ABSTRACT
Background: Aronia melanocarpa (Michx.) Elliot fruits are very rich in polyphenols – procyanidins, flavonoids, and phenolic acids.
Objective: On rat hepatocytes, isolated by two-stepped collagenase perfusion, we investigated the effect of Aronia melanocarpa fruit juice (AMFJ) in two models of liver toxicity caused by i) metabolic bioactivation of carbon tetrachloride (CCl4), and ii) tert-butyl hydroperoxide (t-BuOOH)-induced oxidative stress. Materials and Methods: Isolated rat hepatocytes are a suitable model for hepatotoxicity studies. We determined the main parameters of the functional and metabolic status of rat hepatocytes: Cell viability (measured by trypan blue exclusion) and the levels of lactate dehydrogenase (LDH), reduced glutathione (GSH), and malondialdehyde (MDA). These parameters were used to investigate the protective effects of AMFJ in the two toxicity models. The effects of AMFJ were compared with those of silymarin. The cells were treated either with AMFJ or silymarin at increasing concentrations of 5 µg/ml, 10 µg/ml, 30 µg/ml, 50 µg/ml, and 100 µg/ml which were used for measuring of IC50. Results: In both toxicity models – CCl4 and t-BuOOH, AMFJ showed statistically significant cytoprotective and antioxidant activities. AMFJ prevented the loss of cell viability and GSH depletion, decreased LDH leakage and MDA production. The effects of AMFJ at the concentrations of 5, 10, 30, and 50 µg/ml were similar to those of the same concentrations of silymarin, while the effect of the highest AMFJ concentration of 100 µg/ml was higher than that of the same silymarin concentration. The effects were concentration-dependent and more prominent in the t-BuOOH model, compared to those in the CCl4 model. Conclusion: The cytoprotective and antioxidant effects of AMFJ established in this study might be due to its polyphenolic ingredients, which could influence the cytochrome P450-mediated metabolism of the experimental hepatotoxic substances (CCl4 and t-BuOOH) and could act as free radical scavengers. The stronger effects of the highest AMFJ concentration in comparison with that of silymarin were possibly due to the combined presence of different polyphenols in the juice. Key words: Aronia melanocarpa fruit juice, carbon tetrachloride, cytoprotection, isolated hepatocytes, tert-butyl hydroperoxide

INTRODUCTION
Convenient, well-controlled biological model system with high drug-metabolizing capacities, which can be used in experimental toxicology are isolated rat hepatocytes. This in vitro system is a part of recommended tests from the European Centre for the Validation of Alternative Methods (ECVAM). The main goal of ECVAM is to promote the acceptance of alternative methods, which are important for reducing, refining, and replacing the use of laboratory animals. The main enzymes, which play a role in the biotransformation of compounds from natural and synthetic origin, belong to the cytochrome P450 superfamily. These enzymes participate in the bioactivation and detoxification of numerous toxicants and pro-carcinogens. For example, carbon tetrachloride (CCl4) causes liver damage following its cleavage by cytochrome P450 to form the trichloromethyl free radical and the highly reactive trichloromethyl peroxy radical, which covalently bind to lipids and other cellular macromolecules. SUMMARY
- On rat hepatocytes, isolated by two-stepped collagenase perfusion, we investigated the effect of Aronia melanocarpa fruit juice (AMFJ) in two models of liver toxicity caused by i) metabolic bioactivation of carbon tetrachloride (CCl4), and ii) tert-butyl hydroperoxide (t-BuOOH)-induced oxidative stress. In both toxicity models – CCl4 and t-BuOOH, AMFJ showed statistically significant cytoprotective and antioxidant activities. AMFJ prevented the loss of cell viability and GSH depletion, decreased LDH leakage and MDA production. The effects of AMFJ at the concentrations of 5, 10, 30, and 50 µg/ml were similar to those of the same concentrations of silymarin, while the effect of the highest AMFJ concentration of 100 µg/ml was higher than that of the same silymarin concentration. The effects were concentration-dependent and were more prominent in the t-BuOOH model, compared to those in the CCl4 model.
Oxidative damage is widely recognized as being involved in the development of many pathological conditions. The mechanism behind oxidative stress, considered to begin with lipid peroxidation in biomembranes, subsequently can cause structural and functional degeneration, and when it is severe, it may end in cell death. As a pro-oxidant, tert-butyl hydroperoxide (t-BuOOH) has been widely used, and many effects on cell metabolism have been described, e.g., changes in calcium homeostasis, increase of lipid peroxidation, and decrease of mitochondrial membrane potential.[9]

