The Ellis semigroup of bijective substitutions

Johannes Kellendonk and Reem Yassawi

Abstract. For topological dynamical systems $(X, T, \sigma)$ with abelian group $T$, which admit an equicontinuous factor $\pi : (X, T, \sigma) \to (Y, T, \delta)$, the Ellis semigroup $E(X)$ is an extension of $Y$ by its subsemigroup $E^\text{fib}(X)$ of elements which preserve the fibres of $\pi$. We establish methods to compute $E^\text{fib}(X)$ and use them to determine the Ellis semigroup of dynamical systems arising from primitive aperiodic bijective substitutions. As an application, we show that for these substitution shifts, the virtual automorphism group is isomorphic to the classical automorphism group.

1. Introduction

Consider $(X, T, \sigma)$, the action $\sigma$ of an abelian group (or semigroup) $T$ by homeomorphisms on a compact metrisable space $X$. The Ellis semigroup $E(X)$ of $(X, T, \sigma)$ is the compactification of the group action in the topology of pointwise convergence on $X^X$. The study of its topological and algebraic structure, which was initiated by Ellis [12], reveals dynamical properties of $(X, T, \sigma)$ and is consequently an area of active study.

One topological property which has recently incited a lot of interest is tameness: $(X, T, \sigma)$ is tame if $E(X)$ is the sequential compactification of the action [15, 19], that is, each element of $E(X)$ is a limit of a sequence (as opposed to a limit of a net or generalised sequence) of homeomorphisms coming from the group action. This can be expressed purely using cardinality: $E(X)$ is tame if and only if its cardinality is at most that of the continuum [15]. Tameness implies, for instance, the following dynamical property [14, 16, 19]: if a compact metrisable minimal system which admits an invariant measure is tame, then it is a $\mu$-almost one to one extension of its maximal equicontinuous factor. Here $\mu$ is the unique ergodic probability measure on the maximal equicontinuous factor of $(X, T, \sigma)$, and $\mu$-almost one-to-one means that the set of points in the maximal equicontinuous factor which have a unique preimage under the factor map has full $\mu$-measure. As soon as all fibres of the maximal equicontinuous factor map contain more than one point, the system is thus not tame.

Systematic investigations focusing on the algebraic structure of $E(X)$ are, to our knowledge, restricted to the question of when $E(X)$ is a group, when it has a single minimal left ideal or, in the case of $T = \mathbb{Z}^+$, when its adherence subsemigroup is left simple. $E(X)$ is a group if and only if $(X, T, \sigma)$ is distal (proximality is trivial), $E(X)$ has a

Keywords. Ellis semigroup, substitution shifts.
single minimal left ideal if and only if proximality is transitive (see, for instance, [3]), and the adherence subsemigroup is left simple if and only if forward proximality implies forward asymptoticity [8]. Recently, a detailed computation of the Ellis semigroups of the dynamical systems arising from almost canonical projection method tilings [1, 2] has exhibited another algebraic structure which seems worthwhile investigating: namely the semigroups are all disjoint unions of groups. Semigroups which are disjoint unions of groups are precisely those which are completely regular, which means that every element admits a generalised inverse with which it commutes. Ellis semigroups associated to almost canonical projection method tilings are tame [1].

For the most part, good descriptions of Ellis semigroups are only currently available for tame systems. The present paper arose from a desire to obtain explicit algebraic descriptions of Ellis semigroups for a class of dynamical systems which are not tame. We study the Ellis semigroup of systems \((X_0, \mathbb{Z}, \sigma)\) arising from bijective substitutions \(\theta\). The fibres of the maximal equicontinuous factor map of such systems are never singletons and so the resulting semigroup is not tame. They also enjoy two properties which we harness. The first is that for these \(\mathbb{Z}\)-actions, forward and backward proximality are non-trivial and equal to forward and backward asymptoticity. We describe systems \((X, \mathbb{Z}, \sigma)\) with this property in Section 2.6, and show that their Ellis group \(E(X)\) is the disjoint union of the acting group \(\mathbb{Z}\) with its kernel \(M(X)\), that is, the smallest bilateral ideal of \(E(X)\); in particular, \(E(X)\) is completely regular. This reduces the task to the study of \(M(X)\).

The kernel \(M(X)\) of a compact subsemigroup of \(X^X\) is always completely simple and therefore can be described by the Rees–Suskevitch theorem and its topological extensions (Theorems 2.1, 2.4, and 2.5). This theorem characterises a completely simple semigroup as a matrix semigroup \(M[G; I, \Lambda; A]\), where \(G\) is the so-called structure group, \(I\) and \(\Lambda\) index the right and left ideals, respectively, and \(A\) is a matrix through which the semigroup operation is defined. Its entries are elements of \(G\) which specify the idempotents.

The second property that bijective substitution systems enjoy is that they are unique singular orbit systems. This means that they have exactly one orbit of singular fibres (fibres of the factor map on which proximality is non-trivial) over an equicontinuous factor. We study these systems in Section 3 in a way which can be summarised as follows. Given an equicontinuous factor \(\pi : (X, T, \sigma) \to (Y, T, \delta)\), we obtain a short exact sequence of right-topological semigroups for the Ellis semigroup which restricts to a short exact sequence of its kernel:

\[
E^{\text{fib}}(X) \hookrightarrow E(X) \xrightarrow{\pi} E(Y) \cong Y \quad \text{and} \quad M^{\text{fib}}(X) \hookrightarrow M(X) \xrightarrow{\pi} M(Y) \cong Y. \quad (1.1)
\]

Here \(E^{\text{fib}}(X)\) is the subsemigroup of functions which preserve the fibres of the factor map \(\pi\), and \(M^{\text{fib}}(X)\) is the kernel of \(E^{\text{fib}}(X)\). The two matrix semigroups associated to \(M^{\text{fib}}(X)\) and \(M(X)\) via the Rees–Suskevitch theorem are related (when properly normalised): they share the same \(I\), \(\Lambda\), and \(A\), and their corresponding structure groups form an exact sequence

\[
G^{\text{fib}} \hookrightarrow G \xrightarrow{\pi} Y, \quad (1.2)
\]
derived from the above (1.1). Finally, we make one further reduction: we restrict \( M_{fib}(X) \) to a singular fibre and obtain again a completely simple semigroup to which we can apply the Rees–Suskevitch theorem. If \( Y \) contains a single \( T \)-orbit, say that of \( y_0 \), such that \( \pi^{-1}(y_0) \) is singular, then the restriction of \( M_{fib}(X) \) to \( \pi^{-1}(y_0) \), denoted \( M_{fib}(X)_{y_0} \), has a matrix form which shares the same \( I, \Lambda \), and \( A \) as the other two matrix semigroups above. Furthermore, we show in Corollary 3.14 that if the singular fibres are finite and the idempotents generate \( M_{fib}(X)_{y_0} \), then the structure group \( G \) equals the infinite Cartesian product \( G_{\pi}/T \), where \( G_{\pi} \) is the structure group of \( M_{fib}(X)_{y_0} \), and \( Y/T \) is the space of \( T \)-orbits of \( Y \). We thus obtain a description of \( M(X) \) through the finite semigroup \( M_{fib}(X)_{y_0} \) and the extension (1.2). We prove that the extension is algebraically split so that \( G \) is a semidirect product of \( G_{fib} \) with \( Y \). While \( M_{fib}(X) \) is topologically isomorphic to its matrix semigroup representation, \( M(X) \) is only algebraically isomorphic to it.

The dynamical system \((X_\theta, \mathbb{Z}, \sigma)\) associated to a primitive aperiodic bijective substitution of length \( \ell \) has a natural equicontinuous factor, namely the adding machine \( \mathbb{Z}/\ell \mathbb{Z} \), and this isomorphism makes clear where the non-tameness comes from.

On the way to achieving this we also show that \( E_{fib}(X_\theta) \) is topologically isomorphic to

\[
E_{fib}(X_\theta) \cong \left( M[G_\theta; I_\theta, \Lambda; A] \cup \{1\}\right) \times \prod_{[z] \in \mathbb{Z}/\ell \mathbb{Z}} G_{\theta_0},
\]

and this isomorphism makes clear where the non-tameness comes from.

In general, \( \Gamma_\theta \) can be a proper subgroup of \( G_\theta \), but the quotient group \( G_\theta/\Gamma_\theta \) is always a cyclic group. We call its order \( h \) the generalised height of the substitution. \( h \) is at least as large as the classical height of a constant length substitution, and we give in Section 6 examples where it is strictly larger. It is related to the topological spectrum of the dynamical system which is given by the action of \( \mathbb{Z} \) on a minimal left ideal of \( E(X_\theta) \), and \( E(X_\theta) \) factors onto \( \mathbb{Z}/h\mathbb{Z} \). In other words, \( E(X_\theta) \) is a graded semigroup and its calculation can be reduced to its elements of degree 0. In the case of non-trivial generalised
height, our result is Theorem 4.22. Here, with the assumption that the generalised height equals the classical height, we are able to describe $E(X_\theta)$ algebraically in a similar way as in the trivial height case, but with the structure group $G_\theta$ replaced with $\tilde{\Gamma}_\theta$. However, when the generalised height is strictly larger than the classical height, the extension problem (1.2) remains unsolved.

In Section 5, we apply our machinery to partly answer a recent question of Auslander and Glasner in [4]. They define the notion of a semi-regular dynamical system, and ask whether a minimal, point distal shift which is not distal can be semi-regular. They show that the Thue–Morse shift is semi-regular. We extend their result, by showing in Corollary 5.11, that the shift generated by a primitive aperiodic bijective substitution is semi-regular. Implicitly, we relate the structure group $G_\theta$ to the virtual automorphism group that Auslander and Glasner define.

Our work is related to a recent work of Staynova [25], in which she computes the minimal idempotents of the Ellis semigroup for dynamical systems of bijective substitutions $\theta$ that are an AI extension of their maximal equicontinuous factor. In other words, $(X_\theta, \sigma)$ is an isometric extension, via $f : X_\theta \to X_\phi$, of a constant length substitution shift $(X_\phi, \sigma)$, which is in turn an almost one-to-one extension, via $\pi_{\text{max}} : X_\phi \to X_{\text{max}}$, of its maximal equicontinuous factor. Martin [22] characterises the bijective substitutions that are AI extensions of their maximal equicontinuous factor using a combinatorial property on the set of two-letter words allowed for $\theta$, namely that they are partitioned into sets according to what indices they appear at, as we scan all fixed points. Staynova uses the functoriality of the Ellis semigroup construction, namely that a map between dynamical systems induces a semigroup morphism between their Ellis semigroups, and the fact that the Ellis semigroup of an equicontinuous system is a group, thus having exactly one idempotent. Using Martin’s combinatorial condition, Staynova first computes the preimages of that idempotent in $E(X_\phi)$. Apart from the identity map, all preimages are minimal idempotents and live in the unique minimal left ideal. She then pulls this information up through the factor map $f$ to find that each of these minimal idempotents has two preimages, one for each minimal left ideal in $E(X_\theta)$.

Our work goes beyond the results of Staynova in several respects. First, our techniques apply to all bijective substitutions. Indeed, it is easy to define substitutions that do not satisfy Martin’s criterion, so that their dynamical systems are not AI extensions of their maximal equicontinuous factor (see Example 4.11). Second, we do not only determine the idempotents, but the complete algebraic structure of $E(X_\theta)$, at least if generalised height is not larger than classical height.

This paper is organised as follows. In Section 2, we provide the necessary background on semigroups and the Ellis semigroup of a dynamical system, and study $\mathbb{Z}$-actions for which forward and backward proximality implies forward and backward asymptoticity, respectively. In Section 3, we study the Ellis semigroup for dynamical systems which have a single orbit of singular fibres under an equicontinuous factor map. In Section 4, we study in detail the Ellis semigroup of a bijective substitution dynamical system, and give an algorithm that computes its structural semigroup. In Section 5, we apply our results
to investigate the virtual automorphism group of bijective substitution shifts. We end in Section 6 with some examples.

2. Preliminaries

The literature on the algebraic aspects of semigroups is vast and, although our work is partly based on now classical results from the forties, we provide some background to the reader who may not be familiar with the basic material. This can all be found in [18]. We then recall the basic definitions and results on the Ellis semigroup of topological dynamical systems. These can mostly be found in [3] or [17].

2.1. Semigroups, basic algebraic notions

A semigroup is a set $S$ with an associative binary operation, which we denote multiplicatively. Some of the semigroups in this paper have an identity element, but some do not. However, they will never have a 0-element.

A normal inverse to $s \in S$ is an element $t \in S$ such that $sts = s$, $tst = t$, and $st = ts$. A general element in a general semigroup need not admit a normal inverse, but if it exists, it is unique. We may therefore denote it by $s^{-1}$. A semigroup is called completely regular if every element admits a normal inverse. Completely regular semigroups have been studied in great detail [24]. They are exactly the semigroups which may be written as disjoint unions of groups, i.e., $S = \bigsqcup_i G_i$ such that multiplication restricted to $G_i$ defines a group structure [24, Theorem II.1.4]. The normal inverse of $s \in G_i$ is then its group inverse in $G_i$.

