Abstract

The strange vector form factors are evaluated in the range between $Q^2 = 0$ and $Q^2 = 1$ GeV$^2$ in the framework of the SU(3) chiral quark-soliton model (or semi-bosonized SU(3) Nambu-Jona-Lasinio model). The rotational $1/N_c$ and $m_s$ corrections are taken into account up to linear order. Taking care of a proper Yukawa-tail of the kaonic cloud, we get $\langle r^2 \rangle_s^{\text{Sachs}} = -0.095$ fm$^2$ and $\mu_s = -0.68 \mu_N$. The results are compared with several different models.

PACS: 12.40.-y, 14.20.Dh

Key words: Strange vector form factors, strange magnetic moments, strange electric charge radius, kaonic clouds, chiral quark-soliton model.

I. INTRODUCTION

The strangeness content of the nucleon has been under a great deal of discussions for well over a decade. A few years ago, the European Muon Collaboration (EMC) [1] measured the spin structure function of the proton in deep inelastic muon scattering and showed that there is an indication of a sizable strange quark contribution. This remarkable result has been confirmed by following experiments of the Spin Muon Collaboration (SMC) [2,3], E142 and E143 collaborations [4,5].

Another experiment conducted at Brookhaven [6] (BNL experiment 734) measuring the low-energy elastic neutrino-proton scattering came to the more or less same conclusion. Kaplan and Manohar [7] showed how elastic \( \nu p \) and \( ep \) scatterings can be used to extract not only the \( G_1 \) form factors of the \( U(1)_A \) current but also the \( F_2 \) form factors of the baryon number current and furthermore how the strange quark matrix elements \( \langle p|\bar{s}\gamma_\mu\gamma_5s|p\rangle \) and \( \langle p|\bar{s}\gamma_\mu s|p\rangle \) can be evaluated. Following these suggestions, Garvey et al. [8] reanalyzed the above-mentioned \( \nu p \) elastic scattering experiment and determined proton strange form factors in particular at \( Q^2 = 0 \), pointing out the shortcomings of the analysis done by Ref. [6]. The best fit of Ref. [8] with the smallest \( \chi^2 \) tells \( F_1^s = 0.53 \pm 0.70 \) and \( F_2^s = -0.40 \pm 0.72 \). By comparing the different \( Q^2 \) dependence of \( d\sigma/dQ^2(\nu p) \) to \( d\sigma/dQ^2(\bar{\nu}p) \), Garvey et al. favor \( F_1^s(Q^2) > 0 \) and \( F_2^s(Q^2) < 0 \). However, these form factors are experimentally unknown to date and have no stringent and concrete constraints on their \( Q^2 \)–dependence yet. There are various proposals and experiments in progress (see Refs. [19,20] for details). All these considerations lead to the conclusion that, in contrast to the naive quark model, it is of great importance to consider strange quarks in the nucleon seriously.

There have been several theoretical efforts to describe the strange form factors of the nucleon. The first attempt was performed by Jaffe [9]. Jaffe took advantage of Ref. [10], i.e. the pole fit analysis based on dispersion theory, and estimated the mean-square strange radius and magnetic moment of the nucleon:

\[
\langle r^2 \rangle_{\text{Dirac}} = 0.16 \pm 0.06 \text{ fm}^2, \quad \mu_s = -0.31 \pm 0.09 \mu_N.
\]

More recently, Hammer et al. [11] updated Jaffe’s pole-fit analysis of the strange vector form
factors, relying upon a new dispersion theoretic analysis of the nucleon electromagnetic form factors. In fact, Hammer et al. improved Jaffe’s prediction, giving \( \mu_s = -0.24 \pm 0.03 \mu_N \) and \( \langle r^2 \rangle_{\text{Dirac}} = 0.21 \pm 0.03 \text{ fm}^2 \). A noticeable point of the pole-fit analysis is that it has the different sign of the strange electric radius, compared with almost other models.

Another interesting approach is the kaon-loop calculation. The main idea of the kaon-loop calculation is that the strangeness content of the nucleon exists as a pair of \( K\Lambda \) or \( K\Sigma \) components. Koepf et al. \[12\] first evaluated \( \mu_s \) and \( \langle r^2 \rangle_{\text{Dirac}} \), considering the possible kaon loops relevant for the strange vector form factors. However, Ref. \[12\] failed to include seagull terms which are essential to satisfy the Ward-Takahashi identity in the vector current sector. Musolf et al. \[13\] added these seagull terms and obtained \( \mu_s = -(0.31 \rightarrow 0.40) \mu_N \) and \( \langle r^2 \rangle_{\text{Dirac}} = -(6.68 \rightarrow 6.90) \times 10^{-3} \text{ fm}^2 \). The prediction of \( \langle r^2 \rangle_{\text{Dirac}} \) in the kaon-loop calculation is found to be much smaller than the pole-fit analysis. To reconcile the conflict between the pole-fit analysis and the kaon-loop calculation, Refs. \[14,18\] suggested the combination of the vector meson dominance (VMD) and \( \omega - \phi \) mixing in the vector-isovector channel with the kaon-loop calculation. The value of \( \langle r^2 \rangle_{\text{Dirac}} \) in Ref. \[14\] appeared to be larger than that of the kaon-loop calculation but still conspicuously smaller than that of the pole-fit analysis: \( \langle r^2 \rangle_{\text{Dirac}} = -(2.42 \rightarrow 2.45) \times 10^{-2} \text{ fm}^2 \). Ref. \[18\] evaluated also the strange vector form factors and discussed to a great extent several different theoretical estimates.

The SU(3) Skyrme model with pseudoscalar mesons \[15\] and with vector mesons \[16\] estimated, respectively, \( \mu_s = -0.13, \mu_s = -0.05 \) and \( \langle r^2 \rangle_{\text{Dirac}} = -0.10 \text{ fm}^2, \langle r^2 \rangle_{\text{Dirac}} = 0.05 \text{ fm}^2 \). Most recently, Leinweber obtained \( \mu_s = -0.75 \pm 0.30 \mu_N \) which appears to be much larger than other models.

In this paper, we aim at investigating the strange vector form factors and related strange observables in the SU(3) chiral quark-soliton model (\( \chi \)QSM), often called semi-bosonized SU(3) Nambu-Jona-Lasinio model (NJL). The model is based on the interaction of quarks with Goldstone bosons and has been shown to be quite successful in reproducing static properties of the baryons such as mass splitting \[21,22\], axial constants \[23\] and magnetic moments \[24\] and their form factors \[25,26\]. In a recent review \[27\], one can easily see how
well the model describe the baryonic observables. In particular, since the strange vector form factors are deeply related to the electromagnetic form factors \cite{311} being well described in $\chi$QSM, it is quite interesting to study them in the same framework.

