We study the newly observed charmoniumlike state $Z_{cs}(3985)$ in the framework of chiral effective field theory. The interaction kernel of the $D_s D^* / D_s^* D$ system is calculated up to the next-to-leading order with the explicit chiral dynamics. With the fitted parameters extracted from the $Z_{cs}(3900)$ data as inputs, the mass, width and event distributions of the $Z_{cs}(3985)$ are very consistent with the experimental measurements. Our studies strongly support the $Z_{cs}(3985)$ as the partner of the $Z_{cs}(3900)$ in the SU(3)$_f$ symmetry and the $D_s D^* / D_s^* D$ molecular resonance with the same dynamical origin as the other charged heavy quarkoniumlike states. We precisely predict the resonance parameters of the unobserved states in $D_s^* D^*$, $B_s^* B / B / B^*$ and $B_s^* B^*$ systems, and establish a complete spectrum of the charged charmoniumlike and bottomoniumlike states with the $I(J^P)$ quantum numbers $1(1^+)$ and $\frac{3}{2}(1^+)$, respectively.

Very recently, the BESIII Collaboration observed a new charged charmoniumlike state $Z_{cs}(3985)$ in the $K^+$ recoil-mass spectrum from the process $e^+e^- \to K^+ (D_s^- D^{*0} + D_s^{*-} D^0)$ at the center-of-mass energy $\sqrt{s} = 4.681$ GeV [1]. Its mass and width were measured to be $M_{Z_{cs}} = (3982.5^{+1.8}_{-2.0} \pm 2.1)$ MeV and $\Gamma_{Z_{cs}} = (12.8^{+5.3}_{-4.4} \pm 3.0)$ MeV, respectively. The minimal quark component in $Z_{cs}(3985)$ should be $c\bar{c}s\bar{u}$ rather than the pure $c\bar{c}$ since it is a charged particle with strangeness. The mass of $Z_{cs}(3985)$ is about 100 MeV larger than that of the $Z_{cs}(3900)$, which is the typical mass difference between the $D_s^{(*)}$ and $D^{(*)}$ mesons [2]. Another salient feature of $Z_{cs}(3985)$ is the closeness to the $D_s D^*/D_s^* D$ threshold. It is proposed in Ref. [3] that the newly observed $Z_{cs}(3985)^-$ is the $U$-spin partner of $Z_{cs}(3900)^-$ under the SU(3)$_f$ symmetry. The $Z_{cs}(3985)$ has been intensively studied within a very short time [4–10].

There are large similarities among $Z_{cs}(3985)$ [1], $Z_{cs}(3900)$ [11], $Z_{cs}(4020)$ [12], $Z_{cs}(10610)$ and $Z_{cs}(10650)$ [13] (we will denote these states as $Z_{cs}$, $Z_c$, $Z_c^*$, $Z_b$ and $Z_b^*$ respectively in the following context for simplicity). They all lie few MeVs above the corresponding $D_s D^*$, $D_s^* D$, $D_s^* D^*$, $B B^*$, and $B^* B^*$ thresholds, respectively. They dominantly decay into the open charm/bottom channels [14]. In our recent work [15], we studied the interactions of the isovector $D^{(*)} D^{(*)}$ and $B^{(*)} B^{(*)}$ systems with the chiral effective field theory ($\chi$EFT) up to the next-to-leading order. We find the invariant mass spectra of the open charm/bottom channels can be described well and the peaks originate from the poles in the unphysical Riemann sheet. In other words, the previously observed $Z_{cs}^{(0)}$ states can be well identified as the dynamically generated molecular resonances from the $D^{(*)} D^{(*)}$ and $B^{(*)} B^{(*)}$ interactions. The large similarity between the $Z_{cs}$ and $Z_{cs}^{(0)}$ stimulates us to wonder whether the newly observed $Z_{cs}$ has the same origin. This Letter is devoted to answering this question.