Of particular importance in the analysis of a semigroup are its idempotents and its ideals. An idempotent of a semigroup $S$ is an element $p \in S$ satisfying $pp = p$. The set of idempotents of $S$ is partially ordered via $p \leq q$ if $p = pq = qp$. An idempotent is called minimal if it is minimal w.r.t. the above order. In general, we cannot expect to have minimal idempotents.

A (left, right or bilateral) ideal of a semigroup $S$ is a nonempty subset $I \subseteq S$ satisfying $SI \subseteq I$, $IS \subseteq I$ or $SI \cup IS \subseteq I$, respectively. The different kinds of ideals will play different roles below. When we simply say ideal we always mean bilateral ideal. A semigroup is called simple if it does not have any proper ideal and left simple if it does not have any proper left ideal. Note that a left simple semigroup is simple. (Left, right or bilateral) ideals are ordered by inclusion. A minimal (left, right or bilateral) ideal is a minimal element w.r.t. this order; that is, a (left, right or bilateral) ideal is minimal if it does not properly contain another (left, right or bilateral) ideal. In general, we cannot expect to have minimal ideals, but their existence in our specific context will be guaranteed for by compactness, see below.

Whereas the intersection of two left ideals may be empty, this is not the case for the intersection of two bilateral ideals or the intersection of a left ideal with a bilateral ideal. Therefore either the intersection of all bilateral ideals of a semigroup $S$ is the unique minimal ideal of $S$, also called the kernel of $S$, or it is empty, in which case $S$ does not admit a minimal ideal. The kernel of a semigroup without 0-element is always simple [18].
Related to left and right ideals are the so-called Green’s equivalence relations. Two elements \(x, y \in S\) are \(L\)-related if they generate the same left ideal, that is, there are \(s, s' \in S\) such that \(x = sy\) and \(y = s'x\). Likewise, \(x, y \in S\) are \(R\)-related if they generate the same right ideal. The intersection of the \(L\)-relation with the \(R\)-relation is called the \(H\)-relation. The relation generated by the \(L\)-relation and the \(R\)-relation, that is the join of \(L\) and \(R\), is called the \(D\)-relation. The relations \(L\) and \(R\) commute, so \(x\) and \(y\) are \(D\)-related if there is a \(z\) such that \(x\) and \(z\) are \(L\)-related and \(z\) and \(y\) are \(R\)-related.

Two results are of importance for what follows: first, an \(H\)-class of \(S\) which contains an idempotent is a subgroup of \(S\) whose neutral element is the idempotent [18, Corollary 2.26], and second, two \(H\)-classes containing idempotents and which belong to a common \(D\)-class must be isomorphic as groups [18, Proposition 2.3.6].

### 2.2. Simple semigroups and the Rees matrix form

Let \(G\) be a group, let \(I\) and \(\Lambda\) be nonempty sets, and let \(A = (a_{\lambda i})_{\lambda \in \Lambda, \ i \in I}\) be a \(\Lambda \times I\) matrix with entries from \(G\). Then the matrix semigroup \(M[G; I, \Lambda; A]\) is the set \(I \times G \times \Lambda\) together with the multiplication

\[(i, g, \lambda)(j, h, \mu) = (i, ga_{\lambda j}h, \mu).\]

The matrix \(A\) is called the sandwich matrix and the group \(G\) is called the structure group.

It is an easy exercise to determine the idempotents and the left and the right ideals of \(M[G; I, \Lambda; A]\). Indeed, an idempotent is of the form

\[(i, a_{\lambda i}^{-1}, \lambda),\]

the left ideals are the sets \(I \times G \times \Lambda', \ \Lambda' \subset \Lambda\), and the right ideals are \(I' \times G \times \Lambda\), \(I' \subset I\). In particular, a completely simple semigroup has minimal left and minimal right ideals, namely those for which \(\Lambda'\) or \(I'\) contain a single element. These minimal left and right ideals are also the \(L\) and the \(R\) classes, and so the \(H\)-classes are of the form \(\{i\} \times G \times \{\lambda\}, \ \{i\} \times G \times \{\lambda\}\) is a subsemigroup of \(M[G; I, \Lambda; A]\) which is a group. The identity element of this group is the idempotent \((i, a_{\lambda i}^{-1}, \lambda)\). It is isomorphic to \(G\) via the isomorphism \((i, g, \lambda) \mapsto a_{\lambda i}g\). The normal inverse of \((i, g, \lambda)\) is \((i, a_{\lambda i}^{-1}g^{-1}a_{\lambda i}^{-1}, \lambda)\). In particular, a matrix semigroup as defined above is completely regular.

A completely simple semigroup is a simple semigroup which has minimal idempotents. We have the following characterisation of completely simple semigroups\(^1\).

**Theorem 2.1** (Rees–Suskevitch). A semigroup is completely simple if and only if it is isomorphic to a matrix semigroup \(M[G; I, \Lambda; A]\).

A proof of this theorem can be found in almost any textbook on semigroups. Since this result will be important in what follows, we give a partial sketch of how to construct a

---

\(^1\)Recall that we excluded the case that \(S\) has a 0-element. For semigroups with 0-element there is an analogous but slightly different characterisation [18].
Rees matrix form for a completely simple semigroup $S$. Proofs can be found in [18]. $S$ can be partitioned into its $R$-classes, which we index by a set $I$. It can also be partitioned into its $L$-classes, which we index by $\Lambda$. These partitions intersect yielding a partition into $H$-classes. It can be shown that if $S$ is simple and contains an idempotent, then it consists of a single $D$-class and that all its $H$-classes contain an idempotent. In particular, $S$ is a disjoint union of groups which are all isomorphic. Moreover, each $R$-class is a minimal right ideal and each $L$-class is a minimal left ideal so that each $H$-class is the intersection of a minimal right ideal with a minimal left one. Up to here, everything is canonical. But now we choose a minimal right ideal $R_{i_0}$ and a minimal left ideal $L_{\lambda_0}$ and set

$$G := H_{i_0\lambda_0},$$

where we use the notation $H_{i\lambda} = R_i \cap L_\lambda$. As mentioned above, all other $H$-classes are isomorphic to $G$, and indeed, given any $r_i \in H_{i\lambda_0}$ and $q_\lambda \in H_{i_0\lambda}$,

$$H_{i_0\lambda_0} \ni x \mapsto r_i x \in H_{i\lambda_0}, \quad (2.1)$$

$$H_{i_0\lambda_0} \ni x \mapsto xq_\lambda \in H_{i_0\lambda}, \quad (2.2)$$

are bijections which are group isomorphisms if $r_i$ and $q_\lambda$ are idempotents. Now the isomorphism between $G$ and the other $H_{i\lambda}$ will follow from the fact that $L$ commutes with $R$. Taking into account these choices define the matrix $A = (a_{\lambda i})$ through

$$a_{\lambda i} = q_\lambda r_i.$$

Then a direct calculation shows that

$$M(G; I, \Lambda; A) \ni (i, g, \lambda) \mapsto r_i g q_\lambda \in S$$

yields the desired isomorphism.

We must ask how the Rees matrix form of a completely simple semigroup depends on the choices. The first choice is that of the right and left ideals indexed by $i_0$ and $\lambda_0$; it defines the structure group $G = H_{i_0\lambda_0}$. A different choice will lead to a different but isomorphic structure group. An isomorphism can always be constructed using (2.1) and (2.2). The second choice is that of the elements $r_i$ and $q_\lambda$. It affects the sandwich matrix. Indeed, one has the freedom to multiply any row of $A$ from the left and, independently, any column of $A$ from the right by an element of $G$ to obtain a sandwich matrix which defines an isomorphic semigroup. It is therefore possible to normalise $A$ in such a way that one of its rows and one of its columns contains only the identity element of $G$. More precisely, having chosen the right and left ideals indexed by $i_0$ and $\lambda_0$, we can always bring $A$ into its so-called normalised form by taking $r_i$ to be the unique idempotent of $H_{i_0\lambda_0}$ and $q_\lambda$ to be the unique idempotent of $H_{i_0\lambda}$ [18, Theorem 3.4.2]. Up to the choice of $i_0$ and $\lambda_0$, this normalised Rees matrix form is then unique. Since any pair $(i, \lambda) \in I \times \Lambda$ determines a unique idempotent of $S$, we can also formulate this as follows: once we have chosen an idempotent of $S$, typically denoted by $e$, we obtain a unique normalised Rees matrix form.
for $S$. To be precise, we call this the normalised Rees matrix form for $S$ w.r.t. $e$. In what follows the use of $e$ refers to this chosen minimal idempotent.

Given a normalised matrix semigroup $M(G; I, \Lambda; A)$ w.r.t. $e$, we call the subgroup $\Gamma$ of $G$ generated by the coefficients $a_{\lambda i}$ of $A$ the little structure group.

**Lemma 2.2.** Consider a normalised matrix semigroup $M(G; I, \Lambda; A)$ w.r.t. $e = (i_0, 1, \lambda_0)$. The subsemigroup of $M(G; I, \Lambda; A)$ which is generated by the idempotents is equal to $M(\Gamma; I, \Lambda; A)$.

**Proof.** Let $K$ be the subsemigroup of $M(G; I, \Lambda; A)$ which is generated by the idempotents. By definition of the little structure group, $(i, G, \lambda) \cap K \subset (i, \Gamma, \lambda)$. Normalisation implies $a_{\lambda i} = 1$ provided that $i = i_0$ or $\lambda = \lambda_0$. Given $a_{\lambda i}$, we know that $(i, a_{\lambda i}^{-1}, \lambda)$ is an idempotent. Hence

$$(i_0, a_{\lambda i}, \lambda_0) = (i_0, 1, \lambda)(i, a_{\lambda i}^{-1}, \lambda)(i, 1, \lambda_0) \in (i_0, G, \lambda_0) \cap K.$$ 

This shows that $(i_0, \Gamma, \lambda_0) \subset (i_0, G, \lambda_0) \cap K$. Hence also

$$(i, \Gamma, \lambda) = (i, 1, \lambda_0)(i_0, \Gamma, \lambda_0)(i_0, 1, \lambda) \subset (i, G, \lambda) \cap K.$$ 

This shows that $M(G; I, \Lambda; A) \cap K = M(\Gamma; I, \Lambda; A)$. 

**2.2.1. Example.** We consider a class of matrix semigroups $M[G; I, \{\pm\}; A]$ which will play a major role later. For this family, $G$ is a finite group with neutral element $1$ and $I \subseteq G$ is a subset which generates $G$. Fix $g_0 \in I$. Let $\Lambda = \{+, -\}$ be a set of two elements. Define the $\Lambda \times I$ matrix $A = (a_{\lambda i})_{\lambda i}$ by

$$a_{+g} = 1, \quad a_{-g} = g_0 g^{-1}. \quad (2.3)$$ 

Then $M[G; I, \{\pm\}; A]$ has $2|I||G|$ elements of which $2|I|$ are idempotents. Note that $M[G; I, \{\pm\}; A]$ is normalised w.r.t. the idempotent $e = (g_0, 1, +)$.

**Lemma 2.3.** With the notation above, the little structure group of $M[G; I, \{\pm\}; A]$ is the group generated by $gh^{-1}$, $g, h \in I$.

**Proof.** This follows directly from $gh^{-1} = a_{-g}^{-1}a_{-h}$. 

**2.3. Compact semigroups**

A topological semigroup is a semigroup $S$ equipped with a topology in which the multiplication map $S \times S \rightarrow S$ is (jointly) continuous. A semigroup (equipped with a topology) is called right topological if, for any $s \in S$ right multiplication $\rho_s : S \rightarrow S$, $\rho_s(t) := ts$ is continuous. Note that this is equivalent to the multiplication $S \times S \rightarrow S$ being continuous in the left variable which is why the term left topological is also sometimes employed. We follow here the terminology of [17]. A topological semigroup is right topological and left topological (with the obvious definition), but the converse need not be true.
Let $X$ be a topological space. The set $F(X)$ of functions $X \to X$ with the topology of pointwise convergence is the same as the infinite Cartesian product $X^X$ with product topology. It is perhaps the simplest example of a right-topological semigroup, with the semigroup product being a composition of functions. If $X$ is compact, then $F(X)$ is compact. Only if $X$ is discrete is $F(X)$ a topological semigroup.