The strangeness content of the nucleon can be interpreted in terms of the $\Lambda K$- and $\Sigma K$-components \cite{12,13}. It implies that one need incorporate the kaonic cloud properly in order to calculate the strange vector form factor. In fact, the strange electric charge radius in a hedgehog model is proportional to the inverse of the kaon mass, which means that it is very sensitive to the tail of the kaonic cloud. Hence, it is of great significance to take care that the kaonic cloud has a proper Yukawa asymptotics in order to evaluate the strange vector form factors rightly. In this respect the present paper provides a clear improvement over the results of ref. \cite{27}. In a recent study on the kaonic effect on the neutron electric form factor \cite{28}, it was shown that even the calculation of the neutron electric form factor requires a proper kaon tail. In the same spirit, we expect that the kaonic cloud will have a decisive effect on the strange vector form factors.

The outline of the paper is as follows: Section II sketches the general formalism for obtaining the strange vector form factors in the framework of $\chi$QSM. Section III presents the corresponding results and discuss them. Section IV contains a summary and draws the conclusion of the present work.

II. GENERAL FORMALISM

In this section we briefly review the formalism of $\chi$QSM. Details can be found in ref. \cite{27}. We start with the low-energy partition function in Euclidean space given by the functional integral over pseudoscalar meson ($\pi^a$) and quark fields ($\psi$):

$$\begin{align*}
Z &= \int \mathcal{D}\psi \mathcal{D}\psi^\dagger \mathcal{D}\pi^a \exp \left( -\int d^4x \psi^\dagger iD\psi \right), \\
&= \int \mathcal{D}\pi^a \exp (-S_{eff}[\pi]),
\end{align*}$$

(1)

where $S_{eff}$ is the effective action.
\[ S_{\text{eff}}[\pi] = -\text{Sp}n\iD. \] (2)

\( iD \) represents the Dirac differential operator

\[ iD = \beta(-i\bar{\theta} + \hat{m} + MU^{\gamma_5}) \] (3)

with the pseudoscalar chiral field

\[ U^{\gamma_5} = \exp(i\pi^a\lambda^a\gamma_5) = \frac{1 + \gamma_5}{2}U + \frac{1 - \gamma_5}{2}U^\dagger. \] (4)

\( \hat{m} \) is the matrix of the current quark mass given by

\[ \hat{m} = \text{diag}(m_u, m_d, m_s) = m_0\mathbf{1} + m_8\lambda_8, \] (5)

where \( \lambda^a \) designate the usual Gell-Mann matrices normalized as \( \text{tr}(\lambda^a\lambda^b) = 2\delta^{ab} \). Here, we have assumed isospin symmetry \( (m_u = m_d) \). \( M \) stands for the dynamical quark mass arising from the spontaneous chiral symmetry breaking, which is in general momentum-dependent \[29\]. We regard \( M \) as a constant and introduce the proper-time regularization for convenience. The \( m_0 \) and \( m_8 \) in Eq. (5) are defined, respectively, by

\[ m_0 = \frac{m_u + m_d + m_s}{3}, \quad m_8 = \frac{m_u + m_d - 2m_s}{2\sqrt{3}}. \] (6)

The operator \( iD \) is expressed in Euclidean space in terms of the Euclidean time derivative \( \partial_\tau \) and the Dirac one-particle Hamiltonian \( H(U^{\gamma_5}) \)

\[ iD = \partial_\tau + H(U^{\gamma_5}) + \beta\hat{m} - \beta\bar{m}\mathbf{1} \] (7)

with

\[ H(U^{\gamma_5}) = \frac{\bar{\alpha} \cdot \nabla}{i} + \beta MU^{\gamma_5} + \beta\bar{m}\mathbf{1}. \] (8)

\( \bar{m} \) is introduced in such a way that it produces a correct Yukawa-type asymptotic behavior of the profile function. \( \beta \) and \( \bar{\alpha} \) are the well-known Dirac Hermitian matrices. The \( U \) is assumed to have a structure corresponding to the so-called trivial embedding of the SU(2)-hedgehog into SU(3):
\[
U = \begin{pmatrix}
U_0 & 0 \\
0 & 1
\end{pmatrix},
\]
with
\[
U_0 = \exp \left[ i \vec{n} \cdot \vec{P}(r) \right].
\] (10)

The profile function \( P(r) \) is determined numerically by solving the Euler-Lagrange equation corresponding to \( \frac{\delta S_{eff}}{\delta P(r)} = 0 \). This yields a self-consistent classical field \( U_0 \) and a set of single quark energies and corresponding states \( E_n \) and \( \Psi_n \). Note that the \( E_n \) and \( \Psi_n \) do not constitute the nucleon \( |N\rangle \) yet because the collective spin and isospin quantum numbers are missing. Those are obtained by the semiclassical quantization procedure, described below in the context of the strange form factors.

The information of the strange vector form factors in the nucleon is contained in the quark matrix elements as follows:
\[
\langle N'(p')|J^s_\mu|N(p)\rangle = \langle N'(p')|\bar{s}\gamma_\mu s|N(p)\rangle.
\] (11)

The strange Dirac form factors of the nucleon are defined by the matrix elements of the \( J^s_\mu \):
\[
\langle N'(p')|J^s_\mu|N(p)\rangle = \bar{u}_N(p') \left[ \gamma_\mu F_1^s(q^2) + i\sigma_{\mu\nu} \frac{q^\nu}{2M_N} F_2^s(q^2) \right] u_N(p),
\] (12)
where \( q^2 \) is the square of the four momentum transfer \( q^2 = -Q^2 \) with \( Q^2 > 0 \). \( M_N \) and \( u_N(p) \) stand for the nucleon mass and its spinor, respectively. The strange quark current \( J^s_\mu \) can be expressed in terms of the baryon current and the hypercharge current:
\[
J^s_\mu = \bar{s}\gamma_\mu s = J^B_\mu - J^Y_\mu = \bar{q}\gamma_\mu \hat{Q} s q,
\] (13)
where
\[
J^B_\mu = \frac{1}{N_c} \bar{q}\gamma_\mu q,
\]
\[
J^Y_\mu = \frac{1}{\sqrt{3}} \bar{q}\gamma_\mu \lambda_8 q
\]
\[
\hat{Q}_s = \frac{1}{N_c} - \frac{1}{\sqrt{3}} \lambda_8,
\] (14)
where \( N_c \) denotes the number of colors of the quark. \( \hat{Q}_s = \text{diag}(0, 0, 1) \) is called strangeness operator. We employ the non-standard sign convention used by Jaffe [9] for the strange current. The baryon and hypercharge currents are equal to the singlet and octet currents, respectively.

