_i$ attached to $v_i$, and such that each $C_i$ has pathwidth $\ell$, for all $i \in \{1, 2, 3\}$. Applying Lemma 4.1 we obtain that $T$ has pathwidth at least $\ell + 1$, a contradiction. Therefore, $H$ is a path.

Let $w_1, w_2$ be the two endpoints of the path $H$. Since $\alpha(w_1) = 2$, it follows that there exists a connected component of $C_{w_1}$ of $T \setminus V(H)$ of pathwidth $\ell$ which is attached to $w_1$. Similarly, there exists a connected component $C_{w_2}$ of $T \setminus V(H)$ of pathwidth $\ell$ which is attached to $w_2$. Let $w'_1, w'_2$ be the neighbors of $w_1$, and $w_2$ in $C_{w_1}$, and $C_{w_2}$ respectively. Let $H'$ be the path obtained by adding $w'_1$ to $H$, and $w'_2$ to $H$.

We will show that $Q = H'$ satisfies the assertion of the lemma. To that end, it remains to show that any connected component of $T \setminus V(H')$ has pathwidth at most $\ell - 1$. Let $C$ be a component of $T \setminus V(H')$, and suppose for the sake of contradiction that it has pathwidth $\ell$. Suppose first that $C$ is attached to a vertex $v \in V(H)$. Since $v \in V(H)$, it follows that $\alpha(v) = 2$. By applying Lemma 4.1 on the clusters $C, C_{w_1}$, and $C_{w_2}$, we obtain that $T$ contains a minor of pathwidth at least $\ell + 1$, which combined with Lemma 4.2 leads to a contradiction.

Finally, suppose that $C$ is attached to a vertex $w \in \{w'_1, w'_2\}$, and assume, without loss of generality, that $w = w'_1$. Then it follows that $T \setminus \{w\}$ contains at least two components of pathwidth
ℓ (one containing \( C \), and another containing \( C_{w_2} \)), and thus \( \alpha(w) = 2 \), a contradiction since \( w \notin X \).

This concludes the proof.

For each \( i \geq 1 \), let \( \Phi_i \) be the unit-weighted graph consisting of a vertex \( v \) connected to \( i \) disjoint paths of length \( i \). Observe that \( \Phi_i \) is a tree with \( i \) leaves. We consider \( \Phi_i \) as being rooted at the vertex \( v \).

For each \( i \geq 1 \), and for each \( m \geq 1 \), we define the graph \( \Psi_{i,m} \) as follows. For \( i = 1 \), we set \( \Psi_{1,m} = \Phi_{\lceil \sqrt{m} \rceil} \). For \( i \geq 2 \), let \( \Psi_{i,m} \) be the graph obtained by identifying the root of a copy of \( \Psi_{i-1,\sqrt{m}} \) with each leaf of \( \Phi_{\lceil \sqrt{m} \rceil} \). For \( \ell \leq \lceil \sqrt{m} \rceil \), let \( \Psi_{i,m,\ell} \) be the tree obtained from \( \Psi_{i,m} \) by deleting \( \lceil \sqrt{m} \rceil - \lceil \ell \rceil \) children of the root of \( \Psi_{i,m} \), along with everything underneath those children. In particular, \( \Psi_{i,m,\sqrt{m}} = \Psi_{i,m} \).

**Lemma 4.4.** For each \( i \geq 1 \) and \( m \geq 3^{2^i} \), \( \Psi_{i,m} \) has pathwidth \( i + 1 \).

**Proof.** Note that for \( m \geq 3^{2^i} \), \( \Psi_{i,m} \) contains, as a minor, a full ternary tree \( T \) of depth \( i \). Using Lemma 4.1 inductively shows that the pathwidth of the depth \( i \) ternary tree is \( i + 1 \), hence Lemma 4.2 implies that the pathwidth of \( \Psi_{i,m} \) is at least \( i + 1 \). It is also easy to check by hand that the pathwidth of \( \Psi_{i,m} \) is at most \( i + 1 \), for every \( m \geq 1 \).

Fix \( k \geq 1 \), and let \( G = \Psi_{k,m} \). By Lemma 4.4 for \( m \geq 3^{2^k} \), \( G \) has pathwidth \( k + 1 \). We will show that for \( m \) large enough, any stochastic \( c \)-embedding of \((V(G), d_G)\) into a distribution over metric graphs of pathwidth \( k \), has distortion \( c \geq \Omega(n^{2^{-k}}) \), where \( n = |V(G)| \).