Experiments on isolated hepatocytes are thus a useful model system for evaluation of the toxic effect of various pro-oxidants, which act directly on mitochondrial enzymes. As oxidative stress is known to play a role in the pathogenesis of different diseases, the contribution of dietary polyphenols for their prevention has been widely investigated.[4] Dietary phenolic substances have been extensively studied because of their antioxidant activity. Berries are known as plant material very rich in polyphenols. Aronia melanocarpa (Michx.) Elliot (black chokeberry) fruits are extremely rich in phenolic compounds such as procyanidins, flavonoids (mainly from the subclass of anthocyanins), and phenolic acids (chlorogenic and neochlorogenic). The anthocyanins in A. melanocarpa fruits are water-soluble plant pigments, responsible for the purple and even black color of the fruits.[5]

The aim of the following study is to investigate the possible cytoprotective effects of A. melanocarpa fruit juice (AMFJ) in two models on isolated rat hepatocytes caused by (i) metabolic bioactivation of CCl₄, and (ii) tert-BuOOH-induced oxidative stress. The effects of AMFJ were compared with those of the same concentrations of silymarin.

MATERIALS AND METHODS

Chemicals

The chemicals used in the experiments were: Pentobarbital sodium (Sanofi, France), (N-[2-Hydroxyethyl]piperazine-N’-[ethanesulfonic acid]) (HEPES) (Sigma-Aldrich, Germany), NaCl (Merck, Germany), KCl (Merck), D-glucose (Merck), NaHCO₃ (Merck), KH₂PO₄ (Scharlau Chemie SA, Spain), CaCl₂·2H₂O (Merck), MgSO₄·7H₂O (Fluka AG, Germany), collagenase from Clostridium histolyticum type IV (Sigma-Aldrich), albumin, bovine serum fraction V, minimum 98% (Sigma-Aldrich), EGTA (Sigma-Aldrich), 2-thiobarbituric acid (4,6-dihydroxyquinoline-2-thiol; TBA) (Sigma-Aldrich), trichloroacetic acid (TCA) (Valerus, Bulgaria), 2',2'-dinitro-5,5'-dithiobenzonico acid (DTNB) (Merck), lactate dehydrogenase (LDH) kit (Randox, UK), t-BuOOH (Sigma-Aldrich), and CCl₄ (Merck).

Aronia melanocarpa fruit juice

AMFJ was produced from A. melanocarpa Elliot fruits grown in the Balkan Mountains, Bulgaria, in the region of Troyan. They were handpicked in September, crushed, and squeezed. The juice was filtered, preserved with potassium sorbate (1.0 g/L) and stored at 0°C until the experiment. The contents of phenolic substances in 100 ml AMFJ were:[6] Total phenolics 546.1 mg as gallic acid equivalents, determined spectrophotometrically according to the Folin-Ciocalteu procedure,[7] total procyanidins 312.3 mg determined gravimetrically,[8] anthocyanins such as cyanidin-galactoside 14.3 mg, cyanidin-arabinoside 6.2 mg, cyanidin-xylloside 1.2 mg, and cyanidin-glycoside 0.44 mg, determined by high performance liquid chromatography (HPLC), and phenolic acids such as chlorogenic acid 58.5 mg and neochlorogenic acid 83 mg, determined by HPLC.

Animals

Male Wistar rats (body weight 200–250 g) were used. The rats were housed in plexiglass cages (3 per cage) in a 12/12 light/dark cycle, under standard laboratory conditions (ambient temperature 20 ± 2°C and humidity 72 ± 4%) with free access to water and standard pelleted rat food 53-3, produced according to ISO 9001:2008. Animals were purchased from the National Breeding Center, Sofia, Bulgaria. At least 7 days of acclimatization was allowed before the commencement of the study. The health of animals was monitored regularly by a veterinary physician. The vivarium (certificate of registration of farm No 0072/01.08.2007) was inspected by the Bulgarian Drug Agency to check the husbandry conditions (No A-11-1081/03.11.2011). All performed procedures were approved by the Institutional Animal Care Committee and the principles stated in the European Convention for the Protection of Vertebrate Animals used for Experimental and other Scientific Purposes (ETS 123) (Council of Europe, 1991), and were strictly followed throughout the experiment.[9]

