Isogeometric Analysis for Linear and Nonlinear Cantilever in CAD

Mian Zhou
Department of Machine and Process Engineering, Technical University Kaiserslautern, Kaiserslautern 67655, Germany

Abstract: A novel method for the mechanical simulation of linear and nonlinear Timoshenko-beams has been presented. The beam strains are based on a kinematic assumption where the shear deformation and rotational are considered. Applying the isoparametric concept the kinematic quantities are approximated using NURBS (non-uniform Rational B-spline) functions. This numerical simulation can be called as isogeometric analysis, which can improve the efficiency in CAD (computer aided design). Furthermore, an efficient Code has been developed and the results for two numerical applications are given in the end.

Key words: Isogeometric analysis, NURBS basis functions, Timoshenko-beams, finite element formulation.

1. Introduction

Three-dimensional beam-like structures can be found frequently in man-made structures, like helicopter blades, robot arms or rotor blades. Due to the shear deformation and rotational bending effects, Stephen Timoshenko introduced the so-called Timoshenko-beam theory early in the 20th century to describe the behavior of this beams [1]. According to the Timoshenko-beam theory, several authors developed finite element formulations for three-dimensional beams using a Lagrangian formulation, see Bathe and Bolourchi [2]. The problem of this formulation is imprecise approaches of the geometry of the three-dimensional beam in CAD and analysis. Furthermore this kind of formulation increases the computational cost.

Currently we can solve this problem with the help of the isogeometric analysis, which is developed by J. Austin Cottrell and Thomas J. R. Hughes in 2005. The isogeometric analysis is the bridge between integrating FEA (finite element analysis) and NURBS (non-uniform rational B-spline) based CAD (computer aided design). The basic idea of isogeometric analysis is to use the same geometry description for design and analysis. Also there are many computational technologies that may be used in isogeometric analysis, e.g. NURBS or T-splines. Due to the convenience of the free form surface modeling the NURBS-functions are chosen as usual. The isogeometric analysis has been provided by many authors (e.g. Morganti [3]), that the isogeometric analysis can increase the accuracy and reduce the computational cost.

In this paper the isogeometric analysis for linear and nonlinear cantilever is discussed. A cantilever is a basic structural element in industrial design, e.g. beam or plate, which can be considered as three-dimensional beam. Furthermore the author developed an efficient Code in order to calculate the deflection of the cantilever under different loads.

2. Isogeometric Parameterization of the Beam Model

2.1 NURBS Basis Functions and Curves

In Computational Engineering B-spline and NURBS are commonly used for describing curves and surfaces because of its great flexibility and precision. Here we briefly discuss the definitions and properties of NURBS, which can be found in Refs. [4, 5].

Corresponding author: Mian Zhou, Master of Science, research field: computational engineering.
Before talking about the B-spline we define a knot vector \( \Xi = \{\xi_1, \xi_2, ..., \xi_{n+p+1}\} \), which is non-decreasing sequence of knots \( \xi_i \in \mathbb{R} \) on the parameter space. \( i \) is the knot index from 1 to \( n + p + 1 \), where \( p \) is the polynomial order and \( n \) is the number of basis functions. If the knots are divided equidistantly \( (\xi_i - \xi_{i+1} = \text{constant}) \) into parameter space, the knot vector is defined as uniform, otherwise it is called non-uniform. Usually we discuss the open knot vector, which the first and last knot values repeat \( p + 1 \) times

\[
\Xi = \underbrace{\{\xi_1, \xi_2, ..., \xi_{p+1}, ..., \xi_{n-1}, \xi_n, \xi_{n+1}, \xi_{n+2}, ..., \xi_{n+p+1}\}}_{p+1},
\]

The B-spline basis functions \( N_{i,p}(\xi) \) are defined by the Cox-de Boor recursion formula (Cox, 1971; de Boor, 1972). If \( p = 0 \):

\[
N_{i,0}(\xi) = \begin{cases} 1, & \xi_i \leq \xi < \xi_{i+1} \\ 0, & \text{else} \end{cases}
\]

If \( p > 0 \):

\[
N_{i,p}(\xi) = \frac{\xi - \xi_i}{\xi_{i+p} - \xi_i} N_{i,p-1}(\xi) + \frac{\xi_{i+p+1} - \xi}{\xi_{i+p+1} - \xi_{i+1}} N_{i+1,p-1}(\xi)
\]

Caution: The quotient \( 0/0 \) is defined to be 0.