The discoveries of more and more near-threshold exotic states [14, 16–20] indicate some common features of QED and QCD. For the very near-threshold bound states and resonances, physical observables are insensitive to the details of the interaction, which yields universality in both hadronic and atomic sectors [21]. Meanwhile, the hadronic molecules arise from the residual strong interactions between two color singlet objects, which is analogous to molecules bound by the residual interaction of QED. The separable scales in these near-threshold states lead to a feasible approach to improvable expansion, which is the basic idea of effective field theory.

The $\chi$EFT is generally accepted as the modern theory of nuclear forces [22–28], which is built upon two pioneer works of Weinberg [29, 30], and has been successfully applied to describe the low energy $NN$ scatterings, light and medium nuclei [23–25]. Recently, we generalized the framework of $\chi$EFT to the systems with heavy quarks and reproduced the hidden-charm pentaquarks successfully [31, 32]. Within $\chi$EFT, we predicted the existence of strange hidden charm molecular pentaquarks $P_{cs}$ in the isoscalar $\Xi_c D^*$ system [33]. Our prediction was confirmed by the new measurement of LHCb at the $J/\psi \Lambda$ final state [34]. Therefore, it is reliable to utilize the $\chi$EFT to depict the chiral dynamics inside the $D_s D^*/D_s^* D$ systems, likewise. The investigation could be extended further to $Z_{cs}^{(0)}$ in the $D_s^* D^*$ system, as well as their twin partners in the $B_s^* B / B / B^*$ and $B_s^* B^*$ systems under the heavy quark symmetry. Searching for these states would help us to assemble the jigsaw puzzles of dynamical details of the hadronic molecular physics.

Since these states are produced near the corresponding thresholds, the interaction potential of a VP system (V and P denote the vector and pseudoscalar mesons, respectively) with the fixed isospin can be parameterized in the nonrelativistic form,

$$ V = \sum_{i=1}^{6} V_i(p', p)\mathcal{O}_i(p', p, \epsilon, \epsilon^{'\dagger}), \tag{1} $$

where $p$ and $p'$ represent the momenta of initial and final states in the center of mass system (c.m.s), respectively. $\epsilon$...
and $\epsilon^\dagger$ denote the polarization vectors of the initial and final vector mesons, respectively. $V_i$ are the scalar functions to be obtained from the chiral Lagrangians, while $O_i$ are six pertinent operators:

$$
O_1 = \epsilon^\dagger \cdot \epsilon, \quad O_2 = (\epsilon^\dagger \times \epsilon) \cdot (q \times k),
O_3 = (q \cdot \epsilon^\dagger)(q \cdot \epsilon), \quad O_4 = (k \cdot \epsilon^\dagger)(k \cdot \epsilon),
O_5 = (q \times \epsilon^\dagger) \cdot (q \times \epsilon), \quad O_6 = (k \times \epsilon^\dagger) \cdot (k \times \epsilon),
$$

with $q = p' - p$ the transferred momentum and $k = (p' + p)/2$ the average momentum.

Within the framework of chiral EFT, the potential up to the NLO in the paired $D_s D^*/D^*_s D$ system can be classified as the contact interaction, one-eta-exchange (OEE) and two-kaon-exchange (TKE) contributions. The contact potential $V_{\text{ct}}$ is parameterized order by order in power series of $q$ and $k$ as,

$$
V_{\text{ct}} = (C_0 + C_1 q^2 + C_2 k^2)O_1 + \sum_{i=2}^{6} C_{i+1}O_i + \ldots, \quad (3)
$$

where $C_i$ ($i = 0, \ldots, 7$) are the unknown low energy constants (LECs), and the ellipsis denotes the higher order terms.