Assume there exists a stochastic \( c \)-embedding of \((V(G), d_G)\) into a distribution over metric graphs of pathwidth \( k \). By composing this with the result of Theorem 3.6, we get a stochastic \( c' \)-embedding of \((V(G), d_G)\) into the family of metrics supported on \( \text{Pathwidth}(k) \cap \text{Trees} \), with \( c' = O(c) \) (where the \( O(\cdot) \) notation hides a constant depending on the fixed parameter \( k \)).

By averaging, there exists a metric tree \( T \) of pathwidth \( k \) and a single non-contractive mapping \( f : V(G) \to V(T) \) which satisfies,

\[
\frac{1}{|E(G)|} \sum_{\{u,v\} \in E(G)} d_T(f(u), f(v)) \leq c'.
\]

Thus it suffices to prove a lower bound on this quantity. In fact we will prove a somewhat stronger statement; we will give a lower bound on the average stretch of any non-contractive embedding of \( \Psi_{k,m,\sqrt{m}/2} \). We first prove an auxiliary lemma.
Lemma 4.5. Let $S$ be an unweighted tree with $r \in V(S)$, and let $L \geq 0$. Let $S_1, \ldots, S_k$ be vertex-disjoint subtrees of $S$ such that for each $i \in [k]$, $S_i$ is attached to $r$ via a path $Q_i$ of length at least $L$, and for each $i \neq j \in [k]$, the paths $Q_i$ and $Q_j$ intersect only at $r$. Let $g : V(S) \to V(T)$ be a non-contractive embedding of $S$ into a metric tree $T$, and let $P$ be a simple path in $T$. If $I = \{i \in [k] : d_T(g(S_i), P) < L/2\}$, then

$$
\sum_{\{u,v\} \in E(S)} d_T(g(u), g(v)) \geq \frac{|I|^2 L}{16}.
$$

Proof. For each $i \in I$, let $z_i = \arg \min_{v \in P} d_T(v, g(S_i))$, and

$$
B_i = B_T(z_i, L/2) \cap V(P) = \{x \in P : d_T(z_i, x) \leq L/2\}.
$$

Since $g$ is non-contractive, we have that for each $i, j \in I$ with $i \neq j$, $d_T(g(S_i), g(S_j)) \geq 2L$, and therefore

$$
d_T(z_i, z_j) \geq d_T(g(S_i), g(S_j)) - d_T(g(S_i), z_i) - d_T(g(S_j), z_j) = 2L - d_T(S_i, P) - d_T(S_j, P) > L,
$$

which implies $B_i \cap B_j = \emptyset$.

By reordering, we assume that $I = \{1, 2, \ldots, |I|\}$, and that for each $i, j \in I$ with $i < j$, $B_i$ appears to the left of $B_j$ in $P$, after fixing some orientation of $P$. Furthermore, by choosing the proper orientation, we may assume that there is a vertex $u_0 \in P$ such that $u_0$ is contained in, or appears to the left of $B_{\lfloor |I|/2 \rfloor}$ in $P$, and $g(r)$ and $u_0$ are in the same subtree of $T \setminus E(P)$.

For each $i \in \{1, \ldots, |I|\}$, let $w_i = \arg \min_{v \in V(S_i)} d_S(v, r)$. It follows that for each $i \in \left\{\lfloor |I|/2 \rfloor + 1, \ldots, |I|\right\}$,

$$
d_T(g(r), g(w_i)) \geq (i - \lfloor |I|/2 \rfloor) L.
$$

Furthermore, for every $i \in [k]$, clearly $d_T(g(r), g(w_i)) \geq L$ by non-contractiveness. Therefore,

$$
\sum_{\{u,v\} \in E(S)} d_T(g(u), g(v)) \geq \sum_{i \in \{1, \ldots, |I|\}} \sum_{\{u,v\} \in E(Q_i)} d_T(g(u), g(v)) \\
\geq \sum_{i \in \{1, \ldots, |I|\}} d_T(g(r), g(w_i)) \\
\geq \left\lceil \frac{|I|}{2} \right\rceil L + \sum_{i \in \left\{\lfloor |I|/2 \rfloor + 1, \ldots, |I|\right\}} \left(i - \left\lfloor \frac{|I|}{2} \right\rfloor\right) L > \frac{|I|^2 L}{16}.
$$

The proof of the lower bound proceeds by induction on $k$. We first prove the base case for embedding into trees of pathwidth one.