The strange Dirac form factors \( F_1^s \) and \( F_2^s \) can be written in terms of the strange Sachs form factors, \( G_E^s(Q^2) \) and \( G_M^s(Q^2) \):

\[
G_E^s(Q^2) = F_1^s(Q^2) - \frac{Q^2}{4M_N^2}F_2^s(Q^2)
\]
\[
G_M^s(Q^2) = F_1^s(Q^2) + F_2^s(Q^2).
\]

(15)

In the non–relativistic limit \( Q^2 \ll M_N^2 \), the Sachs-type form factors \( G_E^s(Q^2) \) and \( G_M^s(Q^2) \) are related to the time and space components of the strange current, respectively:

\[
\langle N'(p')|J_0^s(0)|N(p)\rangle = G^s_E(Q^2)
\]
\[
\langle N'(p')|J_t^s(0)|N(p)\rangle = \frac{1}{2M_N}G^s_M(Q^2)i\epsilon_{ijk}q^i\langle \lambda' |\sigma_k |\lambda \rangle,
\]

(16)

where \( \sigma_k \) stand for Pauli spin matrices. The \( |\lambda\rangle \) is the corresponding spin state of the nucleon. The matrix elements of the strange quark current can be related to a correlator:

\[
\langle N'(p')|\bar{s}\gamma_\mu s|N(p)\rangle \sim \langle 0|J_{N'}(\vec{x}, T/2)\bar{q}\gamma_\mu \hat{Q}_s q J_N^†(\vec{y}, -T/2)|0\rangle.
\]

(17)

The nucleon current \( J_N \) can be built from \( N_c \) quark fields

\[
J_N(x) = \frac{1}{N_c!}\epsilon_{i_1 \cdots i_{N_c}}\Gamma_{JJ_3TT_3Y}^{\alpha_1 \cdots \alpha_{N_c}}\psi_{\alpha_1 i_1}(x) \cdots \psi_{\alpha_{N_c} i_{N_c}}(x).
\]

(18)

\( \alpha_1 \cdots \alpha_{N_c} \) denote spin–flavor indices, while \( i_1 \cdots i_{N_c} \) designate color indices. The matrices \( \Gamma_{JJ_3TT_3Y}^{\alpha_1 \cdots \alpha_{N_c}} \) are taken to endow the corresponding current with the quantum numbers \( JJ_3TT_3Y \).

In our model, Eq. (17) is represented by the Euclidean functional integral with regard to quark and pseudo-Goldstone fields:

\[
\langle N'(p')|\bar{q}\gamma_\mu \hat{Q}_s q|N(p)\rangle = \frac{1}{Z} \lim_{T \to \infty} \exp \left( ip_4 T - ip'_4 T \right)
\]
\[
\times \int d^4x d^3y \exp \left( -ip' \cdot \vec{y} + ip \cdot \vec{x} \right) \int DU \int D\bar{\psi} \int D\psi \int D\bar{\psi}^\dagger
\]
\[
\times J_{N'}(\vec{y}, T/2)q^†(0)\beta\gamma_\mu \hat{Q}_s q(0)J_N^†(\vec{x}, -T/2)
\]
\[
\times \exp \left[ -\int d^4z \bar{\psi}^\dagger iD\psi \right],
\]

(19)
where $Z$ stands for the normalization factor which is expressed by the same functional integral but without the quark current operator $\bar{s}\gamma_\mu s$. Eq. (19) can be decomposed into valence and sea contributions:

$$\langle N'(p')|\bar{q}\gamma_\mu \hat{Q} s|N(p)\rangle = \langle N'(p')|\bar{q}\gamma_\mu \hat{Q} s|N(p)\rangle_{\text{val}} + \langle N'(p')|\bar{q}\gamma_\mu \hat{Q} s|N(p)\rangle_{\text{sea}}, \quad (20)$$

where

$$\langle N'(p')|V_\mu(0)|N(p)\rangle_{\text{val}} = \frac{1}{Z} \Gamma_{j j_s j'_s T T'_s \gamma Y_s} \Gamma_{j j_s j'_s T T'_s \gamma Y_s} \lim_{T \to \infty} \exp \left( ip_4 \frac{T}{2} - i p'_4 \frac{T}{2} \right) \times \int d^3 x d^3 y \exp \left( -i p' \cdot \vec{y} + i p \cdot \vec{x} \right) \times \int \mathcal{D}U \exp (-S_{\text{eff}}) \sum_{i=1}^{N_c} \beta_i \langle \vec{y}, T/2 | \gamma [\beta \gamma_\mu \hat{Q} s] \gamma \rangle \times \gamma \langle 0, t_z | \begin{array}{c} \beta \langle \vec{y}, T/2 | \gamma \rangle \end{array} \times \prod_{i \neq j} \beta_i \langle \vec{y}, T/2 | \gamma \rangle, \quad (21)$$

and

$$\langle N'(p')|V_\mu(0)|N(p)\rangle_{\text{sea}} = -\frac{N_c}{Z} \Gamma_{j j_s j'_s T T'_s \gamma Y_s} \Gamma_{j j_s j'_s T T'_s \gamma Y_s} \lim_{T \to \infty} \exp \left( ip_4 \frac{T}{2} - i p'_4 \frac{T}{2} \right) \times \int d^3 x d^3 y \exp \left( -i p' \cdot \vec{y} + i p \cdot \vec{x} \right) \times \int \mathcal{D}U \exp (-S_{\text{eff}}) \text{Tr}_{\gamma \lambda} \langle 0, t_z | \gamma \lambda [\beta \gamma_\mu \hat{Q} s] | 0, t_z \rangle \times \prod_{i=1}^{N_c} \beta_i \langle \vec{y}, T/2 | \gamma \rangle, \quad (22)$$

$S_{\text{eff}}$ is the effective chiral action expressed by

$$S_{\text{eff}} = -N_c \text{Sln} [\partial_\tau + H(U^\gamma) + \beta \hat{m} - \beta \hat{m} \mathbf{1}]. \quad (23)$$

In order to perform the collective quantization, we have to integrate Eqs. (21) and (22) over small oscillations of the pseudo-Goldstone field around the saddle point Eq. (19). This will not be done except for the zero modes. The corresponding fluctuations of the pion fields are not small and hence cannot be neglected. The zero modes are relevant to continuous symmetries in our problem. In particular, we have to take into account the translational zero modes properly in order to evaluate form factors, since the soliton is not invariant under translation and its translational invariance is restored only after integrating over the
translational zero modes. Explicitly, the zero modes are taken into account by considering a slowly rotating and translating hedgehog:

\[ \tilde{U}(\vec{x}, t) = A(t)U(\vec{x} - \vec{Z}(t))A^\dagger(t). \]  

\[ A(t) \text{ belongs to an SU}(3) \text{ unitary matrix.} \]

