Abstract: Climate change and air pollution are among the key drivers of energy transition worldwide. The adoption of renewable resources can act as a peacemaker and give stability regarding the damaging effects of fossil fuels challenging public health as well as the tension made between countries in global prices of oil and gas. Understanding the potential and capabilities to produce renewable energy resources is a crucial prerequisite for countries to utilize them and to scale up clean and stable sources of electricity generation. This paper presents a hybrid methodology that combines the data envelopment analysis (DEA) Window model, and fuzzy technique for order of preference by similarity to ideal solution (FTOPSIS) in order to evaluate the capabilities of 42 countries in terms of renewable energy production potential. Based on three inputs (population, total energy consumption, and total renewable energy capacity) and two outputs (gross domestic product and total energy production), DEA window analysis chose the list of potential countries, including Norway, United Kingdom, Kuwait, Australia, Netherlands, United Arab Emirates, United States, Japan, Colombia, and Italy. Following that, the FTOPSIS model pointed out the top three countries (United States, Japan, and Australia) that have the greatest capabilities in producing renewable energies based on five main criteria, which are available resources, energy security, technological infrastructure, economic stability, and social acceptance. This paper aims to offer an evaluation method for countries to understand their potential of renewable energy production in designing stimulus packages for a cleaner energy future, thereby accelerating sustainable development.

Keywords: renewable energy; capability; DEA; window model; triangular fuzzy number; TOPSIS; decision making

1. Introduction

The burning of fossil fuels, such as coal and oil, which accounts for two-thirds of all greenhouse gases [1], has dramatically increased the carbon dioxide content of the earth’s atmosphere over the last century. As a result, the earth’s surface temperature has risen by 1.14 degrees Celsius since records began in the late 19th century [2]. The effects on the environment, such as more intense heat waves, rising sea levels, and changes in plants and animals, are already being noticeable today. The intergovernmental panel on climate change (IPCC) assumes that climate change will cause considerable economic damage, which could become even worse in the future [3]. The energy sector alone, from generation to consumption, contributes a lot to the exhaustion of greenhouse gases in the air. The electricity demand has grown tremendously, which became the driving force for developed countries to enhance their energy production using any means.
Renewable energies play an important role in mitigating the negative consequences of climate change. For example, analyses by the international renewable energy agency (IRENA) show that 90% of the carbon dioxide reductions are needed to meet nationally agreed climate targets can be achieved through safe, reliable, and affordable strategies using renewable energy and energy efficiency [4]. In doing so, many countries and global organizations have made significant strides towards achieving more sustainable alternatives for energy generation using renewable methods. The development of solar and wind energies has received considerable attention, as their sources are almost inexhaustible and easy to acquire anywhere. Other countries have obtained benefits from having abundant sources of geothermal energy. Some are also exploiting their tidal or wave to generate electricity, yet not many countries can have enough wave power. Aside from these already available sources of renewable energy, other countries are also investigating producing hydrogen fuel as another source of energy, since this can be another cheaper way of energy generation, meanwhile reducing the emission of greenhouse gases [5].

However, it has raised questions regarding how a country can exploit the potential or even determine its capacities in renewable energy production. Many countries are now producing energy using renewable sources, but not everyone is capable of adopting this new trend in energy generation. Thus, for each nation, the evaluation of its potential in producing renewable energies is the pre-requisite step in the ambition of developing renewable energy systems. Simply stated, this assessment process can be regarded as a multiple criteria decision-making (MCDM) problem that requires various inputs and criteria. A general MCDM process model is shown in Figure 1 [6,7]. MCDM methods are often the first choice of researchers to construct evaluation frames in different industries. For renewable energy sector, MCDM techniques are commonly used to evaluate sources, efficiency, technologies, alternatives, projects, and policies, to name a few. For example, Ertay et al. [8] evaluate the renewable energy alternatives for a case study in Turkey, proposing MACBETH and AHP-based multicriteria methods under fuzziness. Considering the selection of suitable renewable energy policy as a significant issue, Mousavi et al. [9] solved two real case studies in developing countries on renewable energy policy selection problem. In this study, ELECTRE was presented under a hesitant fuzzy environment for solving the multi-attribute group decision-making (MAGDM) problems in energy sector. In order to determine the most suitable low-emission energy technologies development in Poland, Ligus and Peternek [10] introduced a hybrid MCDM model based on FAHP and FTOPSIS, considering a number of criteria that are defined from the viewpoint of accomplishment of sustainable development policy goals. In a typical problem of site selection for installing renewable energy plants, Nazari et al. [11] considered four different locations as the primary options for utility scale PV plants installation and the best choice is selected based on a MADM method, TOPSIS. Wang et al. [12] applied the SWOT analysis and fuzzy AHP method to assess the renewable resources of Pakistan.