Lemma 4.6. Let $g : V(\Psi_1, m, \sqrt{m/2}) \to V(T)$ be a non-contracting embedding into a metric tree $T$ of pathwidth one. Then,

$$
\frac{1}{|E(\Psi_1, m, \sqrt{m/2})|} \sum_{\{u,v\} \in E(\Psi_1, m, \sqrt{m/2})} d_T(g(u), g(v)) \geq \frac{\sqrt{m}}{216}.
$$
Proof. Since the tree $T$ has pathwidth one, it consists of a path $P = \{v_1, \ldots, v_t\}$, and a collection of vertex-disjoint stars $T_1, \ldots, T_t$, with each $T_i$ being rooted at $v_i$. Note that $T_i$ might contain only the vertex $v_i$.

Recall that $\Psi_{1,m,\sqrt{m}/2}$ consists of $\lceil \sqrt{m}/2 \rceil$ disjoint paths $Q_1, \ldots, Q_{\lceil \sqrt{m}/2 \rceil}$, with

$$Q_i = \{r, q_{i,1}, \ldots, q_{i,\lceil \sqrt{m} \rceil}\},$$

where $r$ is the root of $\Psi_{1,m,\sqrt{m}/2}$. For each $i \in [[\sqrt{m}/2]]$ let $Q_i'$ be the subpath of $Q_i$ of length $\lfloor \sqrt{m}/2 \rfloor$ with $Q_i' = \{q_{i,\lfloor \sqrt{m}/2 \rfloor}, \ldots, q_{i,\lceil \sqrt{m} \rceil}\}$.

Let $I_1 = \{i \in [[\sqrt{m}/2]] : d_T(g(Q_i'), P) \geq \sqrt{m}/4\}$, and let $I_2 = [[\sqrt{m}/2]] \setminus I_1$. By Lemma 4.5,

$$\sum_{\{u, v\} \in E(\Psi_{1,m,\sqrt{m}/2})} d_T(g(u), g(v)) \geq \frac{|I_2|^2 \sqrt{m}}{32}.$$

Since $|E(\Psi_{1,m})| \leq 2m$, we are done if $|I_2| \geq \sqrt{m}/4$.

It remains to consider the case $|I_1| \geq \lfloor \sqrt{m}/4 \rfloor$. Observe that for each $i \in I_1$, all the edges of $Q_i'$ have their endpoints mapped to distinct leaves of the stars $T_1, \ldots, T_t$, with the edge adjacent to each such leaf having length at least $\sqrt{m}/8$, by non-contractiveness of $g$. Therefore, each edge of such a $Q_i'$ is stretched by a factor of $\sqrt{m}/4$ in $T$. In other words,

$$\frac{1}{|E(\Psi_{1,m,\sqrt{m}/2})|} \sum_{\{u, v\} \in E(\Psi_{1,m,\sqrt{m}/2})} d_T(g(u), g(v)) \geq \frac{1}{2m} \cdot |I_1| \cdot \sqrt{m}/4$$

$$= \frac{\sqrt{m}}{8} \cdot \frac{\sqrt{m}}{2} \geq \frac{\sqrt{m}}{64},$$

with the latter bound holding for $m \geq 4$. Observe that the LHS is always at least 1, yielding the desired result for $m \leq 4$ as well, and completing the proof. \hfill $\Box$

We are now ready to prove the main inductive step.

**Lemma 4.7.** Let $k \geq 1$, and let $g : V(\Psi_{k,m,\sqrt{m}/2}) \rightarrow V(T)$ be a non-contractive embedding of $\Psi_{k,m,\sqrt{m}/2}$ into a metric tree $T$ of pathwidth $k$. Then, for all $m = (2a)^{2^k}$, with $a \in \mathbb{N}$, we have

$$\frac{1}{|E(\Psi_{k,m,\sqrt{m}/2})|} \sum_{\{u, v\} \in E(\Psi_{k,m,\sqrt{m}/2})} d_T(g(u), g(v)) \geq \frac{m^{2-k}}{2^{8+2k} \cdot k}.$$

**Proof.** We proceed by induction on $k$. The base case $k = 1$ is given by Lemma 4.6, so we can assume that $k \geq 2$, and that the assertion is true for $k - 1$.