Experimental design

Isolation and incubation of hepatocytes

Rats were anesthetized with sodium pentobarbital (0.2 ml/100 g). An optimized in situ liver perfusion using less reagents and shorter time of cell isolation was performed. The method provided in a higher amount of live and metabolically active hepatocytes.[10] After portal catheterization, the liver was perfused with HEPES buffer (pH = 7.85) +0.6 mM EDTA (pH = 7.85), followed by clean HEPES buffer (pH = 7.85), and finally HEPES buffer containing collagenase type IV (50 mg/200 ml) and 7 mM CaCl₂ (pH = 7.85). The liver was excised, minced into small pieces, and hepatocytes were dispersed in Krebs-Ringer-bicarbonate (KRB) buffer (pH = 7.35) +1% bovine serum albumin.

Cells were counted under the microscope, and the viability was assessed by trypan blue exclusion (0.05%).[11] Initial viability averaged 89%. Cells were diluted with KRB to make a suspension of about 3 × 10⁶ hepatocytes/ml. Incubations were carried out in flasks containing 3 ml of the cell suspension (i.e., 9 × 10⁵ hepatocytes) and were performed in a 5% CO₂ + 95% O₂ atmosphere.[11]

Cell incubation with Aronia melanocarpa fruit juice or silymarin

Cells were incubated in five increasing concentrations either of AMFJ or silymarin: 5 µg/ml, 10 µg/ml, 30 µg/ml, 50 µg/ml, and 100 µg/ml.[12-14] On the basis of these five increasing concentrations, the IC₅₀ was calculated.

Biochemical assays

Lactate dehydrogenase release

After incubation, the hepatocytes were centrifuged for 4 min at 500 rpm, and the supernatant was used for measuring LDH release spectrophotometrically by LDH kit.[11]

Reduced glutathione depletion

At the end of the incubation, isolated rat hepatocytes were centrifuged at 4°C, and the pellet was used for evaluating the level of intracellular reduced glutathione (GSH). It was assessed by measuring nonprotein sulphydryls after precipitation of proteins with TCA, followed by measurement of thiols in the supernatant with DTNB. The absorbance was measured at 412 nm.[11]

Malondialdehyde assay

After incubation, 1 ml from hepatocyte suspension was taken and added to 0.67 ml of 20% (w/v) TCA. After centrifugation, 1 ml of the supernatant was added to 0.33 ml of 6.7% (w/v) TBA and heated at 100°C for 30 min. The absorbance was measured at 535 nm, and the amount of TBA-reactants was calculated using a molar extinction coefficient of malondialdehyde (MDA) 1.56 × 10⁵/M/cm.[11]
Statistical analysis
For statistical analysis of the data, we used statistical program "MEDCALC." Results are expressed as mean ± standard error of the mean for six experiments. The significance of the data was assessed using the nonparametric Mann–Whitney test. A level of P < 0.05 was considered significant. Three parallel samples were used. IC₅₀ was calculated using GraphPad Prism Statistical Software (GraphPad Statistical, Inc.).

RESULTS
Effects of Aronia melanocarpa fruit juice and silymarin in carbon tetrachloride-induced toxicity model
The parameters (cell viability, LDH activity, MDA level, and GSH depletion) determined in the model of CCl₄-induced toxicity (a result of metabolic bio-activation of CCl₄) are presented in Table 1.

The incubation of hepatocytes in 86 µM of CCl₄ resulted in a statistically significant reduction of cell viability by 72% (P < 0.001), increased LDH activity by 620% (P < 0.001), increased lipid peroxidation (MDA) by 293% (P < 0.001), and depletions of cell GSH by 55% (P < 0.001), compared to the control.

In combination with CCl₄, AMFJ caused a statistically significant, concentration-dependent reduction of the damage caused by the hepatotoxic agent [Table 1].

AMFJ at the concentration of 5 µg/ml preserved cell viability by 44% (P < 0.01), at 10 µg/ml – by 60% (P < 0.01), at 30 µg/ml – by 80% (P < 0.01), at 50 µg/ml – by 160% (P < 0.01), and at 100 µg/ml – by 200% (P < 0.01) compared to CCl₄ group. Silymarin preserved cell viability by 100% (P < 0.001) at the concentration of 5 µg/ml, by 112% (P < 0.001) at 10 µg/ml, by 140% (P < 0.01) at 30 µg/ml, by 148% (P < 0.01) at 50 µg/ml, and by 160% (P < 0.01) at 100 µg/ml compared to CCl₄ group.