![Generalized framework for MCDM process](image.png)

**Figure 1.** Generalized framework for MCDM process [6,7].

This study will focus on determining which countries have the most capabilities in producing renewable energy by combining quantitative and qualitative methods of analysis. The quantitative step involves the use of Pearson’s correlation and the Window model of data envelopment analysis (DEA), while the qualitative one will use analysis with the fuzzy technique for order of preference by similarity to ideal solution (FTOPSIS). In detail, the DEA Window model is used for selecting the candidate countries for the
period 2010–2019 based on input factors, which are population, total energy consumption, and total renewable energy capacity, while gross domestic product and total energy production are considered to be output factors. Afterward, FTOPSIS is used for ranking all potential countries based on five main criteria, which are available resources, energy security, technological infrastructure, economic stability, and social acceptance. In the FTOPSIS model, the rating of each alternative and the weight of each criterion are identified by linguistic value using triangular fuzzy numbers. The managerial implications of this study enable countries to understand and expedite their potential in renewable energy production at the center of recovery efforts to secure a structural downward trend in carbon emissions and achieve more resilient and sustainable development.

The study focuses on two outlooks, first is the use of this combined MCDM model as an alternative to other methods that are used in the assessment of renewable energy capabilities. These methods have better advantages when compared to others and they will be discussed in the succeeding sections. In this paper, the problem of renewable energy production capability is solved using triangular fuzzy set theory, which is effective in handling qualitative data and uncertainty of experts' judgment. Thus, it leads to more robust and sustainable results when considering fuzzy conditions than deterministic ones. The second outlook is to provide the countries under studied the analysis on how they perform in terms of renewable energy utilization and through the presence of criteria used, they can assess which aspects they do best and need to be improved.

The second section provides details regarding how previous studies describe the methods and they were used in several applications. The third section describes the materials and methods that will be used. The fourth section will provide data collection, and the results analysis on the output data and determine which of the countries are the most suitable to invest in renewable power generation. Finally, the last section will discuss concluding remarks.

2. Literature Review

Several studies have been conducted in order to evaluate the renewable energy sector while using different methods under various scopes. An example of these studies is from Lee and Zhong [13], in which they are able to construct a composite index that will evaluate the 50 countries’ concerns in investment through measurement of their social, environmental, government, and economic situation, in terms of renewable energy production. With the use of historical data from the year 2004 to 2013, they were able to devise an investment tool that some investors can use for decision making to guide them with their investment opportunities. Another study from Iddrisu and Bhattacharyya [14] focused on the creation of a sustainability index in which this aspect is a common lack to some energy indicators. Capturing the sustainability aspect will improve the measurement tools in evaluating the energy efficiency of many countries; this study finds that the index has a positive correlation to the existing energy development and human development indices. The measurement indices for the evaluation of energy sustainability have been a common interest for some research studies, including one from Cirstea et al. [15], in which they were also able to develop what they called the renewable energy sustainability index. The method was applied to 15 countries in Europe in assessing their weaknesses and strengths in terms of renewable energy production. This index enables policymakers to devise strategic solutions in improving their country’s positive indicators and reduce the effects of the negative factors.

In spite of several measurement indices that are designed to evaluate any energy systems, this may not be sufficient, as this only covers quantitative factors and it may be improved by integrating other methods, such as DEA and TOPSIS. Some other studies were also conducted using some models of DEA, such as the one from Wang et al. [16] in which three DEA models were used (CCR, BCC, and SBM) to evaluate the total factor efficiency of 46 potential solar power plant locations in Vietnam. After which the TOPSIS method was applied for the ranking of the best locations. The combination of these methods made
up the multicriteria decision making (MCDM) technique that is commonly used for many types of industries. Another study was also conducted in Turkey by Şengül et al. [17], wherein the authors fuzzified the TOPSIS analysis to rank the best energy supply in the country. The study finds out that the best energy source is hydropower, followed by geothermal, regulator, and wind power. Kaya and Kahraman [18] used the same method and integrated the fuzzy analytical hierarchy process (AHP) in order to provide a quantitative and qualitative evaluation of the different energy systems and removes the uncertainties in the data set. Factors, such as technical, economic, environmental, and social aspects, were highly considered by the experts to provide more comprehensive assessments of several energy supplies such as biomass, hydro, wind, solar, and nuclear.