Let $\pi : X \to Y$ be a continuous surjection. We call the preimage $\pi^{-1}(y)$ the $\pi$-fibre of $y$. Let $F^{\text{fib}}(X) \subset F(X)$ be the subsemigroup of all functions $X \to X$ which preserve the $\pi$-fibres. Since fibres are closed subspaces of $X$, $F^{\text{fib}}(X)$ is a closed subsemigroup of $F(X)$. We can view $f \in F^{\text{fib}}(X)$ as a function $\tilde{f}$ on $Y$,

$$\tilde{f} : y \mapsto f|_{\pi^{-1}(y)},$$

which, evaluated at $y$, is the restriction of $f$ to $\pi^{-1}(y)$, $\tilde{f}(y)(x) = f(x)$ for $x \in \pi^{-1}(y)$. This identification $f \mapsto \tilde{f}$ yields a topological isomorphism, i.e., a homeomorphism which is also a semigroup isomorphism, between $F^{\text{fib}}(X)$ and the direct product $\prod_{y \in Y} F(\pi^{-1}(y))$, where the semigroup multiplication in the latter space is $\tilde{f}_1 \tilde{f}_2(y) = \tilde{f}_1(y) \circ \tilde{f}_2(y)$ and we equip it with the product topology, with $F(\pi^{-1}(y))$ still carrying the topology of pointwise convergence. Recall that $F(\pi^{-1}(y))$ is a topological semigroup if the fibre of $y$ is finite. By definition of the product topology we therefore get that $\prod_{y \in Y} F(\pi^{-1}(y))$ is a topological semigroup provided all fibres are finite.

For compact semigroups one has the following results concerning their kernels and corresponding Rees matrix form.

**Theorem 2.4.** Let $S$ be a compact right-topological semigroup. Then $S$ admits a kernel $\mathcal{M}(S)$ which contains all minimal idempotents, so that $\mathcal{M}(S)$ is isomorphic to a matrix semigroup. Furthermore, all minimal left ideals are compact and homeomorphic, and two $\mathcal{H}$-classes of $\mathcal{M}(S)$ which belong to the same minimal right ideal are topologically isomorphic.

This theorem is discussed in [17, Corollary 2.6 and Theorem 2.11]. The essential input from the compact topology is the existence of an idempotent and the continuity of the map (2.2). We mention that, in general, minimal right ideals are not closed, nor are $\mathcal{H}$-classes closed, nor are two $\mathcal{H}$-classes topologically isomorphic which do not belong to the same minimal right ideal. $\mathcal{M}(S)$ is then not topologically isomorphic to a matrix semigroup.

One consequence of Theorem 2.4 will be particularly important below, namely that for any minimal idempotent $p$ of a compact right-topological semigroup $S$, $pSp$ is a group. Indeed, the chain of inclusions

$$p\mathcal{M}(S)p \subset pSp = pSpp \subset p\mathcal{M}(S)p$$

shows that $pSp$ is isomorphic to the structure group of the kernel $\mathcal{M}(S)$.

If the multiplication of $S$ is jointly continuous, then the topological aspects of Theorem 2.4 can be strengthened. We can equip the normalised Rees matrix form $M[G; I, \Lambda; A]$ (w.r.t. $e = (i_0, 1, \lambda_0)$ of $\mathcal{M}(S)$ with the following topology: we identify $G$ with $H_{i_0} = eSe$, $I$ with the set of idempotents of $L_{\lambda_0}$, $\Lambda$ with the set of idempotents of $R_{i_0}$, and
we equip all these subsets of $S$ with the relative topology, and finally $I \times G \times \Lambda$ with the product topology. Under the assumption that $S$ is a compact topological semigroup, we have that $G$ is a compact topological group, $I$ and $\Lambda$ are compact subsets, and the semigroup product on $M[G; I, \Lambda; A]$ is jointly continuous.

**Theorem 2.5.** Let $S$ be a compact topological semigroup. Then $\mathcal{M}(S)$ is topologically isomorphic to the normalised matrix semigroup $M[G; I, \Lambda; A]$.

A proof of this theorem can be found in [9, Theorem 3.21]. As now also the map (2.1) is continuous, all $\mathcal{H}$-classes of $M(S)$ are closed and topologically isomorphic.

### 2.4. Extensions of groups by completely simple semigroups

We now use the above description of completely simple semigroups to study extensions

$$K \hookrightarrow S \xrightarrow{\pi} Y,$$

where $Y$ is a group with neutral element $y_0$, $S$ a semigroup, $\pi$ a semigroup epimorphism, and $K$ the kernel of $\pi$,

$$K = \{ s \in S : \pi(s) = y_0 \}.$$ 

$K$ is a subsemigroup of $S$ which is closed if $S$ and $Y$ are right topological and $\pi$ is continuous.

If $e \in S$ is an idempotent, then $\pi(e)$ must be an idempotent and hence equal to $y_0$ so that we obtain a restricted extension $eKe \hookrightarrow eSe \xrightarrow{\pi_e} Y$, where $\pi_e$ is the restriction of $\pi$ to $eSe$. If moreover $e$ is an idempotent in the kernel of $S$, then by (2.5), $eSe$ is a group, as is $eKe$, so that the restricted extension is an extension of groups.

A semigroup $S$ is **regular** if, for any $s \in S$, there exists $t \in S$ such that $s = sts$. Clearly, any completely regular semigroup is regular.

**Proposition 2.6.** Consider an extension $K \hookrightarrow S \xrightarrow{\pi} Y$ of a group $Y$ by a completely simple semigroup $K$, where $S$ is regular. Then $S$ is completely simple. If $K$ has normalised Rees matrix form $M[G; I, \Lambda; A]$ w.r.t. an idempotent $e$, then $S$ has normalised Rees matrix form $M[\mathcal{H}; I, \Lambda; A]$ w.r.t. $e$, where $\mathcal{H} = eSe$ is the extension of $Y$ by $G = eKe$ determined by the exact sequence of groups $eKe \hookrightarrow eSe \xrightarrow{\pi_e} Y$.

**Proof.** We first show that $S$ must be completely simple. Let $M \subset S$ be an ideal. Then $M \cap K$ is an ideal of $K$. As $K$ is simple, $M \cap K = K$. Thus $M$ contains all idempotents of $S$. Let $s \in S$ and $t \in S$ such that $s = sts$. Then $ts$ is an idempotent and so we see that $S \subset SK \subset SM \subset M$. Therefore $S$ is completely simple.

Let $M[\mathcal{H}; I, \Lambda; A]$ be the normalised Rees matrix form of $S$ w.r.t. $e$; in particular $\mathcal{H} = eSe$. Since $K$ contains the subsemigroup generated by the idempotents of $S$, by Lemma 2.2, the coefficients of $A$ belong to $G := eKe = \ker \pi_e$. Hence $M[G; I, \Lambda; A]$ is well defined and, with $e = (i_0, 1, \lambda_0)$ and $(i_0, 1, \lambda_0)(i, g, \lambda)(i_0, 1, \lambda_0) = (i_0, g, \lambda_0)$, we obtain

$$\pi(i, g, \lambda) = \pi(i_0, g, \lambda_0) = \pi_e(g)$$
so that $K = M[\ker \pi_e; I, \Lambda; A]$. Since the normalised Rees matrix form w.r.t. $e$ is unique, we see that $I, \Lambda,$ and $A$ are completely determined by $K$.

We will apply Proposition 2.6 to a situation in which $Y$ is a topological group and $K$ is a topological semigroup, but $S$ is only a right-topological semigroup. Therefore we cannot conclude that $S$ is topologically isomorphic to $M[\mathcal{G}; I, \Lambda; A]$. Indeed, the group $\mathcal{G} = eSe$ is only closed if the right ideal containing $e$ is closed, which we cannot expect. The interest in the above construction is therefore only algebraic. It is particularly useful if the group extension is split so that $\mathcal{G}$ is a semidirect product of $G$ with $Y$.

### 2.5. Ellis semigroup of a dynamical system

Given a dynamical system $(X, T, \sigma)$, the family of homeomorphisms $\{\sigma^t : t \in T\}$ is a subsemigroup of $F(X)$. Its closure, denoted by $E(X,T,\sigma)$, or simply $E(X)$ if the rest is understood, is still a semigroup, called the Ellis semigroup (or enveloping semigroup) of the dynamical system. Since $X$ is compact, the set of all functions $X \to X$ is compact in the topology of pointwise convergence and so $E(X,T,\sigma)$ is a compact right-topological semigroup, by construction.

The Ellis semigroup is closely related to the *proximity* relation. Given a metric $d$ on $X$ which generates the topology, two points $x, x'$ are proximal if $\inf_{t \in T} d(\sigma^t(x), \sigma^t(x')) = 0$. The proximal relation does not depend on the choice of metric (which generates the topology). Its relation with the Ellis semigroup is the following.

**Theorem 2.7** ([3, Chapter 3, Proposition 8]). Let $E(X)$ be the Ellis semigroup of a dynamical system $(X,T,\sigma)$. Two points $x$ and $y$ are proximal if and only if there exists $f \in E(X)$ such that $f(x) = f(y)$.

In particular, we see that, given any idempotent $p \in E(X)$ and $x \in X$, the points $p(x)$ and $x$ are proximal.

### 2.6. Complete regularity for $\mathbb{Z}$-actions

In this section, we give a sufficient condition on a $\mathbb{Z}$-action so that its Ellis semigroup $E(X, \mathbb{Z})$ is completely regular. We will see below that it is satisfied by the dynamical systems defined by bijective substitutions.

Since the union of the closure of two sets is the closure of their union, we can decompose

$$E(X) = E(X, \mathbb{Z}^+) \cup E(X, \mathbb{Z}^-),$$

where $E(X, \mathbb{Z}^\pm)$ is the closure of $\{\sigma^t : t \in \mathbb{Z}^\pm\}$. This allows us to compute the elements of $E(X)$ by looking independently, forward in “time”, and backwards in “time”.

We say that two points $x, x' \in X$ are forward proximal if

$$\inf_{t \in \mathbb{Z}^+} d(\sigma^t(x), \sigma^t(x')) = 0.$$
We say that two points \( x, x' \in X \) are forward asymptotic if

\[
\lim_{t \to +\infty} d(\sigma^t(x), \sigma^t(x')) = 0.
\]

Similarly, we define backward proximality and asymptoticity using \( \sigma^{-1} \) in place of \( \sigma \). Clearly, sequences which are forward asymptotic are forward proximal. The following lemma is related to the work of [8] in which the adherence semigroup of a \( \mathbb{Z}^+ \)-action is defined and analysed.

**Lemma 2.8.** Let \((X, \sigma)\) be a dynamical system for which forward proximality agrees with forward asymptoticity. Then \( E(X, \mathbb{Z}^+) \) has a unique minimal left ideal \( \mathcal{M}(X, \mathbb{Z}^+) \) and contains besides this ideal only \( \mathbb{Z}^+ \).

**Proof.** An element \( f \in E(X, \mathbb{Z}^+) \setminus \mathbb{Z}^+ \) is the limit of a generalised sequence \((\sigma^{t_v})_v\), \( t_v \in \mathbb{Z}^+ \) which is not in \( \mathbb{Z}^+ \). Hence the generalised sequence \((t_v)_v\) has the property that for any finite \( N \in \mathbb{Z}^+ \) there exists \( v_0 \) such that \( t_v \geq N \) for all \( v > v_0 \). In particular, if \( x \) and \( y \) are forward asymptotic points, then \( \lim_v d(\sigma^v(x), \sigma^v(y)) = 0 \), and hence \( f(x) = f(y) \).

\( E(X, \mathbb{Z}^+) \) is also a compact right-topological semigroup and hence has minimal left ideals and minimal idempotents. Furthermore, \( x, y \in X \) are forward proximal if and only if there exists \( f \in E(X, \mathbb{Z}^+) \) such that \( f(x) = f(y) \). Let \( p \in E(X, \mathbb{Z}^+) \) be any idempotent. For any \( x \in X \), \( p(x) \) is forward proximal to \( x \) and, by our assumption therefore, forward asymptotic to \( x \). This implies that if \( f \in E(X, \mathbb{Z}^+) \setminus \mathbb{Z}^+ \), then \( f(p(x)) = f(x) \). Since \( x \) was arbitrary, we find \( f = fp \).

This identity shows that any \( f \in E(X, \mathbb{Z}^+) \setminus \mathbb{Z}^+ \) lies in the ideal generated by the idempotent \( p \). If \( p \) is minimal, then this ideal is a minimal left ideal. Since \( p \) can be any minimal idempotent, there can only be one minimal left ideal.

Note that the unique minimal left ideal \( \mathcal{M}(X, \mathbb{Z}^+) \) of the previous lemma is the kernel of \( E(X, \mathbb{Z}^+) \).

**Corollary 2.9.** Let \((X, \sigma)\) be a dynamical system for which forward proximality agrees with forward asymptoticity and backward proximality agrees with backward asymptoticity. Then \( E(X) \) is completely regular. If moreover the forward and the backward proximality relations are non-trivial (not diagonal), then \( E(X) \) is the disjoint union of its kernel \( \mathcal{M}(X) \) with the acting group \( \mathbb{Z} \).

**Proof.** Minimal left ideals which contain idempotents are completely simple and hence, by the Rees structure theorem, disjoint unions of groups. Therefore Lemma 2.8 implies that \( E(X, \mathbb{Z}^+) \setminus \mathbb{Z}^+ \) is completely regular. \( E(X) \) is thus a union of completely regular subsemigroups. Hence any element of \( E(X) \) has an inverse with which it commutes.