IC₅₀ for cell viability was 7.5 µg/ml for AMFJ, and lower than 5 µg/ml for silymarin.

AMFJ at the concentration of 5 µg/ml was 30% (P < 0.01), at 10 µg/ml – by 32% (P < 0.01), at 30 µg/ml – by 34% (P < 0.01), at 50 µg/ml – by 44% (P < 0.001), and at 100 µg/ml – by 54% (P < 0.01), compared to CCl₄ group. Silymarin at concentrations of 5 µg/ml (S₅), 10 µg/ml (S₁₀), 30 µg/ml (S₃₀), 50 µg/ml (S₅₀), and 100 µg/ml (S₁₀₀) in a model of CCl₄-induced hepatotoxicity on cell viability, LDH activity, MDA level, and GSH depletion in isolated rat hepatocytes.

Table 1: Effect of AMFJ at concentrations of 5 µg/ml (AMFJ₅), 10 µg/ml (AMFJ₁₀), 30 µg/ml (AMFJ₃₀), 50 µg/ml (AMFJ₅₀), and 100 µg/ml (AMFJ₁₀₀) on cell viability, LDH, MDA, and GSH levels.

| Group       | Cell viability (%) | LDH (µmol/min/mil cells) | MDA (nmol/mil cells) | GSH (nmol/mil cells) |
|-------------|--------------------|--------------------------|----------------------|----------------------|
| Control     | 89 ± 4.5           | 0.121 ± 0.01             | 0.102 ± 0.01         | 20 ± 2.1             |

*P < 0.05; **P < 0.01; ***P < 0.001 versus control; ++P < 0.05; +++P < 0.01; ++++P < 0.001 versus CCl₄, AMFJ: Aronia melanocarpa fruit juice; CCl₄: Carbon tetrachloride; LDH: Lactate dehydrogenase; MDA: Malondialdehyde; GSH: Reduced glutathione.

Effects of Aronia melanocarpa fruit juice and silymarin in tert-butyldihydroperoxide-induced toxicity model
The parameters (cell viability, LDH activity, MDA level, and GSH depletion) determined in the model of t-BuOOH-induced toxicity (a model of oxidative stress) are presented in Table 2.

Hepatocytes incubation with 75 µM t-BuOOH resulted in a statistically significant reduction of cell viability by 74% (P < 0.001), increased LDH activity by 642% (P < 0.001), increased lipid peroxidation (MDA) by 346% (P < 0.001), and depletions of cell GSH by 71% (P < 0.001), compared to the control.

In combination with t-BuOOH, AMFJ caused a statistically significant, concentration-dependent reduction of the damage induced by the hepatotoxic agent [Table 2].

AMFJ preserved cell viability at the concentration of 5 µg/ml by 82% (P < 0.01), at 10 µg/ml – by 91% (P < 0.01), at 30 µg/ml – by 105% (P < 0.01), at 50 µg/ml – by 164% (P < 0.01), and at 100 µg/ml – by 209% (P < 0.01), compared to the t-BuOOH group. Silymarin preserved cell viability by 182% (P < 0.01) at the concentration of 5 µg/ml, by 195% (P < 0.01) at 10 µg/ml, by 205% (P < 0.01) at 30 µg/ml, by 227% (P < 0.01) at 50 µg/ml, and by 264% (P < 0.001) at 100 µg/ml, compared to the t-BuOOH group.

IC₅₀ for cell viability both for AMFJ and silymarin was lower than 5 µg/ml.

The activity of LDH was decreased by AMFJ at 35% (P < 0.001) at 5 µg/ml by by 37% (P < 0.001) at 10 µg/ml by 44% (P < 0.001) at 30 µg/ml, by 47% (P < 0.001) at 50 µg/ml, and by 51% (P < 0.001) at 100 µg/ml, as well as by silymarin by 38% (P < 0.001) at 5 µg/ml, by 44% (P < 0.001) at 10 µg/ml, by 45% (P < 0.001) at 30 µg/ml, by 53% (P < 0.001) at 50 µg/ml, and by 55% (P < 0.001) at 100 µg/ml, compared to t-BuOOH.