The Dirac operator \( \tilde{D} \) in Eq. (7) can be written as

\[ i\tilde{D} = \left( \partial_\tau + H(U^\gamma) + A^\dagger(t)A(t) - i\beta \vec{Z} \cdot \nabla + \beta A^\dagger(t)(\vec{m} - \vec{m}1)A(t) \right). \]  

The corresponding collective action is expressed by

\[ \tilde{S}_{eff} = -N_c\text{Sp} \ln \left[ \partial_\tau + H(U^\gamma) + A^\dagger(t)A(t) - i\beta \vec{Z} \cdot \nabla + \beta A^\dagger(t)(\vec{m} - \vec{m}1)A(t) \right] \]  

with the angular velocity

\[ A^\dagger(t)A(t) = i\Omega_E = \frac{1}{2}i\Omega_E^a\lambda^a \]  

and the velocity of the translational motion

\[ \vec{Z} = \frac{d}{dt}\vec{Z}. \]  

Hence, Eq. (21) and Eq. (22) can be written in terms of the rotated Dirac operator \( \tilde{D} \) and chiral effective action \( \tilde{S}_{eff} \). The functional integral over the pseudoscalar field \( U \) is replaced by the path integral which can be calculated in terms of the eigenstates of the Hamiltonian corresponding to the collective action and these Hamiltonians can be diagonalized in an exact manner.

We take into account the rotational \( 1/N_c \) and \( m_s \) corrections up to linear order:

\[ \frac{1}{i\tilde{D}} \simeq \frac{1}{\partial_\tau + H} + \frac{1}{\partial_\tau + H}(-i\Omega_E) \frac{1}{\partial_\tau + H} + \frac{1}{\partial_\tau + H}(-\beta A^\dagger[\vec{m} - \vec{m}1]A) \frac{1}{\partial_\tau + H}. \]  

When the mass corrections are considered, SU(3) symmetry is no more exact. Thus, the eigenfunctions of the collective Hamiltonian are neither in a pure octet nor in a pure decuplet but in mixed states with higher representations.
\[ |8, N\rangle = |8, N\rangle + c_{10} |10, N\rangle + c_{27} |27, N\rangle \]  

with

\[ c_{10} = \frac{\sqrt{5}}{15} (\sigma - r_1) I_2 m_s, \quad c_{27} = \frac{\sqrt{6}}{15} (3\sigma + r_1 - 4r_2) I_2 m_s. \]

The constant \( \sigma \) is related to the SU(2) \( \pi N \) sigma term \( \Sigma_{SU(2)} = 3/2 (m_u + m_d) \sigma \) and \( r_i \) designates \( K_i / I_i \), where \( K_i \) stand for the anomalous moments of inertia defined in Ref. [21].

Having carried out a lengthy manipulation (for details, see Ref. [27]), we arrive at our final expressions for the strange vector form factors. The Sachs strange electric form factor \( G^s_E \) is expressed as follows (see appendix A for detail):

\[ G^s_E(\bar{Q}^2) = \left( 1 - \langle D^{(8)}_{88} \rangle_N \right) B(Q^2) \]
\[ + \langle D^{(8)}_{8a} J_a \rangle_N \frac{2 I_1(Q^2)}{\sqrt{3} I_1} + \langle D^{(8)}_{8p} J_p \rangle_N \frac{2 I_2(Q^2)}{\sqrt{3} I_2} \]
\[ + 3 \left( m_0 - \bar{m} + \frac{m_8}{\sqrt{3}} \langle D^{(8)}_{88} \rangle_N \right) C(Q^2) \]
\[ - \langle D^{(8)}_{8d} D^{(8)}_{8a} \rangle_N \frac{4 m_8}{\sqrt{3} I_1} \left( I_1 K_1(\bar{Q}^2) - I_1(\bar{Q}^2) K_1 \right) \]
\[ - \langle D^{(8)}_{8p} D^{(8)}_{8p} \rangle_N \frac{4 m_8}{\sqrt{3} I_2} \left( I_2 K_2(\bar{Q}^2) - I_2(\bar{Q}^2) K_2 \right), \]  

(32)

\( I_i \) and \( K_i \) are the moments of inertia and anomalous moments of inertia [21], respectively, \( B, I_i, \) and \( K_i \) correspond to the baryon number, moments of inertia, and the anomalous moments of inertia at \( Q^2 = 0 \), respectively. From Eq.(32), we can easily see that at \( Q^2 = 0 \) the strange electric form factor \( G^s_E \) vanishes (note that \( C(Q^2 = 0) = 0 \)). Making use of the relation \( \sum_{a=1}^{8} D^{(8)}_{8a} J_a = -\sqrt{3} Y / 2 \) and \( J_s = -N_c / (2\sqrt{3}) \), we obtain \( G^s_E(Q^2 = 0) = B - Y = S \).

Since the net strangeness of the nucleon is zero, \( G^s_E \) at \( Q^2 = 0 \) must vanish. The final expression of the Sachs strange magnetic form factor is written (see appendix A for detail) by

\[ G^s_M(\bar{Q}^2) = \frac{M_N}{|\bar{Q}|} \left[ -\frac{\langle D^{(8)}_{88} \rangle_N}{\sqrt{3}} \left( Q_0(\bar{Q}^2) + \frac{Q_1(\bar{Q}^2)}{I_1} + \frac{Q_2(\bar{Q}^2)}{I_2} \right) \right] \]
\[ + \langle (D^{(8)}_{88} - 1) J_3 \rangle_N \frac{X_1(\bar{Q}^2)}{3 I_1} + \langle d_{3pq} D^{(8)}_{8p} J_q \rangle_N \frac{X_2(\bar{Q}^2)}{\sqrt{3} I_2} \]
\[ + 6(m_0 - \bar{m})\langle D_{83}^{(8)} \rangle_N \mathcal{M}_0(\bar{Q}^2) + 2\sqrt{3}m_8\langle D_{88}^{(8)} D_{83}^{(8)} \rangle_N \mathcal{M}_0(\bar{Q}^2) \]
\[ + m_0\langle D_{83}^{(8)} \rangle_N \left( 2 \mathcal{M}_1(\bar{Q}^2) - \frac{2}{\sqrt{3}}r_1 \mathcal{X}_1(\bar{Q}^2) \right) \]
\[ + m_8\langle D_{83}^{(8)} D_{88}^{(8)} \rangle_N \left( 2 \mathcal{M}_1(\bar{Q}^2) - \frac{2}{3}r_1 \mathcal{X}_1(\bar{Q}^2) \right) \]
\[ + \sqrt{3}m_8\langle d_{3pq} D_{8p}^{(8)} D_{8q}^{(8)} \rangle_N \delta_{pq} \left( 2 \mathcal{M}_2(\bar{Q}^2) - \frac{2}{3}r_2 \mathcal{X}_2(\bar{Q}^2) \right), \] (33)