To proof the second statement we first show that \( \mathcal{M}(X, \mathbb{Z}^+) \) is a minimal left ideal in \( E(X) \). Let \( f \in E(X) \), \( g \in E(X, \mathbb{Z}^+) \setminus \mathbb{Z}^+ \). So \( f = \lim \sigma^{n_\mu} \) and \( g = \lim \sigma^{m_\mu} \), however with \( m_\mu \to +\infty \). Then \( fg = \lim_i \sigma^{n_\mu} g \). Since \( \sigma^{n_\mu} g = \lim_i \sigma^{n_\mu+m_\mu} \in E(X, \mathbb{Z}^+) \) and \( E(X, \mathbb{Z}^+) \) is closed, we have \( fg \in E(X, \mathbb{Z}^+) \). Suppose that \( fg = \sigma^n \) for some \( n \in \mathbb{Z} \). As \( g \in \mathcal{M}(X, \mathbb{Z}^+) \), we have \( gp = g \) for some idempotent \( p \in \mathcal{M}(X, \mathbb{Z}^+) \). It follows that
1 = σ⁻ⁿ fg = σ⁻ⁿ fgp = p. This implies that \( E(X, \mathbb{Z}^+) \) is a group and thus contradicts the assumption that the forward proximality relation is non-trivial [3]. Hence \( fg \notin \mathbb{Z} \) so that, by Lemma 2.8, \( E(X) \mathcal{M}(X, \mathbb{Z}^+) \subset \mathcal{M}(X, \mathbb{Z}^+) \) and moreover \( \mathcal{M}(X, \mathbb{Z}^+) \cap \mathbb{Z} = \emptyset \). To show minimality of \( \mathcal{M}(X, \mathbb{Z}^+) \) it suffices to show that all idempotents of \( \mathcal{M}(X, \mathbb{Z}^+) \) are minimal in \( E(X) \). Let \( q \in \mathcal{M}(X, \mathbb{Z}^+) \) and \( p \in E(X) \) be idempotents such that \( p \leq q \). This means that \( pq = qp = p \). As we just showed, \( p = pq \in \mathcal{M}(X, \mathbb{Z}^+) \). But then \( p = q \) as \( q \) is minimal in \( E(X, \mathbb{Z}^+) \).

As the kernel of a semigroup is the union of its minimal left ideals, we now have shown that \( \mathcal{M}(X) = \mathcal{M}(X, \mathbb{Z}^+) \cup \mathcal{M}(X, \mathbb{Z}^-) \) and that \( \mathcal{M}(X) \cap \mathbb{Z} = \emptyset \).

The arguments in the second part of the proof were adapted from [7], where it is also shown that, for minimal \( \mathbb{Z} \)-actions on totally disconnected compact metric spaces, the condition that forward proximality agrees with forward asymptoticity and backward proximality agrees with backward asymptoticity is also necessary for complete regularity.

### 2.7. Equicontinuous factors and the structure of \( E(X) \)

In this section, \( T \) is an abelian group. When we have a factor map between two dynamical systems, the acting group is the same. A dynamical system \((X, \sigma)\) is called **equicontinuous** if the family of homeomorphisms \( \{\sigma^t : t \in T\} \) is equicontinuous. If the action is transitive, then this is the case if and only if for any choice of \( x_0 \in X \) there is an abelian group structure on \( X \) (denoted additively) such that \( x_0 \) is the identity element and \( \sigma^t(x) = x + \sigma^t(x_0) - x_0 \). This group structure is topological.

Moreover, for a minimal equicontinuous system and w.r.t. the above group structure on \( X \), \( ev_{x_0} : E(X) \rightarrow X \) is an isomorphism of topological groups, where \( ev_{x_0} \) is evaluation at the point \( x_0 \in X \), \( ev_{x_0}(f) = f(x_0) \) [3, Chapter 3, Theorem 6].

An **equicontinuous** factor is a factor \( \pi : (X, \sigma) \rightarrow (Y, \delta) \) such that \((Y, \delta)\) is equicontinuous. As with any factor map, \( \pi \) induces a continuous semigroup morphism \( \pi_* : E(X) \rightarrow E(Y) \) via \( \pi_* (f)(y) = \pi(f(x)) \), where \( x \) is any preimage of \( y \) under \( \pi \). As \((Y, \delta)\) is equicontinuous, \( ev_{y_0} : E(Y) \rightarrow Y \) is a semigroup isomorphism, where \( y_0 \) is the identity element in \( Y \). We denote by \( \overline{\pi} : E(X) \rightarrow Y \) the composition \( ev_{y_0} \circ \pi_* \), which is also a continuous surjective semigroup morphism.

**Definition 2.10.** Let \( \pi : (X, \sigma) \rightarrow (Y, \delta) \) be an equicontinuous factor. Define \( E^{\text{fib}}(X) \) to be the subsemigroup of \( E(X) \) which consists of those elements which preserve the \( \pi \)-fibres \( \pi^{-1}(y) \), \( y \in Y \).

In other words, \( E^{\text{fib}}(X) \) is the kernel of the continuous semigroup morphism \( \overline{\pi} \) and therefore a closed subsemigroup. We summarize this situation with the exact sequence of right-topological semigroups

\[
E^{\text{fib}}(X) \hookrightarrow E(X) \xrightarrow{\overline{\pi}} Y
\]
in which the involved maps are continuous semigroup morphisms. While \( E(X) \) is only right topological, \( Y \) is topological. As we will see below, under certain circumstances, \( E^{\text{fib}}(X) \) is also a topological semigroup.

3. The fibre-preserving part \( E^{\text{fib}}(X) \)

In this section, we investigate the fibre-preserving part \( E^{\text{fib}}(X) \) of \( E(X) \) for dynamical systems which factor onto an equicontinuous system, \( \pi : X \rightarrow Y \). We call a point \( y \in Y \) regular (for \( \pi \)) if the proximal relation restricted to \( \pi^{-1}(y) \) is trivial. Otherwise we call the point singular (for \( \pi \)).

**Proposition 3.1.** Suppose that \( \pi : (X, \sigma) \rightarrow (Y, \delta) \) is an equicontinuous factor map whose fibres \( \pi^{-1}(y) \) are all finite. Then \( E^{\text{fib}}(X) \) is a compact topological semigroup.

**Proof.** \( E^{\text{fib}}(X) \) is a compact subsemigroup of \( F^{\text{fib}}(X) \), defined in Section 2.3. By assumption, all \( F(\pi^{-1}(y)) \) are (trivially) topological semigroups. Therefore the semigroup multiplication of \( \prod_{y \in Y} F(\pi^{-1}(y)) \) is jointly continuous. As \( E^{\text{fib}}(X) \) is a closed subsemigroup of \( F^{\text{fib}}(X) \), its product is also jointly continuous. \( \square \)

We can now apply Theorem 2.5 to conclude the following.

**Corollary 3.2.** Suppose that \( \pi : (X, \sigma) \rightarrow (Y, \delta) \) is an equicontinuous factor map whose fibres \( \pi^{-1}(y) \) are all finite. Then the kernel \( M^{\text{fib}}(X) \) of \( E^{\text{fib}}(X) \) is topologically isomorphic to its normalised Rees matrix form.
Recall by (2.5) that if $p$ is any minimal idempotent, then $pEp$ is a group. We fix any such minimal idempotent $e$, recalling that different minimal idempotents define isomorphic groups. As $\bar{\pi} : E \to Y$ is onto, and $\bar{\pi}(efe) = \bar{\pi}(f)$, the restriction $\tilde{\pi} : eEe \to Y$ is also onto. A lift under $\bar{\pi}$ is a right inverse $s : Y \to eEe$ to $\bar{\pi} : eEe \to Y$, i.e., it satisfies $\bar{\pi} \circ s = \text{Id}$. A lift always exists by the axiom of choice. We do not demand that it is continuous, nor, for the time being, that it preserves the group structure. But we can and do demand that it satisfies $s(\delta^t(y)) = \sigma^t s(y)$ for all $t \in T$, and also that $s(y)^{-1} = s(-y)$ for each $y \in Y$. We impose the latter condition now although we will not use it until Proposition 3.13.

Given a lift $s : Y \to eEe$, we define $\Phi^y_{y_1} : E^\text{fib} \to E^\text{fib}$ by

$$
\Phi^y_{y_1}(f) = s(y_2 - y_1)f s(y_2 - y_1)^{-1},
$$

(3.1)

where $s(z)^{-1}$ is the group inverse to $s(z)$. Although we do not include this in our notation, it must be kept in mind that $\Phi^y_{y_1}$ depends on the choice of lift. Since $s(\delta^t(y)) = \sigma^t s(y)$, we have $\Phi^y_{y_1}(s(y)) = \sigma^t \Phi^y_{y_1}(f)\sigma^{-t}$.

Note that $\Phi^y_{y_1}$ also defines a map from $E^\text{fib}_{y_1}$ to $E^\text{fib}_{y_2}$, namely, if $\varphi \in E^\text{fib}_{y_1}$ and $f$ is an element of $E^\text{fib}$ which restricts to $\varphi$ on $\pi^{-1}(y_1)$, that is $\varphi = \bar{\varphi}(y_1)$ in the notation above, then $\Phi^y_{y_1}(\varphi)$ is defined to be the restriction of $\Phi^y_{y_1}(f)$ to $\pi^{-1}(y_2)$. This does not depend on the choice of $f$, as $s(y_2 - y_1)^{-1}$ maps $\pi^{-1}(y_2)$ to $\pi^{-1}(y_1)$.

Lemma 3.3. Let $e \in E(X)$ be a minimal idempotent.

1. $eE^\text{fib}_y e$ is a group.

2. If $y$ is regular, then $eE^\text{fib}_y e = E^\text{fib}_y$.

3. For any $y_1, y_2$, the restriction $\Phi^y_{y_1} : eE^\text{fib}_y e \to eE^\text{fib}_{y_2} e$ is a group isomorphism.

Proof. $eE^\text{fib}_y e$ is entirely determined by the action of $eE^\text{fib}_y e$ on $e\pi^{-1}(y)$. It is hence the homomorphic image of a group.

Idempotents must act like the identity on a regular fibre, as can be seen as follows: the points $e(x)$ and $x$ are proximal. In a regular fibre this can only be the case if $e(x) = x$. Hence $eE^\text{fib}_y e = E^\text{fib}_y$ if $y$ is regular.

Let $s : Y \to eEe$ be a right inverse to $\bar{\pi} : eEe \to Y$; then $s(z)$ restricts to a map $e\pi^{-1}(y) \to e\pi^{-1}(y + z)$ whose inverse is the restriction of $s(z)^{-1}$, as $s(z)^{-1}s(z) = s(z)s(z)^{-1} = e$. Hence $\Phi^y_{y_1}$ is a conjugation with a bijection.

Definition 3.4. We call the group determined up to isomorphism by Lemma 3.3 the structure group of the factor system $(X, \sigma) \to (Y, \delta)$ and denote it by $G_\pi$.

Definition 3.5. We say that the system $(X, \sigma)$ is a unique singular orbit system if it admits an equicontinuous factor which has a single orbit of singular points.

We now specialize to the context of unique singular orbit systems and fix a singular point $y_0 \in Y$. Define $T \subset E^\text{fib}$ to be

$$
T = \{ f \in E^\text{fib} : f(x) = x \text{ for all } x \text{ in a regular fibre} \}.
$$

(3.2)
As idempotents can only project proximal pairs, and as regular fibres contain no proximal pairs, then idempotents must belong to \( T \). However, \( T \) may be larger. Given the minimal idempotent \( e \), \( e T e \) is a subsemigroup of \( e E^{\text{fib}} e \). We claim that it is even a normal subgroup. Indeed, if \( f \in e T e \), then its inverse in \( e E^{\text{fib}} e \) also acts trivially on regular fibres and so belongs to \( e T e \). Furthermore, an element \( g \in e E^{\text{fib}} e \) acts bijectively on regular fibres and hence \( g f g^{-1} e \) acts as \( g g^{-1} = 1 \) on them.

Let \( T_{y_0} \) be the restriction of \( T \) to \( \pi^{-1}(y_0) \); it is a subsemigroup of \( E^{\text{fib}}_{y_0} \). Then \( e T_{y_0} e \) is the restriction of \( e T e \) to \( e \pi^{-1}(y_0) \); it is a normal subgroup of \( e E^{\text{fib}}_{y_0} e \). We now use the maps \( \Phi_{y_0}^y \) from \((3.1)\) to transport the group \( e T_{y_0} e \) along \( Y \) and define the subsemigroup of \( \text{Cov} \)

\[
\text{Cov}_T := \{ \tilde{f} \in \text{Cov} : \tilde{f}(y_0) \in T_{y_0}, \text{ and } \tilde{f}(y) \in \Phi_{y_0}^y(e T_{y_0} e) \text{ for all } y \text{ regular} \}. \tag{3.3}
\]

Although the map \( \Phi_{y_0}^y \) depends on the choice of a lift \( s : Y \to e E e \) for \( \pi \), the space \( \text{Cov}_T \) does not. Indeed, if we take another lift to obtain a map \( \Phi_{y_0}^y(\tilde{f}(y_0)) \) will differ from \( \Phi_{y_0}^y(\tilde{f}(y_0)) \) by a conjugation with an element \( h \in e E^{\text{fib}}_{y_0} e \), which does not matter as \( e T_{y_0} e \) is a normal subgroup of \( e E^{\text{fib}}_{y_0} e \). By covariance, \( \text{Cov}_T \) does not depend on the choice of \( y_0 \) in the unique orbit of singular points. Finally, the dependence of \( \text{Cov}_T \) on the choice of minimal idempotent \( e \) can be controlled with the isomorphisms \((2.1)\) and \((2.2)\). If the singular fibre \( \pi^{-1}(y_0) \) is finite, then the isomorphisms are bicontinuous by Theorem 2.5 and Corollary 3.2.