Furthermore we introduce some important properties for B-spline, which are usually used.

- Partition of unity: \( \sum_{i=0}^{n} N_{i,p}(\xi) = 1 \), for all \( \xi \);
- Nonnegativity: \( N_{i,p}(\xi) \geq 0, \forall \xi \);
- Derivatives: Each \( p \)th order function has \( p - 1 \) continuous derivatives across the boundaries.

Next we introduce vector-valued coefficients \( B_i \), which are called control points. With help of those we can build a B-spline curve easily.

\[
C(\xi) = \sum_{i=1}^{n} N_{i,p}(\xi) B_i
\]

The difference between B-spline basis functions \( N_{i,p} \) and NURBS basis functions \( R_{i,p} \) is additional weight \( \omega_i \), which is ever positive.

\[
R_{i,p} = \frac{N_{i,p}(\xi) \omega_i}{\sum_{j=1}^{n} N_{j,p}(\xi) \omega_j}
\]

Analog a NURBS curve can be written as

\[
C(\xi) = \sum_{i=1}^{n} R_{i,p}(\xi) B_i.
\]

In the end some important properties of spline curves on open knot vectors will be mentioned.

- Convex hull property: The curve is completely contained in its control polygon.
- Locality: \( N_{i,p}(\xi) = 0, \text{if } \xi \notin [\xi_i, \xi_{i+p+1}] \);
- Interpolation of start and end points: \( C(\xi_1) = C_1, \) \( C(\xi_m) = C_n \).
- Affine transformations of the curve can be performed directly on its control points.

2.2 Parameterization of Linear Timoshenko-Beam

One of the simplest and most important design elements is the beam, which has a ready application in engineering work. There are two assumptions of beam, which should be mentioned. The one is “plane sections remain plane”, which means, the plane cross-sections of the undeformed beam remain plane to the deflection curve of the deformed beam. Another is that, the deformation of the beam in the vertical direction should be neglected. In this paper we discuss the Timoshenko-beams, which occur in different areas of engineering practice.

According to the technical mechanics [6] we can write the following basic equations easily.

\[
\begin{align*}
\omega &= \omega(x)u(x, z) = -z\beta(y)\gamma x = \frac{\partial \omega}{\partial x} + \frac{\partial u}{\partial z} \varepsilon \\
\frac{\partial u}{\partial x} &= -z\beta' \gamma = \omega' - \beta
\end{align*}
\]

For linear Timoshenko-beam the transverse force \( Q \) and the bending moment \( M \) can be written as:

\[
Q = \int \tau dA = G\bar{A}\gamma M = \int z\sigma dA = -E\bar{I} \beta'.
\]

Here \( \bar{A} \) is the cross-section due to the shear stress. Furthermore the deflection and the Twist can be
written as $\omega$ and $\beta$. Now the potential of internal and external forces can be presented as following:

$$
\Pi_1(\omega, \beta) = \int_0^l (M \beta' + Qy) dx \Pi_0(\omega, \beta)
$$

$$
= - \int_0^l q\omega dx
$$

(8)

According to the principle of virtual work the total potential is zero.

$$
\delta(\Pi_1(\omega, \beta) + \Pi_0(\omega, \beta)) = 0
$$

2.3 Parameterization of Nonlinear Timoshenko-Beam

The finite element formulation of nonlinear Timoshenko-beam is different from the linear situation. First of all we introduce an orthogonal basis system $A_i$ of reference configuration and $a_i$ of current configuration. Therefore we can describe the axis of the beam along $A_1$ with the arc-length parameter $S = \xi_i \in [0, L]$. The cross-sections of the beam are described by the local coordinates $\{\xi_2, \xi_3\}$, which is shown in Fig. 1.