The effective potentials arising from the OEE and TKE contributions can be extracted from the LO chiral Lagrangians,

$$
\mathcal{L} = i\langle \overline{\psi} \gamma^\mu [D_\mu + \Gamma_\mu] \psi \rangle + g\langle \overline{\psi} \gamma^\mu \gamma_5 u_\mu \psi \rangle
- i\langle \overline{\psi} [\nabla_\mu D_\mu] \psi \rangle + g\langle \overline{\psi} \gamma^\mu \gamma_5 u_\mu \psi \rangle, \quad (4)
$$

where the covariant derivative $D_\mu = \partial_\mu + \Gamma_\mu$. The $\mathcal{H}$ and $\mathcal{H}$ denote the superfields of the charmed and anticharmed mesons, respectively. One can consult Refs. [33, 35, 37] for their expressions. The axial coupling $g \simeq 0.57$ is extracted from the partial decay width of $D^{\ast+} \rightarrow D^0\pi^+$ [2]. The chiral connection $\Gamma_\mu$ and axial-vector current $u_\mu$ are formulated as

$$
\Gamma_\mu = \frac{1}{2} \left[ \xi^\dagger, \partial_\mu \xi \right], \quad u_\mu = \frac{i}{2} \left[ \xi^\dagger, \partial_\mu \xi \right], \quad (5)
$$

where $\xi^2 = U = \exp (i\phi/\sqrt{2})$, with $\phi$ the normally used matrix form of the light Goldstone octet [33], and the decay constants $f_K = 113$ and $f_{\eta} = 116$ MeV, respectively.

Now, the quantum number $I^G(J^{PC}) = 1^+(1^-)$ for the $Z_c$ state is favored [2] ($C$ parity for the neutral one). The $J^{PC}$ quantum number of the $Z_{cs}$ is undetermined, but $J^{PC} = \frac{1}{2} (1^-)$ is presumably used in most works [1, 3, 4, 6]. Under this assumption, the flavor wave function of the $Z_{cs}$ reads [3]

$$
|Z_{cs}^-\rangle = \frac{1}{\sqrt{2}} \left( |D_{cs}^- D^0 \rangle + |D_{cs}^- D^0 \rangle \right), \quad (6)
$$

One can easily get the OEE potential,

$$
V_{\text{OEE}} = -\frac{g^2}{6\sqrt{2}} \frac{O_4}{q^2 + m_\eta^2}, \quad (7)
$$

where $m_\eta$ is the $\eta$ meson mass, and $q^2 = p'^2 + p'^2 - 2pp' \cos \vartheta$ ($p = |p|$, $p' = |p'|$, and $\vartheta$ is the scattering angle in the c.m.s of VP).

The TKE potential from the loop diagrams (see Ref. [15] for the involved loop diagrams, and Refs. [31, 37] for the calculation details) can be simplified into a compact form in the heavy quark limit and SU(3)$_f$ limit,

$$
V_{\text{TKE}} = V_1 O_1, \quad (8)
$$

with

$$
V_1 = - \frac{24(4g^2 + 1)m_K^2 + (38g^2 + 5)q^2}{2304\pi^2 f_K^2}
+ \frac{6(6g^2 + 1)m_K^2 + (10g^2 + 1)q^2}{768\pi^2 f_K^2} \ln \frac{m_K^2}{(4\pi f_K)^2}
+ \frac{4(4g^2 + 1)m_K^2 + (10g^2 + 1)q^2}{384\pi^2 f_K^2} \varpi \arctan \frac{y}{\varpi}, \quad (9)
$$

where $\varpi = \sqrt{q^2 + 4m_K^2}$, and $y = \sqrt{2pp' \cos \vartheta - p^2 - p'^2}$. This result is obtained with the dimensional regularization, and the divergence is absorbed by the unrenormalized LECs introduced in Eq. (3).