Based on a generalized framework for multi-criteria method selection, Table 1 summarizes the literature of the proposed methods concerning global renewable energy assessment. Most previous studies have applied DEA and DEA-based modeling approaches, for example, CCR (Charnes–Cooper–Rhodes) [19–22], Undesirable Output [23–28], Malmquist [24,29–31], and Window [27]. To define and obtain weights for criteria and sub-criteria in multi-criteria evaluation of renewable energy alternatives, the most commonly used weighting MCDM methods are analytical hierarchy process (AHP)/Fuzzy AHP [19,21,32–34] and the technique for order of preference by similarity to ideal solution (TOPSIS)/Fuzzy TOPSIS [20,35–38]. Some frequently applied methods are bootstrap [22,28,31], stochastic frontier analysis (SFA) [26,39], ordinary least square (OLS) [40,41], regression model [41–43], and hybrid approaches [19–22,24,26–28,31,41]. Other recently used multi-criteria decision making (MCDM) methods are visekriterijumska optimizacija i kompromisno resenje (VIKOR) and preference ranking organization method for enrichment of evaluations (PROMETHEE II) [33,44–49], and other MCDM approaches [20,21,33,50,51].

In this study, the authors considered the DEA Window analysis and FTOPSIS method based on their advantages and purposes. The DEA Window is capable of measuring the relative technical efficiency of DMUs from one period to another while taking their efficiency performance into consideration. While FTOPSIS can provide a ranking of alternatives based on qualitative criteria. Unlike the ordinary TOPSIS, FTOPSIS operates in the presence of an uncertain environment, which makes the results more robust and specific. The combination of these two methods is suitable for this paper. These methods will be discussed more in the fourth section of this study (i.e., theoretical framework). It is important to note that the objective of the paper is to propose a combined model of DEA Window and Fuzzy TOPSIS in order to come up with reliable efficiency and ranking results. To the best of our knowledge, our paper is the first study to propose an integrated model that combines the Window model of data envelopment analysis (DEA), and fuzzy technique for order of preference by similarity to ideal solution (FTOPSIS), for the evaluation of renewable energy production capabilities of 42 potential countries.

3. Research Process

This paper proposes a hybrid DEA window model and FTOPSIS approach for measuring the capabilities of renewable energy production. Figure 2, depicted the research flow chart, describes how this study will be conducted. The process starts by identifying the goals and objectives while selecting the proper decision-making units (DMUs). This paper considers 42 countries, as DMUs, spreading from America, Europe, Asia, to Africa, which can be highly established and effective in utilizing their renewable energy.

In the first stage, the DEA window model is used to choose lists of candidate potential countries. The input and output factors must be well distinguished, as these factors also have a great influence on the DEA method. Based on the objective of the paper and the list of common input and output factors for renewable energy potential assessments in previous studies (Table 2). This paper considers three inputs (population, total energy consumption, and total renewable energy capacity) and two outputs (gross domestic product, total energy production). A Pearson correlation analysis will be applied to the data to ensure that the values in the input and output factors are consistent with the stochastic requirement of DEA. Additionally, once all of the values are correlated with one another, DEA will proceed. The Window DEA model was chosen to provide the technical efficiency of the DMUs in a certain period. This will enable the author to see whether the DMUs have been efficient or not from one year to another. As to the DEA Window results, the 42 countries will be downlisted to 10 countries. The chosen 10 countries are those that have achieved the highest efficiency scores among the others.

In the second stage, FTOPSIS is used to rank all of the potential countries, which is from DEA Window model. Table 3 lists down the different criteria used by several studies. These criteria are also considered for use in this paper, including the availability of resources, energy security, technological infrastructure, economic stability, and social acceptance. Within the context of energy capability assessments, availability of resources, energy security, and technological infrastructure are traditional key system measurements. Additionally, the focus on sustainable development has increased, so economic stability and social acceptance are quintessential factors in long-term profitability and resilience.
The final optimal ranking is suggested according to the shortest geometric distance from the fuzzy positive ideal solution (NPIS) and the longest geometric distance from the fuzzy negative ideal solution (FNIS) values. This method will be able to determine the top three countries that have the greatest capabilities in producing renewable energies.