**Theorem 3.6.** Let \( (X, \sigma) \) be a minimal unique singular orbit system. \( \text{Cov}_T \) is a subsemigroup of \( E^{\text{fib}} \).

**Proof.** Let \( g \in T \) and \( y \in Y \). Then \( f := \Phi_{y_0}^y(g) \) belongs to \( \text{Cov}_T \cap E^{\text{fib}} \). Indeed, \( \Phi_{y_0}^y(g) = \Phi_{y_0}^y(e ge) \in \Phi_{y_0}^y(e T_{y_0} e) \).

By definition \( g \) acts non-trivially only on the fibres of the \( T \)-orbit of \( y_0 \). Hence \( f := \Phi_{y_0}^y(g) \) acts non-trivially only on the fibres of the \( T \)-orbit of \( y \). As \( (\Phi_{y_0}^y)^{-1}(f(y)) \) is the restriction of \( e ge \) to \( e \pi^{-1}(y_0) \), we find that, given any regular point \( y \) and any \( g \in e T_{y_0} e \), \( \text{Cov}_T \cap E^{\text{fib}} \) contains the function \( f \) which satisfies \( (\Phi_{y_0}^y)^{-1}(f(y)) = g \) and \( f(y') = Id \) for any point \( y' \) in another orbit. By taking finite products of such functions we see that \( \text{Cov}_T \cap E^{\text{fib}} \) contains, for any choice of \( k \) points \( y_1, \ldots, y_k \) in distinct regular orbits and any choice of \( k + 1 \) elements \( g_i \in T_{y_0}, i = 0, \ldots, k \), a function \( f \) such that \( (\Phi_{y_0}^y)^{-1}(\tilde{f}(y_i)) = e g_i e, i \geq 1, \tilde{f}(y_0) = g_0 \), and \( f(y') = Id \) for a point \( y' \) in another orbit. By definition of the topology of pointwise convergence and since covariance is a closed relation, the set of these elements is dense in \( \text{Cov}_T \). Since \( E^{\text{fib}} \) is the kernel of a continuous map, it is closed; it hence contains \( \text{Cov}_T \).

**Corollary 3.7.** Let \( (X, \sigma) \) be a minimal unique singular orbit system. If \( E^{\text{fib}}_{y_0} = T_{y_0} \), then \( E^{\text{fib}} \) is topologically isomorphic to \( \text{Cov} \).

**Proof.** If \( E^{\text{fib}}_{y_0} = T_{y_0} \), then \( \Phi_{y_0}^y(e T_{y_0} e) = E^{\text{fib}}_y \), for regular \( y \), so that the condition \( \tilde{f}(y) \in \Phi_{y_0}^y(e T_{y_0} e) \) is trivially satisfied as is \( \tilde{f}(y_0) \in T_{y_0} \). Hence \( \text{Cov}_T = \text{Cov} \). Thus by Theorem
3.6 we have Cov \subseteq E^{\text{fib}}. On the other hand, we saw that \(E^{\text{fib}}\) is a subsemigroup of Cov and that the inclusion is continuous. Since Cov is compact, this gives the result.

We end this section by establishing a criterion which implies the condition of the last corollary, namely that \(E^{\text{fib}}_{y_0} = \mathcal{T}_{y_0}\).

**Definition 3.8.** Let \(\pi : (X, \sigma) \to (Y, \delta)\) be an equicontinuous factor. The minimal rank \(r_\pi\) of the factor \(\pi\) is the smallest possible cardinality \(|\pi^{-1}(y)|\) of a fibre, \(y \in Y\). The coincidence rank \(cr_\pi(y)\) of the fibre \(y \in Y\) is the largest possible cardinality a subset of \(\pi^{-1}(y)\) can have, which contains only pairwise non-proximal elements.

If the system \((X, \sigma)\) is minimal, then the coincidence rank of an equicontinuous factor can be shown to be independent of \(y\) and so \(cr_\pi = cr_\pi(y)\) is the coincidence rank of the factor \(\pi : (X, \sigma) \to (Y, \delta)\). If the factor is not specified, then the coincidence rank is meant to be the coincidence rank of the maximal equicontinuous factor. See [2] for details and a context. Not every system contains regular fibres. It can be shown that, for minimal systems with finite coincidence rank for the maximal equicontinuous factor, the maximal equicontinuous factor contains a regular fibre if and only if the system is point distal, i.e., contains a point \(x\) that is proximal only to itself [2], and if that is the case, any other equicontinuous factor must also contain regular fibres. (Since this is a side remark, we do not include a proof.)

**Lemma 3.9.** If the minimal rank \(r_\pi\) of the equicontinuous factor \(Y\) of a minimal system is finite and the factor contains some regular fibre, then \(y \in Y\) is regular if and only if \(|\pi^{-1}(y)| = r_\pi\).

**Proof.** Let \(y_0\) be a regular point. Then \(cr_\pi = |\pi^{-1}(y_0)|\). It follows that \(cr_\pi \geq r_\pi\). On the other hand, since \(r_\pi\) is finite, there exists a point \(y_1\) for which \(r_\pi = |\pi^{-1}(y_1)|\). Clearly, \(cr_\pi(y_1) \leq |\pi^{-1}(y_1)|\). Hence \(cr_\pi = r_\pi\). Thus all points of a fibre with \(r_\pi\) points must be pairwise non-proximal, and moreover, a fibre cannot contain more than \(r_\pi\) pairwise non-proximal points.

**Lemma 3.10.** Let \(\pi : (X, \sigma) \to (Y, \delta)\) be an equicontinuous factor with finite minimal rank. Let \(f \in E^{\text{fib}}\) be an element which acts on the singular fibres as an idempotent. Then for some \(N\), \(f^N = f\) on the singular fibres and \(f^N = \text{Id}\) on the regular fibres.

**Proof.** Since regular fibres contain only distal points, and only finitely many, any element of \(f \in E^{\text{fib}}\) must act on a regular fibre as a bijection. Since regular fibres have \(r_\pi\) elements, then if \(N = r_\pi\), \(f^N\) acts like the identity on a regular fibre. If \(f\) acts like an idempotent on the singular fibre, then \(f^N\) acts like \(f\) on the singular fibres.

We denote by \(Y/T\) the space of \(T\)-orbits of \(Y\) and its elements by \([y]\).

**Corollary 3.11.** Consider a unique singular orbit system with finite minimal rank. Let \(y_0 \in Y\) be singular. The restriction \(\mathcal{T}_{y_0}\) of \(\mathcal{T}\) to \(\pi^{-1}(y_0)\) contains all idempotents of \(E^{\text{fib}}_{y_0}\).
In particular, if $E_{y_0}^{\text{fib}}$ is generated by its idempotents, then $E_{y_0}^{\text{fib}} = \mathcal{T}_{y_0}$ and consequently,

$$E_{y_0}^{\text{fib}} = \text{Cov} \cong E_{y_0}^{\text{fib}} \times \prod_{[y] \in Y/T \setminus y \neq y_0} G_\pi.$$ 

This is a topological isomorphism if we equip the right-hand side with the product topology.

**Proof.** Any idempotent of $E_{y_0}^{\text{fib}}$ is the restriction of an element $f \in E^{\text{fib}}$ which, by Lemma 3.10, may be assumed to act trivially on all regular fibres. Hence any idempotent of $E_{y_0}^{\text{fib}}$ is the restriction of an element $f \in \mathcal{T}$. Under the assumption of finite minimal rank, the structure group $G_\pi$ must be finite and thus topologically isomorphic to $E_y^{\text{fib}}$ for regular $y$. Covariance allows us to factor out the action of $\mathcal{T}$ and thus describe Cov as a direct product over the space of orbits $Y/T$.

### 3.1. Recovering $E(X)$ from $E^{\text{fib}}(X)$ and $Y$

Although we now have a pretty good description of $E^{\text{fib}}(X)$ and $Y$ for unique singular orbit systems with finite minimal rank, it is not obvious how this describes $E(X)$. As our interest lies in minimal systems which have a singular fibre, their Ellis semigroup must contain two non-commuting idempotents. This implies that $E(X)$ cannot be left topological\(^2\), even when $E^{\text{fib}}(X)$ and $Y$ are topological. This is a sign that we cannot expect a semidirect product construction, paralleling that of groups, which describes $E(X)$ with its topology through $E^{\text{fib}}(X)$ and $Y$. However, on the purely algebraic side, we will see that Proposition 2.6 turns out to be useful in this regard.

**Notation 3.12.** We let $\mathcal{M}(X)$ denote the kernel of $E(X)$ and let $\mathcal{M}^{\text{fib}}(X)$ denote the kernel of $E^{\text{fib}}(X)$. Recall that these kernels are completely simple. Picking a minimal idempotent $e$, we let $\mathcal{G} = eE(X)e$ and $\mathcal{G}^{\text{fib}} = eE^{\text{fib}}(X)e$ denote the Rees structure groups of $\mathcal{M}(X)$ and $\mathcal{M}^{\text{fib}}(X)$, respectively.

As $Y = \tilde{\pi}(E(X)) = \tilde{\pi}(eE(X)) \subset \tilde{\pi}(\mathcal{M}(X))$, (2.7) gives rise to the exact sequence

$$E^{\text{fib}}(X) \cap \mathcal{M}(X) \hookrightarrow \mathcal{M}(X) \twoheadrightarrow Y.$$ 

$E^{\text{fib}}(X) \cap \mathcal{M}(X)$ contains all idempotents of $\mathcal{M}(X)$. Moreover, it is simple, as can be seen as follows: as $\mathcal{M}(X)$ is completely simple, given $x, y \in E^{\text{fib}}(X) \cap \mathcal{M}(X)$, there is an idempotent $z \in \mathcal{M}(X)$ such that $x, z$ belong to the same minimal left, while $z, y$ belong to the same minimal right ideal of $\mathcal{M}(X)$. Since $z$ is an idempotent, we have $z \in E^{\text{fib}}(X)$. Since $x, z \in E^{\text{fib}}(X) \cap \mathcal{M}(X)$ belong to the same minimal left ideal of $\mathcal{M}(X)$, then there is $a \in \mathcal{M}(X)$ such that $x = az$. It follows that $\tilde{\pi}(a) = 0$; thus $a$ ∈ $E^{\text{fib}}(X) \cap \mathcal{M}(X)$ contains all idempotents of $\mathcal{M}(X)$.

\(^2\)Since $\mathcal{T}$ is abelian, if left multiplication is continuous, then $\lim_{\sigma} \sigma^{t_\mu} \lim_{\mu} \sigma^{s_\mu} = \lim_{\mu} \lim_{\sigma} \sigma^{t_\mu + s_\mu} = \lim_{\mu} \sigma^{s_\mu} \lim_{\sigma} \sigma^{t_\mu}$; hence all elements of $E(X)$ commute.
$E^{\text{fib}}(X) \cap \mathcal{M}(X)$. Similarly, since $z, y \in E^{\text{fib}}(X) \cap \mathcal{M}(X)$ belong to the same minimal right ideal of $\mathcal{M}(X)$, then there is $b \in E^{\text{fib}}(X) \cap \mathcal{M}(X)$ such that $z = yb$. Hence $x = aby$ for $a, b \in E^{\text{fib}}(X) \cap \mathcal{M}(X)$. This proves that $E^{\text{fib}}(X) \cap \mathcal{M}(X)$ is simple and therefore equal to the kernel $\mathcal{M}^{\text{fib}}(X)$ of $E^{\text{fib}}(X)$.

A further restriction of (2.7) to $e\mathcal{M}(X)e$ leads to the exact sequence of groups

$$G^{\text{fib}} \to G \xrightarrow{\pi} Y.$$  

We show now that for systems which satisfy the conclusion of Corollary 3.7 the above sequence has a split section, so that the structure group $G$ is the semidirect product of $G^{\text{fib}}$ with the group $Y$.

**Proposition 3.13.** Let $(X, \sigma)$ be a minimal system with an equicontinuous factor $\pi : (X, \sigma) \to (Y, \delta)$ such that $E^{\text{fib}} = \text{Cov}$. Let $e$ be a minimal idempotent of $E$ and $s : Y \to eEe$ be a lift of $\pi$ which satisfies $s(\delta^t(y)) = \sigma^t s(y)$ and $s(-y) = s(y)^{-1}$. Define, for $y \in Y$, the map $\hat{s}(y) : eX \to eX$ by

$$\hat{s}(y)(x) = s(\pi(x) + y)s(\pi(x))^{-1}(x).$$

Then $\hat{s} : Y \to eEe$ is a right inverse to $\pi$ which satisfies $\hat{s}(\delta^t(y)) = \sigma^t \hat{s}(y)$ and is a group homomorphism.