The $Z_{cs}$ state is observed in the three-body decay of $e^+ e^- \rightarrow \gamma^\ast \rightarrow K^+ (D_s^0 D^0 + D_s^+ D^0)$. By fitting the line shape of the $K^+$ recoil-mass spectrum, we can extract the resonance parameters and pin down the inner structure of this state. The reaction is illustrated in Fig. 1, where the diagrams 1(a) and 1(b) depict the direct production and rescattering effect, respectively. The rescattering in Fig. 1(b) can generate the $Z_{cs}$ state dynamically. Additionally, we construct the following effective Lagrangians to mimic the $\gamma^\ast \rightarrow K_{VP}$ coupling vertex,

$$
\mathcal{L}_{\gamma^\ast \psi VP} = g_\gamma F^{\mu\nu} \left[ (\overline{P}_\mu u_\nu P^\dagger - \overline{P}^\dagger u_\nu P^\mu) + H.c. \right], \quad (10)
$$

where $g_\gamma$ denotes the effective coupling constant, and $F^{\mu\nu}$ is the field strength tensor of the virtual photon. $\overline{P}_\mu / P^\mu$ denote the (anti)charmed vector/pseudoscalar meson fields (e.g., see Ref. [33]). $u_\mu$ is the axial-vector field defined in Eq. (5).

**FIG. 1.** Diagrams (a) and (b) describe the direct production and rescattering contribution, respectively. The wiggly, thick, thin and dashed lines denote the virtual photon, vector meson, pseudoscalar meson and kaon, respectively. The gray circle with cross stands for the effective $\gamma^\ast \rightarrow K_{VP}$ coupling, while the gray box in diagram (b) signifies the rescattering $T$ matrix of the VP system.

With the above effective potentials, the $K_{VP}$ production amplitude $U(E, p)$ can be obtained by solving the following
Lippmann-Schwinger equation (LSE),
\[ \mathcal{U}(E, p) = \mathcal{M}(E, p) + \int \frac{d^3q}{(2\pi)^3} \mathcal{V}(E, p, q) G(E, q) \mathcal{U}(E, q), \]
(11)
where \( \mathcal{M}(E, p) \) represents the direct production amplitude of \( \gamma^* \to K\psi \) described in Eq. (10), \( E \) is the invariant mass of the VP pair. The two-body propagator \( G(E, q) \) of the intermediate state is given as
\[ G(E, q) = \frac{2\mu}{p^2 - q^2 + i\epsilon}, \quad |p| = \sqrt{2\mu(E - m_{\text{th}})}, \]
with \( \mu \) and \( m_{\text{th}} \) the reduced mass and threshold of the VP system, respectively. In the calculation, we introduce the Gaussian form factor \( \exp(-p^2/\Lambda^2 - q^2/\Lambda^2) \) (where \( \Lambda \) is the cutoff parameter) to avoid heavily involving the ultraviolet contributions [24, 28, 36].

The LSE of Eq. (11) is a three dimension integral equation, which can be reduced to one dimension through the partial wave decomposition. For example, the effective potentials in Eqs. (3) and (7)-(9) can be projected into the \( \ell s j \) basis (where \( \ell, s \) and \( j \) represent the orbital angular momentum, total spin and total angular momentum of the VP system, respectively) via [38]
\[ \mathcal{V}_{\ell,\ell'} = \int d\tilde{p} \int d\tilde{p}' \sum_{m,\ell,-m} \langle \ell', m; s, m_j - m_{\ell'}|j, m_j \rangle \times \sum_{m=-\ell}^{\ell} \langle \ell, m; s, m_j - m_{\ell}|j, m_j \rangle \mathcal{V}_{\ell m, \ell' m'}(\theta, \phi) \times \mathcal{Y}_{\ell m}(\theta, \phi) |s, m_j - m_{\ell}| V|s, m_j - m_{\ell'}, \]
(13)
with \( \mathcal{Y}_{\ell m} \) the spherical harmonics. We have demonstrated that the \( S-D \) wave mixing effect is insignificant for the \( Z_{Q}^{(*)} \) states [15], so we only consider the \( S \)-wave interaction for the \( Z_{cs} \) state in this Letter. The contact interaction in the \( S \)-wave projection reads
\[ \mathcal{V}_{ct} = \tilde{C}_s + C_s (p^2 + p'^2), \]
(14)
where \( \tilde{C}_s \) and \( C_s \) are the so-called partial wave LECs. They are the linear combinations of the LECs introduced in Eq. (3).