4. Theoretical Framework

4.1. DEA Window Model

The Pearson is generally used in previous studies, which describes the linear relationship of two factors, where +1 presents a total positive linear, 0 presents no linear, and −1 presents a total negative linear. Isotonic is an essential DEA data assumption. The relationship between the inputs and outputs will be verified before using the DEA model, which means that it should be in a total positive linear relationship. The Pearson correlation index is one of the best statistical tests for estimating the correlation between two factors. The Pearson correlation coefficient formula is given as

\[ r_{ab} = \frac{\sum_{i=1}^{n} a_i b_i - \frac{\sum_{i=1}^{n} a_i \sum_{i=1}^{n} b_i}{n}}{\sqrt{\left(\sum_{i=1}^{n} a_i^2 - \frac{(\sum_{i=1}^{n} a_i)^2}{n}\right) \left(\sum_{i=1}^{n} b_i^2 - \frac{(\sum_{i=1}^{n} b_i)^2}{n}\right)}} \]  

(1)

where \( n \) is the sample size; \( a_i, b_i \) denote the individual sample points that are related to \( i \).

Because the homogeneity and isotonicity are two critical DEA data assumptions, these use the correlation test as an imperative step before using DEA. It is certain that there is an isotonic condition between input and output factors. The input and output data must have a positive correlation (i.e., the closer the value to +1, the better positive linear correlation), as can be seen in Figure 3.

The DEA Window model is nonparametric in the DEA method. It is a useful model to detect the tendency of DMUs over multiple periods with respect to multiple inputs and outputs [75]. The procedures of DEA window model are presented, as follows.

Assume that the DEA window model has \( r \) inputs to produce \( s \) outputs. Let \( DMU_n^t \) represent the \( n^{th} \) DMU with \( (n = 1, 2, 3, \ldots, N) \), which are observed in \( T \) period with \( (t = 1, 2, 3, \ldots, T) \). Thus, the sample has \( N \times T \) observations and an observation \( n \) in period \( t \). Subsequently, the input and output vectors of \( DMU_n^t \) are shown as follows [76].

Equation (2) presents the \( r \)-dimensional input vector of \( DMU_n^t \).

\[ A_n^t = \left[a_{n1}^{t1}, a_{n2}^{t1}, \ldots, a_{nr}^{t1}\right]' \]  

(2)

Equation (3) presents the \( s \)-dimensional output vector of \( DMU_n^t \).

\[ B_n^t = \left[b_{n1}^{t1}, b_{n2}^{t1}, \ldots, b_{ns}^{t1}\right]' \]  

(3)

The window starting at the time \( k, 1 \leq k \leq T \) and with the width \( w, 1 \leq w \leq T - k \), is denoted by \( k_w \) and has \( N \times w \) observations. Consequently, the matrix of inputs \( (A_{k_w}) \) and the outputs \( (B_{k_w}) \) of each window \( (k_w) \) are presented, as follows.
The matrix of inputs is presented in Equation (4).

$$A_{kw} = \begin{bmatrix} a_{1}^{k}, a_{2}^{k}, \ldots, a_{N}^{k}, a_{1}^{k+1}, a_{2}^{k+1}, \ldots, a_{N}^{k+1}, a_{1}^{k+w}, a_{2}^{k+w}, \ldots, a_{N}^{k+w} \end{bmatrix}$$ (4)

The matrix of outputs is presented in Equation (5).

$$B_{kw} = \begin{bmatrix} b_{1}^{k}, b_{2}^{k}, \ldots, b_{N}^{k}, b_{1}^{k+1}, b_{2}^{k+1}, \ldots, b_{N}^{k+1}, b_{1}^{k+w}, b_{2}^{k+w}, \ldots, b_{N}^{k+w} \end{bmatrix}$$ (5)

The input-oriented DEA window model for DMU_{t} is solved using a form of linear programming, as can be seen in the mathematical model (6), below.

$$\varnothing'_{kw} = \min_{\varnothing, \alpha} \varnothing$$

such that

$$-A_{kw}\alpha + \varnothing'_{t} \geq 0$$

$$B_{kw}\alpha - b_{t}' \geq 0$$

$$\alpha_{n} \geq 0 \quad (n = 1, \ldots, N \times w)$$ (6)

4.2. Fuzzy TOPSIS Model

Triangular fuzzy number is the basic concept of fuzzy theory to deal with uncertainty environment problems [77]. The fuzzy technique for order preference by similarity to ideal solution (FTOPSIS) was extended from the TOPSIS method for group decision-making under fuzzy environment [78]. Based on the concept of TOPSIS, the optimal result of FTOPSIS is defined by calculating the distance between the fuzzy positive ideal solution (FPIS) and the fuzzy negative ideal solution (FNIS). The procedures of FTOPSIS are presented, as follows.