IC₅₀ for LDH leakage was 100 µg/ml for AMFJ and 50 µg/ml for silymarin.

MAGDALENA KONDEV A‑BURDINA, et al.: Cytoprotective Effects of Aronia melanocarpa

Pharmacognosy Magazine, Oct-Dec 2015, Vol 11, Issue 44 (Supplement 4)
the concentration of 5 µg/ml, by 48% (P < 0.001) at 10 µg/ml, by 51% (P < 0.001) at 30 µg/ml, by 56% (P < 0.001) at 50 µg/ml, and by 58% (P < 0.001) at 100 µg/ml, compared to t-BuOOH group. MDA level was also decreased by silymarin at the concentration of 5 µg/ml by 50% (P < 0.001), at 10 µg/ml by 53% (P < 0.001), at 30 µg/ml by 60% (P < 0.001), at 50 µg/ml by 63% (P < 0.001), and at 100 µg/ml by 67% (P < 0.001), compared to t-BuOOH group.

IC_{50} for MDA production was 30 µg/ml for AMFJ and 5 µg/ml for silymarin.

AMFJ prevented t-BuOOH-induced GSH depletion at the concentration of 5 µg/ml by 33% (P < 0.001), at 10 µg/ml – by 67% (P < 0.001), at 30 µg/ml – by 100% (P < 0.001), at 50 µg/ml – by 150% (P < 0.001), and at 100 µg/ml – by 217% (P < 0.001), compared to t-BuOOH group. Silymarin prevented GSH depletion by 133% (P < 0.001) at the concentration of 5 µg/ml, by 167% (P < 0.001) at 10 µg/ml, by 200% (P < 0.001) at 30 µg/ml, by 233% (P < 0.001) at 50 µg/ml, and by 250% (P < 0.001) at 100 µg/ml, compared with t-BuOOH group.

IC_{50} for the prevention of GSH depletion was 7.5 µg/ml for AMFJ and lower than 5 µg/ml for silymarin.

**DISCUSSION**

The main mechanisms of xenobiotics-induced hepatotoxicity involve the process of cytochrome P450 (CYP)-mediated bio-activation which leads to the formation of reactive metabolites and oxidative stress. Some of the most widely used toxic agents in hepatotoxicity models acting by different mechanisms are CCl4 and t-BuOOH.

In experimental toxicology, the *in vitro* systems are widely used for the investigation of the xenobiotics biotransformation, and for revealing the possible mechanisms of toxic stress and its prevention. Isolated liver cells are a convenient model system for evaluation of the cytoprotective effects of some promising biologically active compounds, both newly synthesized and derived from plants.

Many natural compounds investigated on isolated rat hepatocytes had their own metabolism and toxicity. For example, benzophenones, isolated from *Hypericum annulatum*, exerted toxic effects at the concentration of 100 µM, which might be due to the formation of toxic metabolites – benzhydrol and p-hydroxybenzophenone.[10] In our preliminary data, we found that administered alone, *A. melanocarpa* juice showed cytotoxic effects on isolated rat hepatocytes. We suggest that some of the juice components (probably polyphenols) had their own metabolism and possibly formed toxic metabolites, which damaged the cells.

In the present experiments, on hepatotoxicity models, we used silymarin as a reference compound. There are data that silybin (the main compound in silymarin) inactivates human cytochrome 3A4 (CYP3A4) and cytochrome 2C9, as well as the main liver glucuronosyltransferases.[11] In this experiment, we used CCl4, a substance subjected to CYP-mediated bio-activation. It is known that CCl4 is activated by cytochrome 2E1 (CYP2E1), as well as CYP2B1, and possibly CYP3A, to form the trichloromethyl radical (•CCl3) which initiates the chain reaction of lipid peroxidation.[12] Preincubation of the hepatocytes with AMFJ resulted in protection against CCl4-induced toxicity. The effects of AMFJ on the examined parameters were similar to those of silymarin at concentrations of 5 µg/ml, 10 µg/ml, 30 µg/ml, and 50 µg/ml. At the highest concentration of 100 µg/ml, AMFJ had stronger effects on all parameters, compared to silymarin at the same concentration.