Hence, the position vectors of the undeformed and deformed cross-sections can be expressed as

$$
X(\xi_2, \xi_3, S) = X_0(S) + \xi_2 A_2(S) + \xi_3 A_3(S)
$$

\[\text{(8)}\]

$$
x(\xi_2, \xi_3, S, t) = x_0(S, t) + \xi_2 a_2(S, t) + \xi_3 a_3(S, t)
$$

\[\text{(17)}\]

$A_i$ and $a_i$ are the vectors, which follow from the orthogonal transformations ($A_i = R_i e_i$, $a_i = R_i e_i$). The matrix $R$ follows from the so-called Rodrigues formula. Applying the following well-known Euler-Lagrange equilibrium equations of a three-dimensional beam

$$
f' + \ddot{n} = 0
$$

\[\text{(9)}\]

$$
\dot{m} + x_0 \times \dot{f} + \ddot{m} = 0
$$

\[\text{(10)}\]

We obtain the virtual work that can be expressed as follows

$$
\mathcal{G}(\nu, \delta \nu) = - \int_x ((f' + \ddot{n}) \cdot \delta x_0 + (m' + x_0 \times \dot{f} + \ddot{m}) \cdot \delta \omega dS = 0.
$$

\[\text{(11)}\]

Now we introduce two strain measures $\epsilon$ and $\kappa$, which have been proposed by Reissner [7].

$$
\epsilon = R^T x_0 - R_i^T X_i \kappa = R^T \theta - R_i^T \theta_i
$$

\[\text{(12)}\]

The variations of those strain measures are given as follows:

$$
\delta \epsilon = R^T \delta x_0 + \delta R^T x_0 = R^T (\delta x_0 - \delta \omega \times x_0')
$$

\[\text{(13)}\]

$$
\delta \kappa = R^T \delta \theta + \delta R^T \theta = R^T \delta \omega'
$$

\[\text{(14)}\]

A proof of Eq. (23) is given in Ref. [8]. With $f = RF$ and $m = RM$ the virtual work can be
reformulated using the relationship \( dV = dAdS \). This yields

\[
\mathcal{G}(v, \delta v) = \int_s \left( \delta \hat{E}^T \hat{S} - \hat{n} \cdot \delta x_q \right) dS
\]

\[
= \int_{\Omega_0} S \cdot \delta EdV
- \int_{\Omega_0} \rho_0 \overline{b} \cdot \delta udV
- \int_{\partial \Omega_0} \hat{t} \cdot \delta ud\Gamma
\]

with \( x_q = x_0 + a_q \). The load \( \overline{n} \) in this paper is the sum of the volume forces \( \rho_0 \overline{b} \) and the surface loads \( \hat{t} \). The vector of stress resultants \( \hat{S} \) can be expressed as following:

\[
\hat{S} = \begin{bmatrix} F^1 & F^2 & F^3 \\ M^1 & M^2 & M^3 \end{bmatrix}
\]

\[
\begin{array}{c}
\text{normal force} \\
\text{shear force} \\
\text{tensile force} \\
\text{shear force} \\
\text{bending moment} \\
\text{bending moment} \\
\end{array}
\]

By using the directional derivative we can easily linearize the weak form of Eq. (24). This yields

\[
D\mathcal{G}(v, \delta v) \cdot \Delta v = \int_s \left( \delta \hat{E}^T \hat{D} \Delta \hat{E} + \Delta \delta \hat{E}^T \hat{S} \right) dS
\]

\[- \int_s \overline{q} \cdot \Delta \delta x_q dS
\]

where, \( v = [u \ R]^T \) describes the independent kinematic quantities of the beam. In parallel with linear situation we can derive the discretization of the following kinematic variables by using the NURBS shape functions.

\[
X_0 = \sum_{l=1}^{\text{n_en}} N_l(\xi) x_l = \sum_{l=1}^{\text{n_en}} N_l(\xi)(X_l + u_l)
\]

Thus, the virtual beam strains \( \delta \hat{E} \) can be written as follows:

\[
\delta \hat{E} = \sum_{l=1}^{\text{n_en}} B_l \delta v_l B_l
\]

\[
= \begin{bmatrix} N_l R_l^T & N_l B_{el}^T \\
0 & N_l B_{el}^T \end{bmatrix}
\]

where, the matrix \( B_{el} \) are defined as follows:

\[
B_{el} := \begin{bmatrix} O_{3l}(a_3) & O_{3l}(a_1) & O_{1l}(a_2) \end{bmatrix} B_{el}
\]

\[
= \begin{bmatrix} O_{3l}(a_3) & O_{3l}(a_1) & O_{2l}(a_1) \end{bmatrix}
\]