Step 1: identifying the criteria that significantly affect renewable energy production by a summary of previous literature. Subsequently, decision-makers assess the importance of the criteria using the linguistic weighting value in Table 4.

| Symbol | Definition    | Scale of Triangular Fuzzy Number |
|--------|--------------|----------------------------------|
| VL     | Very low     | (0, 0, 0.1)                      |
| L      | Low          | (0, 0.1, 0.3)                    |
| ML     | Medium low   | (0.1, 0.3, 0.5)                  |
| M      | Medium       | (0.3, 0.5, 0.7)                  |
| MH     | Medium high  | (0.5, 0.7, 0.9)                  |
| H      | High         | (0.7, 0.9, 1)                    |
| VH     | Very high    | (0.9, 1, 1)                      |

Step 2: evaluating the ratings of all alternatives (i.e., by decision-makers) with respect to criteria using the linguistic rating value in Table 5.

| Symbol | Definition     | Scale of Triangular Fuzzy Number |
|--------|----------------|----------------------------------|
| VP     | Very poor      | (0, 0, 1)                        |
| P      | Poor           | (0, 1, 3)                        |
| MP     | Medium poor    | (1, 3, 5)                        |
| F      | Fair           | (3, 5, 7)                        |
| MG     | Medium good    | (5, 7, 9)                        |
| G      | Good           | (7, 9, 10)                       |
| VG     | Very good      | (9, 10, 10)                      |
where $\tilde{x}_{ij}$ are the linguistic values by using triangular fuzzy number, $\tilde{x}_{ij} = (a_{ij}, b_{ij}, c_{ij})$, $\bar{w}_j = (w_{j1}, w_{j2}, w_{j3})$; $\tilde{x}_{ij}^k$, $\tilde{x}_{ij}^k$ denote the performance rating and the important weight of $k^{th}$ decision-makers, respectively, $\tilde{x}_{ij}^k = (a_{ij}^k, b_{ij}^k, c_{ij}^k)$, $\tilde{w}_j^k = (w_{j1}^k, w_{j2}^k, w_{j3}^k)$; $i = 1, 2, \ldots, m$, $j = 1, 2, \ldots, n$.

Step 4: building fuzzy normalized decision matrix, as shown in Equations (11)–(15).

$$\tilde{R} = [\tilde{r}_{ij}]_{m \times n}; i = 1, 2, \ldots, m; j = 1, 2, \ldots, n$$

$$\tilde{r}_{ij} = \left(\frac{a_{ij}}{c_{ij}}, \frac{b_{ij}}{c_{ij}}, \frac{c_{ij}}{c_{ij}}\right), j \in B$$

$$\tilde{r}_{ij} = \left(\frac{a_{ij}^-}{c_{ij}^-}, \frac{a_{ij}^0}{b_{ij}^-}, \frac{a_{ij}^0}{a_{ij}^-}\right), j \in C$$

$$c_{ij}^+ = \max\{c_{ij} | i = 1, 2, \ldots, m\} \text{ if } j \in B$$

$$a_{ij}^- = \min\{a_{ij} | i = 1, 2, \ldots, m\} \text{ if } j \in C$$

where $B, C$ are set of benefit and cost criteria, respectively.

Step 5: building fuzzy weighted normalized decision matrix, Equations (16)–(17).

$$\tilde{V} = [\tilde{v}_{ij}]_{m \times n}; i = 1, 2, \ldots, m; j = 1, 2, \ldots, n$$

$$\tilde{v}_{ij} = \tilde{r}_{ij}(\times)\tilde{w}_j$$

Step 6: calculating FPIS $A^+$ (the most level) and FNIS $A^-$ (the worst level).

$$A^+ = \left(\tilde{v}_{ij}^+, \ldots, \tilde{v}_{ij}^+, \ldots, \tilde{v}_{ij}^+\right)$$

$$A^- = \left(\tilde{v}_{ij}^-, \ldots, \tilde{v}_{ij}^-, \ldots, \tilde{v}_{ij}^-\right)$$

where $\tilde{v}_{ij}^+ = (1, 1, 1)$, $\tilde{v}_{ij}^- = (0, 0, 0)$, $j = 1, 2, \ldots, n$.