There are data that in human liver microsomes, some flavonoids exert inhibitory effects on CYP3A activity.[13] The study of Krajka-Kuzniak et al. showed that the forced feeding with *A. melanocarpa* juice alone decreased the activities of cytochrome CYP1A1 and CYP 1A2, and the pretreatment with the juice further reduced the activity of CYP2E1 which was decreased by N-nitrosodiethylamine.[14] In another study, Krajka-Kuzniak et al. demonstrated that plant phenols such as protocatechuic and tannic acids were weak inhibitors of CYP2E1 in rats.[15] In previous studies, we found that anthocyanins, isolated from Bulgarian red wine, showed strong hepatoprotective and antioxidant effects in CCl4-induced hepatotoxicity in vivo comparable to the effect of Vitamin E.[16] They also decreased the lipid dystrophy caused by CCl4.[20] The cytoprotective effect of AMFJ in CCl4-induced toxicity model might be due to possible inhibiting effects on CYP3A and CYP2E1 resulting in a decreased production of toxic CCl4 metabolites. These possible CYP-inhibiting effects might be either due to the polyphenolic components of the juice, or metabolites resulting from their CYP-mediated metabolism.

The other model on isolated rat hepatocytes was t-BuOOH-induced oxidative stress. Two mechanisms for t-BuOOH action were proposed: Depletion of GSH cellular stores and oxidation of functionally important SH groups on mitochondrial enzymes, and/or changes of mitochondrial membrane integrity induced by peroxidation of membrane lipids.[11]

The metabolism of t-BuOOH to free radicals passes through several steps. In microsomal suspension (in the absence of NADPH), t-BuOOH undergoes one-electron oxidation to a peroxy radical (reaction 1), whereas in the presence of NADPH – one-electron reduction to an alkoxyl radical (reaction 2). The toxic agent undergoes β-scission to the methyl radical (reaction 3) in isolated mitochondria and intact cells. All these radicals cause lipid peroxidation.[21,22]
(CH₃)₂COOH → (CH₃)₂COOH + e⁻ + H⁺ (reaction 1)
(CH₃)₂COOH + e⁻ → (CH₃)₂CO + OH⁻ (reaction 2)
(CH₃)₂CO → (CH₃)₂CO + CH₄ (reaction 3)

The results from the present study showed that in the model of t-BuOOH-induced oxidative stress, AMFJ had statistically significant cytoprotective and antioxidant activities, similar to that of silymarin at concentrations of 5 µg/ml, 10 µg/ml, 30 µg/ml, and 50 µg/ml. At the highest concentration of 100 µg/ml, AMFJ had stronger effects on all parameters in comparison with the effects of same concentration of silymarin.

Both AMFJ and silymarin had stronger cytoprotective and antioxidant activities in the t-BuOOH model in comparison with the CCl₄ model. The cytoprotective effects of AMFJ on t-BuOOH-induced oxidative stress were possibly related to its activity as a scavenger of reactive oxygen species (ROS), and these effects were comparable to the effects of silymarin a well-known ROS scavenger.[16] These data correlate with literature data on the pronounced radical scavenging effects of AMFJ, an important mechanism of its antioxidant activity,[23] demonstrated by many authors and reviewed by Chrubasik et al.[24] Kokotkiewicz et al.[25] and Denev et al.[26]

CONCLUSION

In this study, in two different models of toxicity on isolated rat hepatocytes, AMFJ showed statistically significant, concentration-dependent, cytoprotective and antioxidant effects, more prominent in the t-BuOOH compared to the CCl₄ model. We suggest that some of the compounds in AMFJ (probably polyphenols) or their metabolites might have inhibitory effects on some CYP isoforms, playing a role in the metabolism of CCl₄. Thus, in the CCl₄-induced hepatotoxicity model, the cytoprotective effects of AMFJ might be predominantly due to inhibition of the metabolic bio-activation of CCl₄ (possibly by CYP3A4 and CYP2E1). As polyphenols act as powerful radical scavengers, the cytoprotective effects of AMFJ in the t-BuOOH-induced hepatotoxicity model were probably predominantly due to effects on oxidative stress. The effects of AMFJ were comparable to those of silymarin, a well-known hepatoprotector and antioxidant. We suggest that the combined presence of different polyphenolic substances contributes to the stronger cytoprotective and antioxidant effects of the highest AMFJ concentration in comparison with the same concentration of silymarin, in both models of toxicity.

Acknowledgments

We thank the Laboratory of Biologically Active Substances – Plovdiv, Institute of Organic Chemistry with Centre of Phytochemistry – BAS, for determining the contents of polyphenolic substances in AMFJ.