The differential decay width for \( \gamma^* \to K\psi \) can be expressed in terms of the production amplitude in Eq. (11) as
\[ \frac{d\Gamma}{dE} = \frac{1}{12(\sqrt{s})^2(2\pi)^3} |\mathcal{U}(E)|^2 |k_1||k_2^*|, \]
(15)
where \( \sqrt{s} \) is the c.m.s energy of the \( e^+e^- \) collision. \( k_1 \) and \( k_2^* \) are the three momentum of the spectator \( K \) in the c.m.s of \( e^+e^- \) and the three momentum of \( P(V) \) in the c.m.s of VP, respectively.

We study the \( d\Gamma/dE \) distributions and extract the resonance parameters of the \( Z_{cs} \) state. The general procedure is to fit the \( K^+ \) recoil-mass spectrum measured by the BESIII Collaboration [1]. We essentially have three free parameters \( \tilde{C}_s, C_s \) and \( \Lambda \) that can be varied to match the \( K^+ \) recoil-mass spectrum. In our previous work [15], these three parameters are well fixed by fitting the \( D^0D^{*-} \) invariant mass distributions of the \( Z_{cs} \) state [39]. The double \( D \) tag technique is used in this experimental analysis, in which the background contribution is largely suppressed. When the values of LECs and cutoff in Ref. [15] are fed into the \( D^*_sD^{*0} \) systems, we find a sharp peak automatically emerges around 3.98 GeV in the \( D^*_s-D^{*0} \) invariant mass spectrum. The result is shown in Fig. 2, where the blue dashed line is the production contributions in Fig. 1. When the other incoherent contributions in experiments are added up, the total line shape can quantitatively describe the distributions of experimental events (the red solid line in Fig. 2 with \( \chi^2/\text{dof} \approx 0.67 \)). In other words, we can describe these two states in an uniform framework with the same set of parameters, which strongly supports that the \( Z_{cs} \) and \( Z_e \) states are partners in SU(3)\(_{\text{f}} \) symmetry. We have tried to re-fit the experimental data of Ref. [1], and find the result is very similar. The line shape is slightly shifted and the parameters have similar size but just with a little larger errors (with \( \chi^2/\text{dof} \approx 0.64 \)). So the outputs are given in terms of the fitted parameters of the \( Z_{cs} \) state in Ref. [15].

![Fig. 2](image-url)
icates that the χEFT in the hidden charm sector tends to be convergent. The peak lies above the $D_s^+D^0$ threshold, which corresponds to a pole of the production $\mathcal{U}$ matrix in the unphysical Riemann sheet. This can be conducted through analytical continuation of the Green’s function $\mathcal{G}$ defined in Eq. (12),

$$ \mathcal{G}^0(p + i\epsilon) \equiv \mathcal{G}^0(p + i\epsilon) - 2i\text{Im}\mathcal{G}^0(p + i\epsilon), \quad (16) $$

where $\mathcal{G}^a$ and $\mathcal{G}^0$ denote the Green’s function defined in the physical and unphysical Riemann sheets, respectively. The pole position $m - i\Gamma/2$ reads,

$$ (m, \Gamma) = (3982.4^{+4.8}_{-3.4}, 11.8^{+5.5}_{-5.2}) \text{ MeV}, \quad (17) $$

where the errors inherit from those of the fitted parameters in Ref. [15]. The mass and width are highly consistent with the experimental data [1]. Therefore, our studies strongly support the $Z_c$ and $Z_{cs}$ as the SU(3)$_f$ symmetry partners and the resonances generated from the $DD^*/DD^*$ and $D_sD^*/D_s^*D$ interactions, respectively.