Since the tree $T$ has pathwidth $k \geq 2$, by Lemma 4.3 it follows that it consists of a path $P$, and a collection of trees $T_1, \ldots, T_t$ of pathwidth at most $k - 1$, with each $T_i$ being rooted at some vertex $v_i$, and $v_i$ being attached to $P$ via an edge. Recall that $\Psi_{k,m,\sqrt{m}/2}$ consists of a root $r$ and $\sqrt{m}/2$ subtrees $Q_1, \ldots, Q_{\sqrt{m}/2}$, with each $Q_i$ having a copy $Q_i'$ of $\Psi_{k-1,\sqrt{m}}$ that is connected to $r$ via a path of length $\sqrt{m}$.
Let $I_1 = \{ i \in [\sqrt{m}/2] : d_T(g(Q'_i), P) \geq \sqrt{m}/8 \}$, and let $I_2 = [\sqrt{m}/2] \setminus I_1$. By Lemma 4.5,

$$\sum_{\{u,v\} \in E(\Psi_{k,m,\sqrt{m}/2})} d_T(g(u), g(v)) \geq \frac{|I_2|^2 \sqrt{m}}{16}.$$  

Since $|E(\Psi_{k,m})| \leq km$, this yields the desired result for $|I_2| \geq \sqrt{m}/4$.

It remains to consider the case $|I_1| \geq \sqrt{m}/4$. Let $I_{1,1}$ be the subset of $I_1$ containing all indices $i \in I_1$ such that for some $j \in [t]$, $T_j$ contains the image of a copy of $\Psi_{k-1,m^{1/2},m^{3/4}}$ from $Q'_i$. Let also $I_{1,2} = I_1 \setminus I_{1,1}$.

By the induction hypothesis it follows that for any $i \in I_{1,1}$,

$$\sum_{\{u,v\} \in E(Q'_i)} d_T(g(u), g(v)) \geq m^{1/2} \cdot (k - 1) \cdot \frac{m^{2^{1-k}}}{2^{6+2k}(k-1)}. \tag{5}$$

Consider now $i \in I_{1,2}$. Let $r_i$ be the root of $Q'_i$ and let $W_{i,1}, \ldots, W_{i,m^{1/4}}$ be the copies of $\Psi_{k-1,m^{1/2},1}$ in $Q'_i$, intersecting only at $r_i$. By the definition of $I_{1,2}$ we have that for any $J \subset [m^{1/4}]$ with $|J| = m^{1/4}/2$, and for any $i' \in [t]$, $\bigcup_{j \in J} g(W_{i,j}) \not\subseteq T_{i'}$. Assume that the image of $r_i$ is contained in $T_\tau$, for some $\tau \in [t]$. It follows that there exists $R \subset [m^{1/4}]$, with $|R| \geq m^{1/4}/2$, such that for each $j \in R$, the image of $W_{i,j}$ intersects some tree $T_{\sigma_j}$, with $\sigma_j \neq \tau$. Since $r_i \in V(W_{i,j})$ it follows that there exists an edge $e_{i,j} \in E(W_{i,j}) \cup E(Z_{i,j})$ that is stretched by a factor of at least $m^{1/2}/4$. It follows that for any $i \in I_{1,2}$,

$$\sum_{\{u,v\} \in E(Q'_i)} d_T(g(u), g(v)) \geq \frac{m^{1/4}}{2} \cdot \frac{m^{1/2}}{4}. \tag{6}$$

Combining (5) and (6) we obtain

$$\frac{1}{|E(\Psi_{k,m,\sqrt{m}/2})|} \sum_{\{u,v\} \in E(\Psi_{k,m,\sqrt{m}/2})} d_T(g(u), g(v)) \geq \frac{1}{k \cdot m} \cdot |I_1| \cdot m^{1/2} \cdot (k - 1) \cdot \frac{m^{2^{1-k}}}{2^{6+2k}(k-1)}$$

$$> \frac{m^{2-k}}{2^{8+2k} \cdot k},$$

as desired. \qedhere

We have proved the following theorem.

**Theorem 4.8.** For any fixed $k \geq 1$, and for any $n \geq 1$, there exists an $n$-vertex tree $G$ of pathwidth $k+1$, such that any stochastic $D$-embedding of $G$ into a distribution over metric graphs of pathwidth $k$, has $D \geq \Omega(n^{2-k})$. In particular, Pathwidth$(k+1) \cap$ Trees $\not\approx$ Pathwidth$(k)$.