Subsequently we insert the finite element interpolation into the linearized form (26) and we obtain

\[
L[\mathcal{G}(v, \delta v)] = \bigcup_{e=1}^{\text{n_en}} \sum_{l=1}^{\text{n_en}} \sum_{k=1}^{\text{n_en}} \delta v_l^e \left( f_l^T + K_{el}^l \Delta v_k \right)
\]

Hence the matrix \( K_{el}^l \) describes the tangential stiffness matrix of element \( e \) of the nodes \( l \) and \( K \). The vector \( f_l^e \) is the sum of the internal and external nodal forces of the node \( l \). Considering Eqs. (26)-(29) we obtain
\[ K_{IK}^n = \int_s (B_i^T \hat{D} B_K + G_{IK} + P_{IK}) dS f_i \]
\[ = \int_s (B_i^T \hat{S} - N_i \bar{q}) dS \]

with \( \bar{q} = [\bar{n}, \bar{m}]^T \). In this paper the matrix \( \hat{D} \) denotes the elasticity matrix, which can be described as follows:
\[ \hat{D} = diag[EA, GA, GA, GI_T, EI_{33}, EI_{22}] \] (16)

The matrix \( G_{IK} \) and \( P_{IK} \) come from the linearized virtual strains and external loading. The detail of those matrixes can be found in Ref. [9].

3. Numerical Applications

3.1 Cantilever Timoshenko Beam

In order to test the reliability of the Code we present two examples with finite deformations and elastic material behavior in this section. The first example is a cantilever Timoshenko-beam with a concentrated load acting downward at the free end, which is illustrated in Fig. 2.

The geometrical and material data of this Timoshenko-beam are given as follows:
\[ \ell = 20 \varepsilon = 1 \nu = 1 \cdot 10^7 \rho = 0 \] (17)

The maximal deflection of this beam can be expressed as follow:
\[ \omega_{max} = \frac{FL^3}{3EI} + \frac{Fl}{GA} \omega_x \] (34)

Now, we simulate the cantilever beam in linear and nonlinear situation with increasing load, respectively. The results are presented in Table 1.

The differences between the both beams are illustrated in Fig. 3. The deflections of nonlinear beam are always smaller than the deflections of linear beam. Those results match with our common sense.

---

**Table 1  Results: deflections of linear and nonlinear Timoshenko-beam.**

| Force | Linear beam | Nonlinear beam | Difference |
|-------|-------------|----------------|------------|
| 100   | 3.21E-1     | 3.20E-1        | 1.00E-3    |
| 150   | 4.82E-1     | 4.80E-1        | 1.90E-3    |
| 200   | 6.42E-1     | 6.39E-1        | 3.40E-3    |
| 250   | 8.03E-1     | 7.97E-1        | 5.70E-3    |
| 300   | 9.64E-1     | 9.55E-1        | 8.90E-3    |
| 350   | 1.12E+0     | 1.11E+0        | 1.32E-2    |
| 400   | 1.28E+0     | 1.27E+0        | 1.87E-2    |
| 450   | 1.45E+0     | 1.42E+0        | 2.56E-2    |
| 500   | 1.61E+0     | 1.57E+0        | 3.40E-2    |
| 550   | 1.77E+0     | 1.72E+0        | 4.41E-2    |
| 600   | 1.93E+0     | 1.87E+0        | 5.60E-2    |
| 650   | 2.09E+0     | 2.02E+0        | 6.99E-2    |
| 700   | 2.25E+0     | 2.16E+0        | 8.57E-2    |
Eq. (35) can be found in Ref. [10]. The numerical solutions are reported in Table 2, which have no difference from the analytical solutions.

4. Conclusions

In this paper an efficient and robust isogeometric linear and nonlinear cantilever formulation has been presented. The main contribution of this work is programming an efficient code in order to analyze the deflection of the cantilever. Two numerical examples by using the isogeometric analysis have been discussed. The results have been calculated by computer and presented in the end. Because of the distinguished characters of the NURBS functions the accurate results can be obtained. In comparison with the standard lagrange shape function the NURBS functions have distinct advantages. The computational cost and the time of work can be spared by using isogeometric analysis. This shows high significance for complex finite element analysis in CAD.