In addition, the formations and decay properties of these resonances can be synchronously interpreted in the molecular configuration pictures (The compact tetraquarks do not necessarily require their masses reside very close to the threshold). The near-threshold production indicates the $V$ and $F(V)$ mesons move very slowly, which renders them have enough time to interact with each other. A strongly attractive interaction can confine two particles for infinite time, which corresponds to a stable bound state. If the attraction is not enough strong but with a barrier to trap two particles for a finite time, then a resonance with certain lifetime is generated. In contrast to the bound states, the resonances naturally decompose into their ingredients at the end of their lifetime, i.e., the elastic decay modes would contribute dominantly to the partial decay widths. Yet, the inelastic decays with final states of a heavy quarkonium and a light meson proceed via shorter distance interactions (with $r \sim 1/m_D$), which is generally suppressed and thus reacts with less probability. Thus the inelastic channels only contribute a small amount of the partial widths [11, 13].

We can adopt the same framework to predict the unobserved states in the $D_s^*D^*$ system as well as the $B_s^*B/B_sB^*$ and $B_s^*B^*$ systems in the hidden bottom sectors. The inputs for these systems come from the fitted parameters of the $Z_c'$, $Z_0$ and $Z'_0$ states in Ref. [15], respectively. The predictions are listed in Table I. We find that there indeed exists a resonance in the $D_s^*D^*$ system and two resonances in the $B_s^*B/B_sB^*$ and $B_s^*B^*$ systems, respectively. They lie around $5 \sim 7$ MeV above the corresponding thresholds, and their widths coincide with those of the observed partners. Including the observed $Z_Q^{(i)}$ states, we can establish a complete spectrum for the $1(1^+)$ and $1/2(1^+)$ charged heavy quarkoniumlike states. The spectrum is vividly illustrated in Fig. 3. These predicted states could be reconstructed at the corresponding open charm/bottom channels or the $J/\psi K$ and $\Upsilon(nS)K$ ($n = 1, 2$) final states, respectively. Hunting for these states would be an intriguing topic in future experiments.

FIG. 3. A complete spectrum of the charged charmoniumlike (left panel) and bottomoniumlike (right panel) states with strangeness $S = 0$ and $S = -1$, respectively. The blue solid lines and red bands denote the central values and range of errors of the masses, respectively. The observed and predicted states are marked with ‘†’ and boldface, respectively.

In summary, we have generalized the framework of χEFT to decode the nature of the newly observed exotic $Z_{cs}$ state by BESIII [1]. The proximity to the $D_sD^*/D_s^*D$ threshold and large similarity with $Z_c$ hint that this unusual state may be a cousin of the $Z_c$ in SU(3)$_f$ family. The interaction kernel of the $D_sD^*$ system is calculated up to the NLO, which incorporates the LO contact terms, OPE and the NLO contact terms and TKE. When the LECs and cutoff fitted from the $Z_c$ data are fed into the $Z_{cs}$, iterating the effective potential in LSE automatically generates a sharp peak near the $D_sD^*/D_s^*D$ threshold in the $D_sD^*$ invariant mass spectrum. The mass and width from the pole of the production $\mathcal{U}$ matrix is very consistent with the experimental data, and the distributions of events can also be well described. Our studies strongly support that the $Z_{cs}$ and $Z_c$ are partners in SU(3)$_f$ family, and they have the same dynamical origin. Inspired by the $Z_{cs}$ results, we also predict the resonance parameters of three unobserved states in the $D_s^*D^*$, $B_s^*B/B_sB^*$ and $B_s^*B^*$ systems. We have established a complete spectrum of the charged charmoniumlike and bottomoniumlike states. Looking for these predicted states in experiments would help us to understand the chiral dynamics, the manifestations of SU(3)$_f$ and heavy quark symmetries at the hadron levels, more deeply.