Step 7: calculating the distance $(d_i^+)$ of each alternative, i.e., distance measurement between two fuzzy numbers.

$$d_i^+ = \sum_{j=1}^{n} d\left(\tilde{v}_{ij}, \tilde{v}_{ij}^+\right), i = 1, 2, \ldots, m$$
\[ \tilde{d}_i = \sum_{j=1}^{n} d\left( \tilde{v}_{ij}, \tilde{v}_j \right), i = 1, 2, \ldots, m \]  

(21)

Step 8: calculating the closeness coefficient of each alternative, as in Equation (20).

\[ \overline{CC}_i = \frac{\tilde{d}_i^-}{\tilde{d}_i^- + \tilde{d}_i^+}, i = 1, 2, \ldots, m \]  

(22)

Step 9: determining the ranking order of all alternatives. The optimal solution is closer to the FPIS \( A^+ \) (the most level) and farther from the FNIS \( A^- \) (the worst level) as \( \overline{CC}_i \) approaches to 1.

5. Results Analysis

5.1. Data Collection

Table 6 shows a list of countries used in the paper. There are 42 countries, including 14 countries in the European Union, four countries in the commonwealth of independent states (CIS), two countries in North America, five countries in Latin America, seven countries in Asia, two countries in the Pacific, four countries in Africa, and four countries in the Middle East. Because of unavailable data, this paper is limited to the number of countries. Hence, there are 42 countries with renewable energy where the related data are collected for the period 2010–2019, from Enerdata [79], IRENA [80], and Worldbank [81]. Table 7 shows descriptive statistics of inputs and outputs. Note that population (PO, unit: million), total energy consumption (TEC, unit: Mtoe), total renewable energy capacity (TREC, unit: MW), gross domestic product (GDP, unit: billion), and total energy production (TEP, unit: Mtoe).

Table 6. List of countries used in the paper.

| DMUs | Country       | Region       | DMUs | Country       | Region       |
|------|---------------|--------------|------|---------------|--------------|
| 1    | Belgium       | European Union| 21   | Argentina     | Latin America|
| 2    | Czech Republic| European Union| 22   | Brazil        | Latin America|
| 3    | France        | European Union| 23   | Chile         | Latin America|
| 4    | Germany       | European Union| 24   | Colombia      | Latin America|
| 5    | Italy         | European Union| 25   | Mexico        | Latin America|
| 6    | Netherlands   | European Union| 26   | China         | Asia         |
| 7    | Poland        | European Union| 27   | India         | Asia         |
| 8    | Portugal      | European Union| 28   | Indonesia     | Asia         |
| 9    | Romania       | European Union| 29   | Japan         | Asia         |
| 10   | Spain         | European Union| 30   | Malaysia      | Asia         |
| 11   | Sweden        | European Union| 31   | South Korea   | Asia         |
| 12   | United Kingdom| European Union| 32   | Thailand      | Asia         |
| 13   | Norway        | European Union| 33   | Australia     | Pacific      |
| 14   | Turkey        | European Union| 34   | New Zealand   | Pacific      |
| 15   | Kazakhstan    | CIS          | 35   | Algeria       | Africa       |
| 16   | Russia        | CIS          | 36   | Egypt         | Africa       |
| 17   | Ukraine       | CIS          | 37   | Nigeria       | Africa       |
| 18   | Uzbekistan    | CIS          | 38   | South Africa  | Africa       |
| 19   | Canada        | North America| 39   | Iran          | Middle East  |
| 20   | United States | North America| 40   | Kuwait        | Middle East  |
|      |               |              | 41   | Saudi Arabia  | Middle East  |
|      |               |              | 42   | United Arab Emirates | Middle East |

Note: CIS denotes commonwealth of independent states.
It is very important to check that all of the inputs and outputs must have a positive correlation before applying the DEA model. The Pearson correlation test is applied to check data assumptions (i.e., homogeneity and isotonicity condition). The values of coefficient correlation are always between $-1$ and $+1$. Table 8 shows the Pearson correlation index of inputs and outputs. The results indicate that the correlation among these factors is in a positive relationship and significant at the 0.01 level. Hence, the collected data can be used for the DEA window model.