**III. RESULTS AND DISCUSSIONS**

In order to evaluate Eqs. (32,33) numerically, we follow the Kahana-Ripka discretized basis method \[30\]. However, note that it is of great importance to use a reasonably large size of the box \(D \approx 10 \text{ fm}\) so as to get a numerically stable results. The present SU(3) \(\chi\)QSM (equivalent to SU(3) NJL on the chiral circle) contains four free parameters. Two of them are fixed in the meson sector by adjusting them to the pion mass, \(m_\pi = 139 \text{ MeV}\), the pion decay constant, \(f_\pi = 93 \text{ MeV}\), and the kaon mass, \(m_K = 496 \text{ MeV}\). As for the fourth parameter, \(i.e.\) the constituent mass \(M\) of up and down quarks, values around \(M = 420 \text{ MeV}\) have been used because they have turned out to be the most appropriate one for the description of nucleon observables and form factors (see ref. \[27\]). In fact, \(M = 420 \text{ MeV}\) is the preferred value, which is always used in this paper. For the description of the baryon sector, we choose the method of Blotz et al. \[21\] modified for a finite meson mass. The resulting strange current quark mass comes out around \(m_s = 180 \text{ MeV}\). In order to illustrate the effect of the \(m_s\) the calculations in the baryonic sector are performed with both \(m_s = 0\) and finite \(m_s\). One should note that a SU(3)-calculation with \(m_s = 0\) does not correspond to a SU(2) calculation, since the spaces, in which the collective quantization are performed, are different.

In the present calculation, the mass parameter \(\bar{m}\) plays a pivotal role, because it makes the solitonic profile \(P(r)\) of Eq.(10) incorporate the proper Yukawa-type tail:

\[ P(r) \sim \exp(-\mu r) \frac{1 + \mu r}{r^2}, \] (34)
where \( \mu \) denotes the meson mass suppressing the tail of the profile. In fact, \( \mu \) is related to the \( \bar{m} \) in a non-linear way whose details can be extracted from the meson expansion of ref. [28]. In the end it turns out that \( \bar{m} = (m_u + m_d)/2 \), the \( \mu \) becomes the pion mass \( m_\pi = 139 \) MeV, while \( \mu \) corresponds to the kaon mass \( m_K \simeq 490 \) MeV for the \( \bar{m} \simeq 75 \) MeV. Actually, since the hedgehog formalism forces us to have just one profile function and hence all mesonic fields to have the same Yukawa mass in the tail, one has to decide if one wants the pion tail or the kaon tail to be correct. For previous investigations of electromagnetic properties of the nucleon it was preferable to have a correct pion tail at the expense of a poor kaon tail and in this sense all calculations of ref. [27] have been performed. For the present investigation of the strange vector form factors it is more desirable to have a kaon tail with a Yukawa mass, \( \mu \), being equal to the kaon mass, \( m_K \), and hence we prefer in this paper \( \bar{m} \simeq 75 \) MeV corresponding to \( \mu = m_K \simeq 490 \) MeV. We know that the pion tail is now too short. However, we do not expect it to matter for the strange vector form factors. We give the results with \( \mu = m_\pi = 139 \) MeV for comparison. Figure 1 shows the strange electric form factor \( G_E^s(Q^2) \), as the constituent quark mass \( M \) is varied from 400 MeV to 450 MeV with \( m_s = 180 \) MeV. The strange electric form factor \( G_E^s \) decreases as \( M \) increases. Fig. 2 displays the effect of the \( m_s \) corrections on the \( G_E^s \). When they are turned off, the \( G_E^s \) becomes negative. At first glance, it seems surprising, compared to the results with \( \mu = m_\pi \) [27], though in Ref. [27] the \( m_s \) corrections turn out to be very large. However, replacing \( \mu = m_\pi \) by \( \mu = m_K \) leads to the fact that the leading-order contribution and rotational \( 1/N_c \) corrections are sizably reduced, while the \( m_s \) corrections are relatively not much weakened. As a result, the \( m_s \) corrections change the sign of the \( G_E^s \) as shown in Fig. 2. This raises the question whether higher than first order corrections in \( m_s \) are important. This question will be investigated in near future.

In Fig. 3 the effect of the kaonic cloud is well explained. The \( G_E^s \) with \( \mu = m_K \) is almost three times smaller than that with \( \mu = m_\pi \). This remarkable result is in line with the recent investigation of the kaonic effects on the neutron electric form factor [28]. These kaonic effects can be understood more explicitly by evaluating the strange electric radii.
The Sachs and Dirac mean-square strange radii are, respectively, defined by
\[
\langle r^2 \rangle_{Sachs}^{s} = -6 \frac{dG_{E}^{s}(Q^2)}{dQ^2} \bigg|_{Q^2=0}, \quad \langle r^2 \rangle_{Dirac}^{s} = -6 \frac{dF_{1}^{s}(Q^2)}{dQ^2} \bigg|_{Q^2=0}.
\] (35)
We obtain \( \langle r^2 \rangle_{Sachs}^{s} \bigg|_{\mu=m_{\pi}} = -3.5 \times 10^{-1} \text{ fm}^2 \) and \( \langle r^2 \rangle_{Dirac}^{s} \bigg|_{\mu=m_{K}} = -3.2 \times 10^{-1} \text{ fm}^2 \) with the pion tail, whereas we get \( \langle r^2 \rangle_{Sachs}^{s} \bigg|_{\mu=m_{K}} = -9.5 \times 10^{-2} \text{ fm}^2 \) and \( \langle r^2 \rangle_{Dirac}^{s} \bigg|_{\mu=m_{K}} = -5.0 \times 10^{-2} \text{ fm}^2 \). Again, we find that the case of \( \mu = m_{K} \) is three times smaller than that of \( \mu = m_{\pi} \). The mean-square strange radii depend on the meson mass \( \mu \) which suppresses the tail of the profile, i.e. \( \langle r^2 \rangle_{Sachs}^{s} \sim 1/\mu \). From such a behavior of the \( \langle r^2 \rangle_{Sachs}^{s} \), we can derive the relation
\[
\frac{\langle r^2 \rangle_{Sachs}^{s} \bigg|_{\mu=m_{\pi}}}{\langle r^2 \rangle_{Sachs}^{s} \bigg|_{\mu=m_{K}}} = \frac{m_{K}}{m_{\pi}} \approx 3.5.
\] (36)
Eq.(36) explains the decrease of the \( \langle r^2 \rangle_{s} \) with \( \mu = m_{K} \).

Fig. 4 illustrates the strange electric densities weighted with \( r^2 \). As expected from the above discussion, the kaonic cloud diminishes the strange electric density sizably.