**Proof.** Let $y \in Y$. By definition

$$\hat{s}(y)(x) = s(y)g(\pi(x))(x),$$

where $g(z) = s(y)^{-1}s(z + y)s(z)^{-1}$. We see that $g(z)(x) \in e\pi^{-1}(z)$ for all $x \in e\pi^{-1}(z)$, hence $g(z) : e\pi^{-1}(z) \to e\pi^{-1}(z)$ is an element of $eE^{\text{fib}}_z e$. Using $s(\delta^t(y)) = \sigma^t s(y)$, we obtain $g(\delta^t(\pi(x)))(\sigma^t x) = \sigma^t g(\pi(x))(x)$. Thus $Y \ni z \mapsto g(z) \in eE^{\text{fib}}_z e$ is covariant along the orbit of $y$ and hence an element of $e\text{Cove}$. By assumption $e\text{Cove} = eE^{\text{fib}}_z e$. Thus $\hat{s}(y) = \hat{s}(y)g$ is an element of $eEe$.

We show that $\hat{s}(y)$ is a right inverse to $\pi$. Let $x \in \pi^{-1}(0)$. We have

$$\pi \hat{s}(y) = \pi * (\hat{s}(y))(0) = \pi(\hat{s}(y)(x)) = \pi(s(y)(x)) = y + \pi(x) = y,$$

where we have used $s(0)^{-1} = e$ in the third equality. The identity $\hat{s}(\delta^t(y)) = \sigma^t \hat{s}(y)$ follows readily. It remains to show that $\hat{s}$ is multiplicative:

$$\hat{s}(y_1 + y_2)(x) = s(\pi(x) + y_1 + y_2)s(\pi(x))^{-1}(x)$$

$$= s(\pi(x) + y_1 + y_2)s(\pi(x) + y_2)^{-1}s(\pi(x) + y_2)s(\pi(x))^{-1}(x)$$

$$= \hat{s}(y_1) \hat{s}(y_2)(x).$$

**Corollary 3.14.** Let $(X, T, \sigma)$ be a minimal system with an equicontinuous factor $\pi : (X, \sigma) \to (Y, \delta)$ such that $E^{\text{fib}} = \text{Cov}$. Then the structure group $G^{\text{fib}}$ of $\mathcal{M}^{\text{fib}}(X)$ is isomorphic to $G_{\pi}^{Y/T}$. Moreover, the structure group of $\mathcal{M}(X)$ is $G = G^{\text{fib}} \rtimes Y$. Furthermore, if $M[G^{\text{fib}}; I, \Lambda; A]$ is the normalised Rees matrix form for $\mathcal{M}^{\text{fib}}(X)$ w.r.t. $e$, then $\mathcal{M}(X)$ is algebraically isomorphic to $M[G^{\text{fib}} \rtimes Y; I, \Lambda; A]$. 
Proof. Apply Proposition 2.6, Corollary 3.2, and Proposition 3.13.

For unique singular orbit systems with finite minimal rank and for which $E^\text{fib}_{y_0}(X)$ is generated by its idempotents, we have now reduced the calculation of the kernel of their Ellis semigroup to the calculation of the kernel of $E^\text{fib}_{y_0}(X)$ which we denote $\mathcal{M}^\text{fib}_{y_0}(X)$. Indeed, if $M[G; I, \Lambda; A]$ is the normalised matrix form of $\mathcal{M}^\text{fib}_{y_0}(X)$ w.r.t. $e$, then $G = G_\pi$ which we may identify with the subgroup $G_\pi \times \prod_{[y_0] \neq [y] \in Y/T} \{1\}$ of $G^Y/T$. It follows that

$$\mathcal{M}^\text{fib}(X) \cong M[G_\pi; I, \Lambda; A] \times \prod_{[y_0] \neq [y] \in Y/T} G_\pi \cong M[G^Y/T; I, \Lambda; A], \quad (3.4)$$

where the second topological isomorphism is given by the map

$$(i, g, \lambda, f) \mapsto (i, (g, f), \lambda).$$

We will see in the next section how to compute $G_\pi$, $I$, $\Lambda$, and $A$ for systems arising from bijective substitutions.

4. Bijective substitutions and their Ellis semigroup

In this section, we discuss the Ellis semigroup of a family of minimal $\mathbb{Z}$-actions which are both unique singular orbit systems, and also systems for which forward/backward proximality is non-trivial and agrees with forward/backward asymptoticity. This is the family of bijective constant length substitution shifts. For these systems, Corollary 2.9 tells us that $E(X)$ is the disjoint union of its kernel $\mathcal{M}(X)$ with the acting group $\mathbb{Z}$, so that a description of $\mathcal{M}(X)$ suffices to completely describe the Ellis semigroup. Next, for most of these systems, Corollary 3.14 will apply, so that we are on the way to describing $\mathcal{M}(X)$ once we know its restriction to a singular fibre which we call below the structural semigroup. This is the content of Theorem 4.6. We consolidate to get a global statement in Theorem 4.12. Finally, we identify the substitution shifts to which we cannot apply Corollary 3.14, and we replace it with Theorem 4.22.

4.1. Generalities

We briefly summarise the notation and results concerning substitutions that we will need; for an extensive background see [5] or [13].

A substitution is a map from a finite set $\mathcal{A}$, the alphabet, to the set of nonempty finite words (finite sequences) on $\mathcal{A}$. We extend $\theta$ to a map on finite words by concatenation:

$$\theta(a_1 \cdots a_k) = \theta(a_1) \cdots \theta(a_k), \quad (4.1)$$

and to bi-infinite sequences $\cdots u_{-2}u_{-1}u_0u_1 \cdots$ as

$$\theta(\cdots u_{-2}u_{-1}u_0u_1 \cdots) := \cdots \theta(u_{-2})\theta(u_{-1})\theta(u_0)\theta(u_1) \cdots .$$

Here the $\cdot$ indicates the position between the negative indices and the nonnegative indices.
We say that $\theta$ is primitive if there is some $k \in \mathbb{N}$ such that, for any $a, a' \in \mathcal{A}$, the word $\theta^k(a)$ contains at least one occurrence of $a'$. We say that a finite word is allowed for $\theta$ if it appears somewhere in $\theta^k(a)$ for some $a \in \mathcal{A}$ and some $k \in \mathbb{N}$.

The substitution shift $(X_\theta, \sigma)$ is the dynamical system where the space $X_\theta$ consists of all bi-infinite sequences all of whose subwords are allowed for $\theta$. If $\theta$ is primitive, $X_\theta = X_{\theta^n}$ for each $n \in \mathbb{N}$. We equip $X_\theta$ with the subspace topology of the product topology on $\mathcal{A}^\mathbb{Z}$, making the left shift map $\sigma$ a continuous $\mathbb{Z}$-action. Primitivity of $\theta$ implies that $(X_\theta, \sigma)$ is minimal.

We say that a primitive substitution is aperiodic if $X_\theta$ does not contain any $\sigma$-periodic sequences. This is the case if and only if $X_\theta$ is an infinite space. The substitution $\theta$ has (constant) length $\ell$ if for each $a \in \mathcal{A}$, $\theta(a)$ is a word of length $\ell$. In this case, one can describe the substitution with $\ell$ maps $\theta_i : \mathcal{A} \to \mathcal{A}$, $0 \leq i \leq \ell - 1$, such that

$$\theta(a) = \theta_0(a) \cdots \theta_{\ell - 1}(a)$$

for all $a \in \mathcal{A}$. A substitution $\theta$ is bijective if it has constant length and each of the maps $\theta_i$ is a bijection. If $\theta$ is bijective, then $X_\theta$ is the disjoint union of finitely many primitive bijective substitution shifts, and consequently its Ellis semigroup is also the disjoint union of finitely many Ellis semigroups of primitive substitution shifts. Henceforth we assume that $\theta$ is primitive but this comment means that all our results have analogous statements for non-primitive bijective substitutions.

We say that the bijective $\theta$ is simplified if

1. every $\theta$-periodic point is a fixed point of $\theta$, so that in particular $\theta_0 = \theta_{\ell - 1} = 1$, and

2. each word $\theta(a)$ contains all letters from $\mathcal{A}$.

Given any bijective substitution $\theta$, both properties will be satisfied by a large enough power $\theta^n$ of $\theta$. Indeed, if $M$ is the lowest common multiple of the least periods of the periodic points, then each periodic point is a fixed point under $\theta^M$. Since for any $n \in \mathbb{N}$, $X_\theta = X_{\theta^n}$, there will be no loss in generality in assuming that $\theta$ is simplified and this is henceforth a standing assumption.

### 4.2. An equicontinuous factor with a unique orbit of singular fibres

Let $\theta$ be an aperiodic primitive substitution of length $\ell$. Define $B^{(n)} := \theta^n(X_\theta)$, which is a clopen subset of $X_\theta$. Then $\sigma^i(B^{(n)}) = \sigma^j(B^{(n)})$ if $i - j \equiv 0 \mod \ell^n$ whereas otherwise $\sigma^i(B^{(n)}) \cap \sigma^j(B^{(n)}) = \emptyset$ [11, Lemma II.7]. In other words,

$$\mathcal{P}_n = \{\sigma^k(B^{(n)}) : 0 \leq k \leq \ell^n - 1\}$$

is a $\sigma^{-\ell^n}$-cyclic partition of $X_\theta$ of size $\ell^n$. For $n \geq 1$, define $\pi_n : X_\theta \to \mathbb{Z}/\ell^n \mathbb{Z}$ by

$$\pi_n(x) = i \quad \text{if} \quad x \in \sigma^i(B^{(n)}) .$$

The map $\pi_n$ can be described as follows. Using the partition $\mathcal{P}_1$, any bi-infinite sequence $x = (x_i)_{i \in \mathbb{Z}} \in X_\theta$ can be uniquely decomposed into blocks of length $\ell$ such that
(i) the $i$th block is a substitution word $\theta(a_i)$, for some $a_i \in \mathcal{A}$. Here we say that the 0th block is the one which contains $x_0$, and

(ii) the sequence $(a_i)_{i \in \mathbb{Z}}$ is an element of $X_\theta$.

Now set $\pi_1(x) := i$ if the 0th block starts at index $-i$ (if we shift that block $i$ units to the right then its first letter has index 0). This procedure can be performed with $\mathcal{P}_n$ and $\theta^n$ yielding an analogous definition for $\pi_n(x)$. In particular, the $\pi_n$ are pattern equivariant (or local) and hence continuous. Note that if $\pi_n(x) = i$, then $\pi_{n+1}(x) \equiv i \mod \ell^n$. Therefore the collection of these maps $\pi_n$ defines a continuous map

$$\pi : X_\theta \to Y := \lim_{\rightarrow} \mathbb{Z}/\ell^n\mathbb{Z} \quad \text{(4.2)}$$

onto the inverse limit $\lim_{\rightarrow} \mathbb{Z}/\ell^n\mathbb{Z}$ defined by the canonical projections $\mathbb{Z}/\ell^{n+1}\mathbb{Z} \twoheadrightarrow \mathbb{Z}/\ell^n\mathbb{Z}$. The inverse limit space can be identified with the space of left-sided sequences $(y_i)_{i < 0} = \cdots y_{-2} y_{-1}, 0 \leq y_i < \ell$, and then $\pi(x) = (y_i)_{i < 0}$ is such that for each positive integer $n$, $\pi_n(x) = \sum_{i=-n}^{-1} \ell^{-i-1} y_i$. It then follows that $\pi \circ \sigma = (+1) \circ \pi$, where $(+1)$ is addition of 1 = $\cdots$ 001 (only the last digit is not 0) with carry over. Its additive inverse is addition of $-1 = \cdots \ell - 1 \ell - 1 \ell - 1$ in other words, $(X_\theta, \sigma)$ factors onto the odometer with $\ell$ digits (adding machine). This is the equicontinuous factor map with which we work. As the space is the space of $\ell$-adic integers, we will denote it using the notation $\mathbb{Z}_\ell$.

**Proposition 4.1.** Let $\theta$ be a primitive aperiodic bijective (and simplified) substitution of length $\ell$ and let $\pi : X_\theta \to \mathbb{Z}_\ell$ be defined by (4.2). The fibre $\pi^{-1}(0)$ contains exactly the $\theta$-fixed points. These are in one-to-one correspondence with the allowed two-letter words.

**Proof.** It is quickly seen that $\pi \circ \theta = (\times \ell) \circ \pi$, where $(\times \ell)$ is multiplication by $\ell$ in $\mathbb{Z}_\ell$ and corresponds to left shift with adjoining a 0: $(\times \ell)(\cdots y_{-2} y_{-1}) = \cdots y_{-2} y_{-1} 0$. Hence any $\theta$-fixed point is mapped by $\pi$ to a $(\times \ell)$-fixed point in $\mathbb{Z}_\ell$, and the only such one is 0. Thus all $\theta$-fixed points belong to $\pi^{-1}(0)$. It also follows that $\theta$ must preserve $\pi^{-1}(0)$.