### Table 7. Descriptive statistics of input and output factors.

| Factor                          | Minimum | Maximum  | Mean   | Std. Deviation |
|---------------------------------|---------|----------|--------|----------------|
| Population                      | 2.99    | 1397.72  | 125.31 | 279.36         |
| Total energy consumption        | 18      | 3284     | 277.89 | 547.07         |
| Total renewable energy capacity | 0       | 758,626  | 37,848.41 | 82,491.48    |
| Gross domestic product          | 46.68   | 21,433.23 | 1636.98 | 3165           |
| Total energy production         | 5       | 2684     | 280.38 | 497.12         |

Note: ** denotes correlation is significant at the 0.01 level (2-tailed).

### 5.2. Results of DEA Window Model

Figure 4 shows the average efficiency score of the whole countries, which significantly fluctuated for the period 2010–2019. From 2010–2011, the average score increased from 0.56 to 0.6 (i.e., the peak value for the whole period). From 2011–2016, the average score continuously decreased. In particular, the average score steadily decreased to 0.59 in 2014, and then dramatically dropped to 0.53 in 2016 (i.e., the bottom value for the whole period). From 2016–2018, the average score began to recover, increased to 0.56 in 2018, and then suddenly dropped to 0.55 in 2019 due to the impact of the Covid-19 crisis on renewable energy systems around the world [82].

In this stage, DEA window model, i.e., a useful model of DEA to detect the tendency of DMUs over multiple periods with respect to multiple inputs and outputs, is used to choose lists of candidate potential countries based on input factors, which are population, total energy consumption, total renewable energy capacity, and output factors, which are gross domestic product and total energy production. Table 9 shows the average efficiency ranking of 42 countries for the whole period 2010–2019. From the results, the top 10 potential countries with high average efficiency score in 2010–2019 are Norway, United Kingdom, Kuwait,
Australia, Netherlands, United Arab Emirates, United States, Japan, Colombia, and Italy. These candidate countries are used for ranking in the next stage using FTOPSIS model.

![Figure 4. The average efficiency score for the period 2010–2019.](image)

5.3. Results of Fuzzy TOPSIS Model

The top 10 potential countries with a higher average technical efficiency in renewable energy production, which were selected from the results of DEA window model, are used for ranking using the FTOPSIS model. In the FTOPSIS model, the final optimal ranking is suggested based on five main criteria, which are available of resources, energy security, technological infrastructure, economic stability, and social acceptance, as can be seen in Figure 5. These five main criteria that significantly affect renewable energy production are selected according to the decision-makers’ experience and relevant studies in the past few decades.

![Figure 5. The hierarchical tree of FTOPSIS model.](image-url)
According to the procedures of FTOPSIS, fuzzy decision matrix and fuzzy weights of all alternatives, fuzzy normalized decision matrix, and fuzzy weighted normalized decision matrix are presented in Tables 10–12, respectively.

### Table 10. Fuzzy decision matrix and fuzzy weights of all alternatives.

|   | C1       | C2       | C3       | C4       | C5       |
|---|---------|---------|---------|---------|---------|
| A1 | (1, 3, 5) | (7.667, 9.333, 10) | (7.667, 9, 9.667) | (6.333, 7.667, 8.333) | (7.667, 9.333, 10) |
| A2 | (5.667, 7.667, 9.333) | (6.333, 8, 9.333) | (7.667, 9, 9.667) | (5.667, 7.667, 9) | (6.333, 8, 9.333) |
| A3 | (7, 9, 10) | (6.333, 8.333, 9.667) | (5.667, 7.333, 8.333) | (5.667, 7.667, 9) | (5.667, 7.667, 9.333) |
| A4 | (5, 7, 9) | (7.667, 9.333, 10) | (6.333, 8, 9.333) | (8.333, 9.667, 10) | (7, 8.667, 9.667) |
| A5 | (5.7, 8.667) | (5.667, 8.667, 9.333) | (7.667, 9, 9.667) | (7.667, 9.333, 10) | (7.667, 9.333, 10) |

As the final ranking from FTOPSIS model, Table 13 and Figure 6 indicate the top three countries that have the most capabilities in renewable energy production, in which the United States, Japan, and Australia ranked the first, second, and third, with scores of 0.5774, 0.5767, and 0.5714, respectively.
6. Discussions and Conclusions