Fig. 5 draws the strange magnetic form factor. In contrast to the \( G_{E}^{s} \), the \( G_{M}^{s} \) increases slowly with the increasing constituent quark mass apart from the small \( Q^2 \) region (below about \( Q^2 = 0.2 \text{ GeV}^2 \)). Fig. 6 shows that the \( m_{s} \) corrections has a small effect on the \( G_{M}^{s} \). It is very different from what we saw in the case of the \( G_{M}^{s} \). However, Eq.(36) explains why the \( m_{s} \) corrections are reduced by \( \mu = m_{K} \): The fourth term including \( (m_{0} - \bar{m}) \) becomes smaller on account of the large \( \bar{m} \).

Fig. 7 displays the effect of the kaonic cloud on the \( G_{M}^{s} \). With \( \mu \) increased to be \( m_{K} \), we find that the \( G_{M}^{s} \) is almost 50 % enhanced. Fig. 8 draws the corresponding magnetic densities weighted by \( r^2 \).

In table 1, the strange magnetic moments \( \mu_{s} \) and mean-square strange radii \( \langle r^2 \rangle_{s} \) are displayed as a function of \( M \) and \( m_{s} \) in the case of \( \mu = m_{K} \), while in table 2 the same in the case of \( \mu = m_{\pi} \). According to our philosophy the values of table 1 with \( \mu = m_{K} \) are the results of the present model. If one fixes the constituent quark mass \( M \) to a value of \( M = 420 \text{ MeV} \) then other baryonic properties such as the octet-decuplet mass splitting and
Various form factors are reproduced as well. Hence, we have $M = 420$ MeV as canonical value. In table 3, we have made a comparison for the $\mu_s$ and $\langle r^2 \rangle_{Sachs}^s$ between different models.

We want to take the occasion to comment on Ref. [33] which provides calculations for a correct pion tail and poor kaon tail, $\mu = m_\pi$. Though Ref. [33] seems to use in this case the same model as the present work, there are significant differences between these two papers. First, Weigel et al. [33] do not consider rotational $1/N_c$ corrections in contrast to the present paper. This has the immediate consequence that the magnetic moments of Weigel et al. are $\mu_p = 1.06 \mu_N$, $\mu_n = -0.69 \mu_N$ for the nucleon [1] whereas the present work (including those corrections) yields $\mu_p = 2.20 \mu_N$, $\mu_n = -1.59 \mu_N$ with a far better comparison with experiment ($\mu_p = 2.79 \mu_N$, $\mu_n = -1.91 \mu_N$). Furthermore, Weigel et al. regularize, besides the real part of the action, also the imaginary one. This meets problems in producing the anomaly structure and is hence avoided in the approach of the present work. In addition the calculation of Weigel et al. are not fully self-consistent but use some scaling approximations.

**IV. SUMMARY AND CONCLUSION**

In summary, we have calculated in the SU(3) chiral quark-soliton model ($\chi$QSM) often called the semibosonized SU(3) Nambu–Jona-Lasinio model, the strange electric and magnetic form factors of the nucleon, $G_E^s$ and $G_M^s$ including the strange magnetic moment $\mu_s$, and the mean-square strange radius $\langle r^2 \rangle_s$. The theory takes into account rotational $1/N_c$ corrections and linear $m_s$ corrections. Choosing the parameters of the model in such a way that the kaon cloud falls off with a Yukawa mass equal to the kaon mass, we have obtained $\mu_s = -0.68 \mu_N$, $\langle r^2 \rangle_{\text{Dirac}}^s = -0.051 \text{ fm}^2$ and $\langle r^2 \rangle_{\text{Sachs}}^s = -0.095 \text{ fm}^2$. The results have been compared with different other models.

---

1For this comparison, the constituent quark mass $M = 450$ MeV is chosen. In case of $M = 420$ MeV, we have obtained $\mu_p = 2.39 \mu_N$ and $\mu_n = -1.76 \mu_N$ [24].
There are several points where the present calculations leave room for further studies. Apparently the dependence of the form factors on the value of $m_s$ is quite noticeable and probably one has to go to higher orders in perturbation theory in $m_s$. Besides the strange vector form factors the strange axial form factors are also of great interest. Presently we are performing investigations to clarify these questions.

ACKNOWLEDGMENT

We would like to thank Chr.V. Christov, P.V. Pobylitsa, M.V. Polyakov and W. Broniowski for fruitful discussions and critical comments. This work has partly been supported by the BMBF, the DFG and the COSY–Project (Jülich).

APPENDIX A:

In this appendix, we present all formulae appearing in Eqs.(32,33).

\[ \mathcal{B}(Q^2) = \int d^3x \, j_0(Qr) \left[ \Psi_{val}^\dagger(x)\Psi_{val}(x) - \frac{1}{2} \sum_n \text{sgn}(E_n) \Psi_n^\dagger(x)\Psi_n(x) \right], \]

\[ \mathcal{C}(Q^2) = -\frac{2N_c}{3} \sum_{nm} \int d^3x \, j_0(Qr) \int d^3y \left[ \frac{\Psi_n^\dagger(y)\beta \Psi_{val}(y)\Psi_n^\dagger(x)\Psi_n(x)}{E_n - E_{val}} \right. \]

\[ + \frac{1}{2} R_M(E_n, E_m) \Psi_n^\dagger(y)\beta \Psi_m(y)\Psi_n^\dagger(x)\Psi_n(x) \right], \quad (A1) \]

\[ \mathcal{I}_1(Q^2) = \frac{N_c}{6} \sum_{n,m} \int d^3x \, j_0(Qr) \int d^3y \left[ \frac{\Psi_n^\dagger(x)\overline{\tau}\Psi_{val}(x) \cdot \Psi_n^\dagger(y)\overline{\tau}\Psi_n(y)}{E_n - E_{val}} \right. \]

\[ + \frac{1}{2} \Psi_n^\dagger(x)\overline{\tau}\Psi_m(x) \cdot \Psi_n^\dagger(y)\overline{\tau}\Psi_n(y) R_I(E_n, E_m) \right], \]

\[ \mathcal{I}_2(Q^2) = \frac{N_c}{6} \sum_{n,m^0} \int d^3x \, j_0(Qr) \int d^3y \left[ \frac{\Psi_{m^0}^\dagger(x)\Psi_{val}(x) \cdot \Psi_{m^0}^\dagger(y)\Psi_{m^0}(y)}{E_{m^0} - E_{val}} \right. \]

\[ + \frac{1}{2} \Psi_n^\dagger(x)\overline{\tau}\Psi_{m^0}(x) \cdot \Psi_n^\dagger(y)\overline{\tau}\Psi_n(y) R_{m^0}(E_n, E_{m^0}) \right], \]