Since the maps $\theta_i$ are bijections of $\mathcal{A}$, $\theta$ is injective on $X_\theta$. Hence it is injective on $\pi^{-1}(0)$. We claim that $\pi^{-1}(0)$ must be finite. To prove the claim, let $x, x' \in X_\theta$. If $x \neq x'$, there exists $n \in \mathbb{N}$ such that $x_{[-\ell^n,\ell^n-1]} \neq x'_{[-\ell^n,\ell^n-1]}$ (here $x_{[n,m]}$ is the word $x_n x_{n+1} \cdots x_m$). It follows that $\theta^{-n}(x)_{[-1,0]} \neq \theta^{-n}(x')_{[-1,0]}$. Since there are only finitely many words of length two, $\pi^{-1}(0)$ must be finite. It follows that the restriction of $\theta$ to $\pi^{-1}(0)$ is bijective and thus $\pi^{-1}(0)$ must be a union of periodic orbits under $\theta$.

As $\theta$ is bijective and simplified, we have $\theta(x)_{[-1,0]} = x_{[-1,0]}$ for any $x \in X_\theta$. It follows that $\theta$-periodic points are $\theta$-fixed points and that they are in one-to-one correspondence with the allowed two-letter words.

**Proposition 4.2.** Let $\theta$ be a primitive aperiodic bijective substitution of length $\ell$ and let $\pi : X_\theta \to \mathbb{Z}_\ell$ be defined by (4.2). Then the orbit of $\pi^{-1}(0)$ is the only singular fibre orbit. The minimal rank is $r_\pi = s$, where $s$ is the size of the alphabet.

**Proof.** Suppose that $y = \cdots y_{-2} y_{-1}$ does not belong to the $\mathbb{Z}$-orbit of 0. This is the case precisely if for infinitely many $n$, $y_{-n} \neq 0$ and, for infinitely many $n$, $y_{-n} \neq \ell - 1$. 

Now if we take \( x \in \pi^{-1}(y) \) and decompose it into substitution words \( \theta^n(a) \) of level \( n \) (as described above), then the substitution word \( \theta^n(a_0) \) which covers index 0 must be \( \theta^n(a_0) = x_{[k_n, k_n + \ell^n - 1]} \), where \( k_n = -\sum_{i=-n}^{-1} \ell^{-i-1} y_i \). Since \( y_{-n} \neq 0 \) for infinitely many \( n \) we have \( k_n \xrightarrow[n \to \infty]{} -\infty \), and since \( y_{-n} \neq 1 \) for infinitely many \( n \) we have \( k_n + \ell^n - 1 \xrightarrow[n \to \infty]{} +\infty \). Furthermore, by bijectivity of \( \theta \), \( a_0 \) is uniquely determined by \( x_0 \). It follows that \( x \) is uniquely determined by \( y \) and \( x_0 \). Since there are exactly \( s \) choices for \( x_0 \), we see that \( \pi^{-1}(y) \) contains \( s \) elements.

We now show that \( \pi^{-1}(y) \) is a regular fibre if \( y \) does not belong to the orbit of \( \mathbb{Z} \). Suppose that \( x, x' \) were proximal. Then there exists \( n \in \mathbb{Z} \) such that \( x_n = x'_n \). In other words, \( \sigma^n(x)_0 = \sigma^n(x')_0 \). Also \( y + n \) does not belong to the \( \mathbb{Z} \)-orbit of 0 and since \( \sigma^n(x), \sigma^n(x') \in \pi^{-1}(y + n) \) we conclude from the above that \( x = x' \). Hence all points of \( \pi^{-1}(y) \) are pairwise non-proximal.

We have seen above that \( \pi^{-1}(0) \) has \( s^{(2)} \) elements, where \( s^{(2)} \) is the number of allowed two-letter words. Given that \( \theta \) is aperiodic, we must have \( s^{(2)} > s \). Thus \( \pi^{-1}(0) \) cannot be a regular fibre.

Since \( \theta \) is simplified, its fixed points are precisely those of the form \( \theta^\infty(a) \cdot \theta^\infty(b) \), where \( ab \) is an allowed word for \( \theta \). Such a fixed point is uniquely determined by \( ab \). We will use the notation \( a \cdot b \) to denote it.

**Corollary 4.3.** Let \( \theta \) be a primitive bijective aperiodic substitution of constant length. If two points \( x, x' \in X_\theta \) are forward (or backward) proximal, then they are forward (or backward) asymptotic. Furthermore, forward and backward proximal elements are non-trivial.

In particular, the Ellis semigroup \( E(X_\theta) \) is completely regular and is the disjoint union of its kernel \( \mathcal{M}(X_\theta) \) with \( \mathbb{Z} \).

**Proof.** Suppose that \( x, x' \in X_\theta \) are forward proximal. Then they are proximal and so by Propositions 4.2 and 4.1 there is \( n \in \mathbb{Z} \) such that \( \sigma^n(x) \) and \( \sigma^n(x') \) are fixed points of the (simplified) substitution. Since they are forward proximal and \( \sigma \) is left shift, this means that there are allowed two-letter words \( ba, b'a \) such that \( \sigma^n(x) = b \cdot a \) and \( \sigma^n(x') = b' \cdot a \). In particular, the two sequences agree to the right and hence are forward asymptotic. If forward proximality were trivial, then every two-letter word would be determined by its right letter. This cannot be the case as the substitution is aperiodic. Hence forward proximality is non-trivial. For the backward motion we argue in a similar way. The result now follows from Corollary 2.9.

### 4.3. The kernel \( \mathcal{M}^\text{fib}_0(X_\theta) \)

The restriction \( E_0^\text{fib}(X_\theta) \) of \( E^\text{fib}(X_\theta) \) to the singular fibre \( \pi^{-1}(0) \) of the factor map \( \pi : X_\theta \to \mathbb{Z}_+ \) contains besides the identity map only its kernel \( \mathcal{M}^\text{fib}_0(X_\theta) \). This kernel is a finite semigroup which we now compute. We also call it the *structural semigroup* of \( \theta \). It completely determines \( E^\text{fib}(X_\theta) \).

Recall that since \( \theta \) has length \( \ell \) there are maps \( \theta_i : \mathcal{A} \to \mathcal{A} \) such that

\[
\theta(a) = \theta_0(a) \cdots \theta_{\ell-1}(a) \quad \text{for all } a \in \mathcal{A}.
\]
\( \theta \) is thus uniquely determined by what we call its \textit{expansion}, namely its representation as a concatenation of \( \ell \) maps, which we write as

\[
\theta = \theta_0|\theta_1|\cdots|\theta_{\ell-1}.
\]

It follows from (4.1) that the composition of two substitutions \( \theta, \theta' \) of lengths \( \ell \) and \( \ell' \) over the same alphabet (which we simply denote by \( \theta \theta' \)) has then an expansion into \( \ell \ell' \) maps

\[
\theta \theta' = \theta_0\theta'_0|\cdots|\theta_{\ell-1}\theta'_0|\theta_0\theta'_1|\cdots|\theta_{\ell-1}\theta'_{\ell'-1},
\]

where the product \( \theta_i\theta'_j \) is that of permutations, that is, composition of bijections. In particular, the expansion of \( \theta^2 \) is given by

\[
(\theta^2)_0|\cdots|(\theta^2)_{\ell^2-1} = \theta_0\theta_0|\cdots|\theta_{\ell-1}\theta_0|\theta_0\theta_1|\cdots|\theta_{\ell-1}\theta_{\ell-1}
\]  \hspace{1cm} (4.3)

and iteratively we find, for any given \( n \) the \( \ell^n \) bijections \( (\theta^n)_i \) corresponding to the expansion of \( \theta^n \).

\textbf{Definition 4.4.} Given a bijective substitution \( \theta \), we define the \textit{structure group} \( G_\theta \) of \( \theta \) to be the group generated by all the bijections \( (\theta^n)_i, n \in \mathbb{N}, i = 0, \ldots, \ell^n - 1 \), and its \textit{R-set} by

\[
I_\theta := \{(\theta^n)_i(\theta^n)_{i-1}^{-1} \in G_\theta : n \in \mathbb{N}, i = 1, \ldots, \ell^n - 1\}.
\]

Note that \( I_\theta \) is the collection of bijections we need to apply (from the left) to go from some element \( (\theta^n)_{i-1} \) in the expansion of some power of the substitution to its successor \( (\theta^n)_i \). The name \( R \)-set is motivated by the fact that \( I_\theta \) will label the right ideals of \( \mathcal{M}_0^{\text{fib}}(X_\theta) \).

\textbf{Lemma 4.5.} If \( \theta \) is simplified, then \( G_\theta \) is generated by \( I_\theta \) and

\[
I_\theta = \{\theta_i\theta_{i-1}^{-1} \in G_\theta : i = 1, \ldots, \ell - 1\}.
\]

\textit{Proof.} The first statement follows recursively as \( \theta_i = \theta_i\theta_{i-1}^{-1}\theta_{i-1} \) and \( \theta_0 = 1 \). We prove the second statement for \( n = 2 \) as the general statement then follows by induction. Let \((\theta^2)_{i-1}(\theta^2)_i\) be two consecutive bijections in the expansion of \( \theta^2 \). We consider two cases: in the first case, \((\theta^2)_{i-1}(\theta^2)_i\) appears as two consecutive columns in a single substitution word; in the second case, it lies on the boundary, across two substitution words.

In the first case, \((\theta^2)_{i-1}(\theta^2)_i = \theta_{j-1}\theta_k|\theta_j\theta_k\) for some \( j \leq \ell - 1 \) and some \( 0 \leq k \leq \ell - 1 \), as in (4.3). But then

\[
(\theta^2)_i(\theta^2)_{i-1}^{-1} = \theta_j\theta_k(\theta_j^{-1}\theta_k)^{-1} = \theta_j(\theta_{j-1})^{-1},
\]

and we are done as this last expression belongs to \( I \).

In the second case, \((\theta^2)_{i-1}(\theta^2)_i = \theta_{\ell-1}\theta_0\theta_{k+1} \) for some \( k < \ell - 1 \). Since \( \theta \) is simplified, \( \theta_0 = \theta_{\ell-1} = 1 \), and here also we are done. \( \blacksquare \)

In this section, we will prove Theorem 4.6; in its statement the semigroup has a sandwich matrix as defined in (2.3).
**Theorem 4.6.** Let θ be a primitive aperiodic bijective substitution. The structural semigroup \( \mathcal{M}^{fib}_0(X_\theta) \) of θ is isomorphic to the matrix semigroup \( M[G_\theta, I_\theta, \{\pm\}; A] \), where \( G_\theta \) is the structure group and \( I_\theta \) is the R-set of θ.

We will first give a description of \( \mathcal{M}^{fib}_0(X_\theta) \) as a subsemigroup of \( F(\pi^{-1}(0)) \), the set of functions from \( \pi^{-1}(0) \) to itself, and then compute its Rees matrix form.

We recall that \( \pi^{-1}(0) \) is the set of fixed points of \( \theta \) which we denote by \( a \cdot b \), where \( ab \) is an allowed two-letter word of \( \mathcal{A} \). To describe the action of \( E^{fib}(X_\theta) \) on such a fixed point \( a \cdot b \), we consider the set \( G(2) \) of all possible pairs of consecutive permutations \( (\theta^n)_{i-1}, (\theta^n)_i \), occurring in \( \theta^n, n \in \mathbb{N}, i = 1, \ldots, \ell^n - 1 \). We write them with a dot \( (\theta^n)_{i-1} \cdot (\theta^n)_i \) or abstractly \( L \cdot R \). We note that the R-set is related to \( G(2) \), namely

\[
I_\theta = \{ RL^{-1} : L \cdot R \in G(2) \}.
\]

Notice also that \( G(2) \) is the same for any power of the substitution.

**Lemma 4.7.** \( G(2) \) is invariant under the right diagonal \( G_\theta \)-action

\[
(L \cdot R)g = (Lg \cdot Rg).
\]

**Proof.** Suppose that \( L \cdot R \in G(2) \), then for some \( k \in \mathbb{N} \) and \( 0 < i < \ell^k \) it appears as \( L \cdot R = (\theta^k)_{i-1} \cdot (\theta^k)_i \). Let \( g \in G_\theta \), so that it appears as \( g = (\theta^n)_j \) for some \( n \in \mathbb{N} \) and some \( 0 \leq j \leq \ell^n - 1 \). Then, using the expansion of \( \theta^n \) obtained in (4.3), we find that \( Lg \cdot Rg \) appears as two consecutive columns in the expansion of \( \theta^{n+k} \) and hence belongs to \( G(2) \) for each \( g \in G_\theta \). \( \blacksquare \)

As we assume that \( \theta \) is simplified, we have \( (\theta^k)_0 = (\theta^k)_{\ell^k-1} = 1 \) for each \( k \geq 1 \). Then

\[
\theta^k (L|R) = (\theta^k)_0 L \cdots (\theta^k)_{\ell^k-2} L | L \cdots (\theta^k)_{\ell^k-1} R,
\]

where we have used that \( (\theta^k)_{\ell^k-1} L = L \) and \( (\theta^k)_0 R = R \). Hence if \( L \cdot R = (\theta^n)_{i-1} \cdot (\theta^n)_i \) then the expansion of \( \theta^k \theta^n \) contains \( \theta^k (\theta^n)_{i-1} (\theta^k (\theta^n)_i \) at positions \([\ell^k (i-2), \ell^k i - 1]\).