For an evaluation of renewable energy production potential of 42 countries spreading from America, Europe, Asia, to Africa, this study proposed a hybrid methodology that combines the data envelopment analysis (DEA) Window model, and fuzzy technique for order of preference by similarity to ideal solution (FTOPSIS). In the first stage, the DEA Window model was applied to choose the potential DMUs (countries) for the period 2010–2019 based on input factors, which are population, total energy consumption, and total renewable energy capacity, while gross domestic product and total energy production are considered to be the output factors. Thus, 10 potential countries, including Norway, United Kingdom, Kuwait, Australia, Netherlands, United Arab Emirates, United States, Japan, Colombia, and Italy, were selected. In the next stage, FTOPSIS was used for ranking all potential countries based on five main criteria, which are available resources, energy security, technological infrastructure, economic stability, and social acceptance. In the FTOPSIS model, the rating of each alternative and the weight of each criterion are identified by linguistic value using triangular fuzzy numbers. By doing that, the FTOPSIS model pointed out the top three countries (United States, Japan, and Australia) that have the most capabilities in producing renewable energies.

The generation of renewable energy in the United States reached an all-time high in 2019 of 11.6 billion British thermal units [83]. In another context, Australia continues to lead the world in deploying renewable energy according to a new analysis from The Australian National University (ANU), namely, the per capita roll-out of solar and wind-generated energy contributes to lower greenhouse gas emissions and declining electricity prices [84].

Table 13. Distance measurement and closeness coefficient of each alternative.

| Alternative | Countries            | $d_1^+$ | $d_1^-$ | CC$_i$ | Rank |
|-------------|----------------------|---------|---------|--------|------|
| A1          | Norway               | 2.53389 | 2.78231 | 0.52336 | 7    |
| A2          | United Kingdom       | 2.44247 | 2.91216 | 0.54386 | 4    |
| A3          | Kuwait               | 2.50178 | 2.86652 | 0.53397 | 5    |
| A4          | Australia            | 2.30395 | 3.07180 | 0.57142 | 3    |
| A5          | Netherlands          | 2.52475 | 2.79734 | 0.52561 | 6    |
| A6          | United Arab Emirates | 3.51716 | 1.71309 | 0.32662 | 10   |
| A7          | United States        | 2.27166 | 3.10339 | 0.5774  | 1    |
| A8          | Japan                | 2.27273 | 3.09668 | 0.57673 | 2    |
| A9          | Colombia             | 2.74876 | 2.59387 | 0.48551 | 9    |
| A10         | Italy                | 2.60542 | 2.75456 | 0.51391 | 8    |

Figure 6. Final ranking order of FTOPSIS model.
For Japan, the country is known as one of the world’s biggest energy consumers and energy importers, dependent on imports from other countries for almost 96% of its primary energy production. The government recognized the energy supply sensitivity and decided to restructure the diversification of the energy mix, renewable energies, enhancement of energy performance, and reduction of carbon emissions. Different renewable energy technologies are also now being taken into account as substitute sources of energy and promising ways of supplying domestic energy, as well as crucial factors to enhance the reliability of the energy supply [85].

The contributions of the paper are three-fold. (1) This study is the first to propose a hybrid MCDM model that combines the data envelopment analysis (DEA) Window model, and fuzzy technique for order of preference by similarity to ideal solution (FTOPSIS) for the evaluation of renewable energy production potential. (2) The results of this paper provide comprehensive and practical insights for 42 countries around the world to review and investigate their renewable energy potential. Besides mitigating climate change and accelerating sustainable development, renewable energy is also key in the responses to unprecedented crises, such as the Covid-19 pandemic crisis [86]. (3) The authors expect that this study can be used as a useful guideline for countries to evaluate their potential not only in renewable energy, but also in any industries’ development.

For future studies involving quantitative and qualitative approaches, the authors suggest investigating new assessment factors that can impact the production capacities of renewable energy in order to enhance the resolution of the empirical results. The procedure and methods that were introduced by the paper can also be considered to explore the capabilities of many countries in other aspects of energy, such as the use of hydrogen fuel. Implementing these methods will only require tailor fitting the criteria to see whether some countries are in a state of low or high readiness in utilizing earth-friendly and low-cost energy production and consumption. The authors hope that future research regarding renewable energies can be helpful for many countries’ governments and policymakers to assess their current performance in terms of their use of their renewable resources. This paper is also evidence that combining MCDM methods can be a more effective evaluation model. Their results can be compared together to obtain highly accurate results.