\[ \mathcal{K}_1(Q^2) = \frac{N_c}{6} \sum_{n,m} \int d^3x \, j_0(Qr) \int d^3y \left[ \frac{\Psi_n^\dagger(x)\overline{\tau}\Psi_{val}(x) \cdot \Psi_n^\dagger(y)\beta \overline{\tau}\Psi_n(y)}{E_n - E_{val}} \right. \]

\[ + \frac{1}{2} \Psi_n^\dagger(x)\overline{\tau}\Psi_m(x) \cdot \Psi_n^\dagger(y)\beta \overline{\tau}\Psi_n(y) R_M(E_n, E_m) \right], \]
\[ K_2(\vec{Q}^2) = \frac{N_c}{6} \sum_{n,m^0} \int d^3x \ j_0(Qr) \int d^3y \left[ \frac{\Psi_{m^0}^\dagger(x)\Psi_{val}(x)\Psi_{val}(y)\beta\Psi_{m^0}(y)}{E_{m^0} - E_{val}} \right. \\
+ \left. \frac{1}{2} \Psi_n^\dagger(x)\Psi_{m^0}(x)\Psi_{m^0}^\dagger(y)\beta\Psi_n(y)\mathcal{R}_\mathcal{M}(E_n, E_{m^0}) \right] \] (A2)

with regularization functions

\[ \mathcal{R}_\mathcal{I}(E_n, E_m) = -\frac{1}{2\sqrt{\pi}} \int_0^\infty \frac{du}{\sqrt{u}} \phi(u; \Lambda_i) \left[ \frac{E_n e^{-uE_n^2} + E_m e^{-uE_m^2}}{E_n + E_m} + \frac{e^{-uE_n^2} - e^{-uE_m^2}}{u(E_n^2 - E_m^2)} \right], \]

\[ \mathcal{R}_\mathcal{M}(E_n, E_m) = \frac{1}{2} \frac{\text{sgn}(E_n) - \text{sgn}(E_m)}{E_n - E_m}. \] (A3)

\[ Q_0(\vec{Q}^2) = N_c \int d^3x j_1(qr) \left[ \Psi_{val}(x) \gamma_5 \{ \hat{r} \times \vec{\sigma} \} \cdot \vec{\tau} \Psi_{val}(x) \right. \\
- \left. \frac{1}{2} \sum_n \text{sgn}(E_n) \Psi_n^\dagger(x) \gamma_5 \{ \hat{r} \times \vec{\sigma} \} \cdot \vec{\tau} \Psi_n(x) \mathcal{R}(E_n) \right], \]

\[ Q_1(\vec{Q}^2) = \frac{iN_c}{2} \sum_n \int d^3x j_1(qr) \int d^3y \left[ \text{sgn}(E_n) \Psi_n^\dagger(x) \gamma_5 \{ \hat{r} \times \vec{\sigma} \} \cdot \vec{\tau} \Psi_{val}(x) \Psi_{val}^\dagger(y) \Psi_n(y) \right. \\
+ \left. \frac{1}{2} \sum_m \Psi_n^\dagger(x) \gamma_5 \{ \hat{r} \times \vec{\sigma} \} \cdot \vec{\tau} \Psi_m(x) \Psi_m^\dagger(y) \Psi_n(y) \mathcal{R}_\mathcal{Q}(E_n, E_m) \right], \]

\[ Q_2(\vec{Q}^2) = \frac{N_c}{2} \sum_{m^0} \int d^3x j_1(qr) \int d^3y \left[ \text{sgn}(E_{m^0}) \Psi_{m^0}^\dagger(x) \gamma_5 \{ \hat{r} \times \vec{\sigma} \} \cdot \vec{\tau} \Psi_{val}(x) \Psi_{val}^\dagger(y) \Psi_{m^0}(y) \right. \\
+ \left. \sum_n \Psi_n^\dagger(x) \gamma_5 \{ \hat{r} \times \vec{\sigma} \} \cdot \vec{\tau} \Psi_{m^0}(x) \Psi_n(y) \mathcal{R}_\mathcal{Q}(E_n, E_{m^0}) \right], \]

\[ X_1(\vec{Q}^2) = N_c \sum_n \int d^3x j_1(qr) \int d^3y \left[ \Psi_n^\dagger(x) \gamma_5 \{ \hat{r} \times \vec{\sigma} \} \cdot \vec{\tau} \Psi_{val}(x) \Psi_{val}^\dagger(y) \Psi_n(y) \right. \\
+ \left. \frac{1}{2} \sum_m \Psi_n^\dagger(x) \gamma_5 \{ \hat{r} \times \vec{\sigma} \} \Psi_m(x) \Psi_m^\dagger(y) \Psi_n(y) \mathcal{R}_\mathcal{M}(E_n, E_m) \right], \]

\[ X_2(\vec{Q}^2) = N_c \sum_{m^0} \int d^3x j_1(qr) \int d^3y \left[ \Psi_{m^0}^\dagger(x) \gamma_5 \{ \hat{r} \times \vec{\sigma} \} \cdot \vec{\tau} \Psi_{val}(x) \Psi_{val}^\dagger(y) \Psi_{m^0}(y) \right. \\
+ \left. \sum_n \Psi_n^\dagger(x) \gamma_5 \{ \hat{r} \times \vec{\sigma} \} \cdot \vec{\tau} \Psi_{m^0}(x) \Psi_n(y) \mathcal{R}_\mathcal{M}(E_n, E_{m^0}) \right], \]

\[ M_0(\vec{Q}^2) = \frac{N_c}{3} \sum_n \int d^3x j_1(qr) \int d^3y \left[ \Psi_n^\dagger(x) \gamma_5 \{ \hat{r} \times \vec{\sigma} \} \cdot \vec{\tau} \Psi_{m^0}(x) \Psi_{val}^\dagger(y) \beta \Psi_n(y) \right. \\
+ \left. \frac{1}{2} \sum_m \Psi_n^\dagger(x) \gamma_5 \{ \hat{r} \times \vec{\sigma} \} \cdot \vec{\tau} \Psi_m(x) \Psi_{m^0}(y) \beta \Psi_n(y) \mathcal{R}_\beta(E_n, E_m) \right], \]
\[ M_1(Q^2) = \frac{N_c}{3} \sum_n \int d^3 x j_1(qr) \int d^3 y \]
\[ \times \left[ \frac{\Psi_n^\dagger(x) \gamma_5 \{ \hat{r} \times \vec{\sigma} \} \Psi_{\text{val}}(x) \cdot \Psi_n^\dagger(y) \beta \bar{\Psi}_n(y)}{E_n - E_{\text{val}}} \right. \]
\[ + \left. \frac{1}{2} \sum_m \Psi_m^\dagger(x) \gamma_5 \{ \hat{r} \times \vec{\sigma} \} \Psi_m(x) \cdot \Psi_m^\dagger(y) \beta \bar{\Psi}_n(y) R_{\beta}(E_n, E_m) \right] , \]
\[ M_2(Q^2) = \frac{N_c}{3} \sum_{m^0} \int d^3 x j_1(qr) \int d^3 y \]
\[ \times \left[ \frac{\Psi_{m^0}^\dagger(x) \gamma_5 \{ \hat{r} \times \vec{\sigma} \} \cdot \bar{\Psi}_{m^0}(x) \Psi_{m^0}^\dagger(y) \beta \bar{\Psi}_m(y)}{E_{m^0} - E_{\text{val}}} \right. \]
\[ + \left. \sum_n \Psi_n^\dagger(x) \gamma_5 \{ \hat{r} \times \vec{\sigma} \} \cdot \bar{\Psi}_{m^0}(x) \Psi_n^\dagger(y) \beta \bar{\Psi}_m(y) R_{\beta}(E_n, E_m) \right] . \quad (A4) \]

The regularization functions for the \( G_M^a \) are

\[ R(E_n) = \int \frac{d u}{\sqrt{u}} \phi(u; \Lambda_i) |E_n| e^{-uE_n^2} , \]
\[ R_Q(E_n, E_m) = \frac{1}{2\pi} c_i \int_0^1 \frac{d \alpha}{\sqrt{\alpha(1-\alpha)}} \alpha^\frac{1}{2} \alpha^{E_n^2 + (1-\alpha)E_m^2} \]
\[ \exp \left( -[\alpha E_n^2 + (1-\alpha)E_m^2]/\Lambda_i^2 \right) \],
\[ R_{\beta}(E_n, E_m) = \frac{1}{2\sqrt{\pi}} \int_0^\infty \frac{d u}{\sqrt{u}} \phi(u; \Lambda_i) \left[ E_n e^{-uE_n^2} - E_m e^{-uE_m^2} \right] . \quad (A5) \]

The cutoff parameter \( \phi(u; \Lambda_i) = \sum_i c_i \theta \left( u - \frac{1}{\Lambda_i} \right) \) is fixed by reproducing the pion decay constants and other mesonic properties \[27\].
TABLES

TABLE I. The strange magnetic moments and mean-square strange radius as varying the constituent quark mass. The kaon tail shows a Yukawa mass of $\mu = m_K \simeq 490$ MeV. Our final values are in this table with $M = 420$ MeV.

| $M$ | 400 MeV | 420 MeV | 450 MeV |
|-----|---------|---------|---------|
| $m_s$ [MeV] | 0 | 180 | 0 | 180 | 0 | 180 |
| $\mu_s [\mu_N]$ | -0.66 | -0.69 | -0.65 | -0.68 | -0.63 | -0.65 |
| $\langle r^2 \rangle_{\text{Dirac}}^{s} [\text{fm}^2]$ | 0.144 | -0.081 | 0.120 | -0.051 | 0.090 | -0.044 |
| $\langle r^2 \rangle_{\text{Sachs}}^{s} [\text{fm}^2]$ | 0.100 | -0.127 | 0.077 | -0.095 | 0.049 | -0.086 |

TABLE II. The strange magnetic moments and mean-square strange radius as varying the constituent quark mass. The pion tail shows a Yukawa mass of $\mu = m_\pi = 139$ MeV.

| $M$ | 400 MeV | 420 MeV | 450 MeV |
|-----|---------|---------|---------|
| $m_s$ [MeV] | 0 | 180 | 0 | 180 | 0 | 180 |
| $\mu_s [\mu_N]$ | -0.81 | -0.42 | -0.78 | -0.44 | -0.74 | -0.50 |
| $\langle r^2 \rangle_{\text{Dirac}}^{s} [\text{fm}^2]$ | -0.20 | -0.36 | -0.19 | -0.32 | -0.16 | -0.27 |
| $\langle r^2 \rangle_{\text{Sachs}}^{s} [\text{fm}^2]$ | -0.25 | -0.39 | -0.25 | -0.35 | -0.21 | -0.31 |
TABLE III. The theoretical comparison for the strange magnetic moment and mean-square strange radius between different models. \( M = 420 \text{ MeV}, \ m_s = 180 \text{ MeV}, \) and \( \mu = m_K \) are used for the present work.

Figure Captions

**Fig. 1**: The strange electric form factor $G_E^s$ as functions of $Q^2$ with the $\mu = m_K$: The solid curve corresponds to the constituent quark mass $M=420$ MeV, while dot-dashed curve draws $M=400$ MeV. The dashed curve displays the case of $M=450$ MeV. The $M=420$ MeV is distinguished since all other observables of the nucleon are then basically reproduced in this model.

**Fig. 2**: The strange electric form factor $G_E^s$ as functions of $Q^2$ with the $\mu = m_K$: The solid curve corresponds to the $m_s = 180$ MeV, while dashed curve draws $m_s = 180$ MeV. The constituent quark mass $M$ is 420 MeV.

**Fig. 3**: The strange electric form factor $G_E^s$ as functions of $Q^2$: The solid curve corresponds to the $\mu = m_K$, while dashed curve draws $\mu = m_\pi$. The constituent quark mass $M$ and $m_s$ are 420 MeV and 180 MeV, respectively.

**Fig. 4**: The strange electric density $r^2 \rho_E^s$ as functions of $r$: The solid curve corresponds to the $\mu = m_K$, while dashed curve draws $\mu = m_\pi$. The constituent quark mass $M$ and $m_s$ are 420 MeV and 180 MeV, respectively.

**Fig. 5**: The strange magnetic factor $G_M^s$ as functions of $Q^2$ with the $\mu = m_K$: The solid curve corresponds to the constituent quark mass $M=420$ MeV, while dot-dashed curve draws $M=400$ MeV. The dashed curve displays the case of $M=450$ MeV. The $M=420$ MeV is distinguished since all other observables of the nucleon are then basically reproduced in this model.

**Fig. 6**: The strange magnetic form factor $G_M^s$ as functions of $Q^2$ with the $\mu = m_K$: The solid curve corresponds to the $m_s = 180$ MeV, while dashed curve draws $m_s = 180$ MeV.
The constituent quark mass $M$ is 420 MeV.

**Fig. 7:** The strange magnetic form factor $G_M^s$ as functions of $Q^2$: The solid curve corresponds to the $\mu = m_K$, while dashed curve draws $\mu = m_{\pi}$. The constituent quark mass $M$ and $m_s$ are 420 MeV and 180 MeV, respectively.

**Fig. 8:** The strange magnetic density $r^2\rho_M^s$ as functions of $r$: The solid curve corresponds to the $\mu = m_K$, while dashed curve draws $\mu = m_{\pi}$. The constituent quark mass $M$ and $m_s$ are 420 MeV and 180 MeV, respectively.