**Proposition 4.8.** Let \( L \cdot R \in G(2) \). Then \( E^{fib} \) contains an element \( f_{[L \cdot R; \ast]} \) which acts on the singular fibre \( \pi^{-1}(0) \) as

\[
f_{[L \cdot R; \ast]}(a \cdot b) = L(b) \cdot R(b),
\]

and it contains an element \( f_{[L \cdot R; \ast]} \) which acts on this fibre as

\[
f_{[L \cdot R; \ast]}(a \cdot b) = L(a) \cdot R(a).
\]

**Proof.** Recall we assume that \( \theta \) is simplified, so that \( \theta_0 = \theta_{\ell - 1} = 1 \).

Let \( n \) be such that \( L \cdot R = (\theta^n)_{v-1} \cdot (\theta^n)_v \), for some \( 1 \leq v \leq \ell^n - 1 \). Let \( a \cdot b \) be a fixed point. Then the two-letter word \( \sigma^n(a \cdot b)_{[v-1,0]} \) is \( (\theta^n)_{v-1}(b)(\theta^n)_v(b) \). Furthermore, the expansion of \( \theta^k \theta^n \) contains \( \theta^k (\theta^n)_{i-1} (\theta^k (\theta^n)_i \) at positions \([\ell^k (i-2), \ell^k i - 1]\). Hence

\[
\sigma^{\ell^k}(a \cdot b)_{[\ell^k,v-1]} = \theta^k L(b) \theta^k R(b).
\]
It follows that
\[
\sigma^{v\ell^k}(a \cdot b) \xrightarrow{k \to +\infty} L(b) \cdot R(b)
\]
in the topology of \(X_\theta\). By compactness there exists \(f_{[L \cdot R; +]} \in E(X_\theta)\) which agrees with the map \(a \cdot b \mapsto L(b) \cdot R(b)\) on the singular fibre. It follows from the exact sequence (2.7) that an element of \(E(X_\theta)\) either preserves all \(\pi\)-fibres or none. Hence \(f_{[L \cdot R; +]} \in E(X_\theta)^\text{fib}\).

To construct elements in \(E(X_\theta)\) which acts like \(a \cdot b \mapsto L(a) \cdot R(a)\) on the singular fibre, we take \(v' = v - \ell^n\) with \(n\) and \(v\) as above. Then the two-letter word \(\sigma^{v'}(a \cdot b)_{[-1,0]}\) is \(L(a) \cdot R(a)\) and, similarly, we find
\[
\sigma^{v'\ell^k}(a \cdot b) \xrightarrow{k \to +\infty} L(a) \cdot R(a).
\]

By compactness we find the required map \(f_{[L \cdot R; -]}\). 

Let us denote the restriction of \(f_{[L \cdot R; \varepsilon]}\) to \(\pi^{-1}(0)\) by \([L \cdot R; \varepsilon]\) and set
\[
G^{(2)}_{\pm} := \{[L \cdot R; \varepsilon] : L \cdot R \in G^{(2)}, \varepsilon \in \{\pm\}\}.
\]

It is easily checked that different elements of \(G^{(2)}_{\pm}\) define different maps on \(\pi^{-1}(0)\).

**Proposition 4.9.** For any \(\varphi \in M_0^{\text{fib}}(X_\theta)\) there exist \(L \cdot R \in G^{(2)}\) and \(\varepsilon = \pm\) such that \(\varphi = [L \cdot R; \varepsilon]\).

**Proof.** Any \(\varphi \in M_0^{\text{fib}}(X_\theta) \subset E_0^{\text{fib}}(X_\theta)\) is the restriction of a function \(f \in E^{\text{fib}}(X_\theta)\) to \(\pi^{-1}(0)\). We consider first the case that this function belongs to \(E(X, \mathbb{Z}^+)\), that is, \(f\) is a pointwise limit of a generalised sequence \((\sigma^v)_i\) with \(v_i > 0\) (the inequality is strict as \(f \neq \text{Id}\)). Note that \(\varphi(a \cdot b)_{[-1,0]}\) is an open neighbourhood of \(\varphi(a \cdot b)\). Thus given \(a \cdot b \in \pi^{-1}(0)\), there exists an \(i_0\) such that \(\varphi(a \cdot b)_{[-1,0]} = \sigma^v(a \cdot b)_{[-1,0]}\) for \(i \geq i_0\). As \(\pi^{-1}(0)\) is finite there exists a \(v > 0\) such that \(\varphi(a \cdot b)_{[-1,0]} = \sigma^v(a \cdot b)_{[-1,0]}\) for all \(a \cdot b \in \pi^{-1}(0)\). Let \(L = (\theta^n)_{\ell^n-1}\) and \(R = (\theta^n)_{\ell^n}\), where \(\ell^n \geq v\). Then, for all \(a \cdot b \in \pi^{-1}(0)\), we have \(\varphi(a \cdot b)_{[-1,0]} = L(b) \cdot R(b)_{[-1,0]}\). Since the fixed points are uniquely determined by their two-letter word on \([-1,0]\), the map \(\varphi\) is given by \(a \cdot b \mapsto L(b) \cdot R(b)\). It is thus the restriction of \(f_{[L \cdot R; \varepsilon]}\) to \(\pi^{-1}(0)\).

If \(f \in E^-(X_\theta)\), we argue similarly: there exists a \(v < 0\) such that, for all \(a \cdot b \in \pi^{-1}(0)\), we have \(\varphi(a \cdot b)_{[-1,0]} = \sigma^v(a \cdot b)_{[-1,0]}\). Then we take \(L = (\theta^n)_{\ell^n-v-1}\) and \(R = (\theta^n)_{\ell^n}\), where \(\ell^n \geq v\). This leads to \(\varphi(a \cdot b)_{[-1,0]} = L(a) \cdot (\varphi(a \cdot b)_{[-1,0]}\) for all \(a \cdot b \in \pi^{-1}(0)\), and we conclude that \(\varphi\) is the restriction of \(f_{[L \cdot R; \varepsilon]}\) to \(\pi^{-1}(0)\). 

We can compute the compositions of elements of \(G^{(2)}_{\pm}\), for example,
\[
[L \cdot R; +][L' \cdot R'; +](a \cdot b) = [L \cdot R; +](L'(b) \cdot R'(b)) = LR'(b) \cdot RR'(b) = [LR', RR', +](a \cdot b)
\]
and likewise
\[
[L \cdot R; +][L' \cdot R'; -](a \cdot b) = [L \cdot R; +](L'(a) \cdot R'(a)) = LR'(a) \cdot RR'(a) = [LR' \cdot RR'; -](a \cdot b).
\]

In this way, we get the following.

**Corollary 4.10.** \(M^{\text{fib}}_0(X_\theta) = G^{(2)}_0\) with product given by
\[
[L \cdot R; +][L' \cdot R'; +] = [LR' \cdot RR'; +],
[L \cdot R; -][L' \cdot R'; -] = [LL' \cdot RL'; -],
[L \cdot R; +][L' \cdot R'; -] = [LR' \cdot RR'; -],
[L \cdot R; -][L' \cdot R'; +] = [LL' \cdot RL'; +].
\]

**Proof.** Combine Propositions 4.8 and 4.9 together with the fact that all \([L \cdot R; \varepsilon]\) act differently to see that there is a one-to-one correspondence between the elements of \(M^{\text{fib}}_0(X_\theta)\) and \(G^{(2)}_0\). The form of the product is a direct calculation along the lines above. 

**Proof of Theorem 4.6.** Given the result of Corollary 4.10, it remains to show that \(G^{(2)}_\pm\) is isomorphic to \(M[G_\theta, I_\theta, \{\pm\}; A]\) for any fixed choice of \(g_0 = R_0 L_0^{-1} \in I_\theta\). Recall that, as a set, \(M[G_\theta, I_\theta, \{\pm\}; A] = I_\theta \times G_\theta \times \{\pm\}\). Consider the map
\[
G^{(2)}_\pm \ni [L \cdot R; \varepsilon] \mapsto \begin{cases} (RL^{-1}, RL_0 R_0^{-1}, \varepsilon) & \text{if } \varepsilon = -, \\ (RL^{-1}, R, \varepsilon) & \text{if } \varepsilon = +. \end{cases} \tag{4.4}
\]

Its injectivity is clear and its surjectivity is equivalent to Lemma 4.7. A direct calculation shows that it preserves the product structures.

The Rees structure group of \(M[G_\theta, I_\theta, \{\pm\}; A]\) is \(G_\theta\), the structure group of \(\theta\). It is related to the structure group \(G_\pi\) of the factor \(\pi : (X_\theta, \sigma) \to (Z_\varepsilon, (+1))\) as follows: the choice of \(g_0 \in I_\theta\) to define the normalised matrix semigroup corresponds to a choice of a minimal idempotent \(e\) of \(E^{\text{fib}}_0(X_\theta, Z^+)\). Then we may view \(G_\pi = e E^{\text{fib}}_0 e\). \(G_\pi\) is thus a permutation of \(e^{-1}(0)\) and if we identify \(e^{-1}(0)\) via \(a \cdot b \mapsto b\) with \(A\) then we obtain \(G_\theta\).

We remark that an idempotent \(e \in E^{\text{fib}}_0(X_\theta, Z^+)\) has the form \(e = (i, 1, +), i \in I_\theta\), so that \(e M^{\text{fib}}_0(X_\theta) e = \{i\} \times G_\theta \times \{+\}\) which is isomorphic to \(G_\theta\) via the projection onto the middle component.

**Example 4.11.** Consider the substitution \(\theta\) given by
\[
\begin{align*}
a & \mapsto abaa \\
b & \mapsto bacb \phantom{.} \\
c & \mapsto ccbc
\end{align*}
\]
We use the notation $\left( \begin{array}{c} \alpha \\ \beta \\ \gamma \end{array} \right)$ to denote the bijection that sends $a$ to $\alpha$, $b$ to $\beta$, and $c$ to $\gamma$. The expansion of $\theta$ is $\theta_0|\theta_1|\theta_2|\theta_3$ with $\theta_0 = \theta_3 = 1 = \left( \begin{array}{c} a \\ b \\ c \end{array} \right)$, while $\theta_1 = \left( \begin{array}{c} b \\ a \\ c \end{array} \right)$ and $\theta_2 = \left( \begin{array}{c} a \\ c \\ b \end{array} \right)$ are two transpositions. We quickly find that

$$I_\theta = \left\{ \theta_1 \theta_0^{-1} = \left( \begin{array}{c} b \\ a \\ c \end{array} \right), \ \theta_2 \theta_1^{-1} = \left( \begin{array}{c} c \\ a \\ b \end{array} \right), \ \theta_3 \theta_2^{-1} = \left( \begin{array}{c} a \\ c \\ b \end{array} \right) \right\}.$$

Clearly, $I_\theta$ generates $G_\theta = S_3$. The normalised sandwich matrix is

$$A = \begin{pmatrix} 1 & 1 & 1 \\ 1 & \tau_1 & \tau_2 \end{pmatrix},$$

where $\tau_1 = \theta_1 \theta_0^{-1} \theta_1 \theta_2^{-1} = \theta_2$ and $\tau_2 = \theta_2 \theta_1^{-1} \theta_2 \theta_3^{-1} = \theta_2 \theta_1 \theta_2$ are transpositions. $\mathcal{M}_0^{\text{fib}}(X_\theta) = M[S_3, I_\theta, \{\pm\}; A]$ has 2 minimal left ideals each of which contains 18 elements, and 3 minimal right ideals each of which contains 12 elements.

We note that $(X_\theta, \sigma)$ is not an AI-extension of $(\mathbb{Z}_4, +1)$; this can be seen by applying Martin’s criterion, which we do not describe here (see [22] or [25] for definitions and details); it suffices to note that $\theta$ admits seven two-letter words and has height one, and that the set of two-letter words cannot be partitioned into sets of size three, creating an obstruction. Thus the techniques of [25] do not apply.

### 4.4. The full semigroup $E(X_\theta)$

We now combine Theorem 3.6 with our results from Section 3 to determine $E^{\text{fib}}(X_\theta)$ and, as far as possible, $E(X_\theta)$. We consider first the simpler case in which $\mathcal{M}_0^{\text{fib}}(X_\theta)$ is generated by its idempotents.

**Theorem 4.12.** Let $\theta$ be a primitive aperiodic bijective substitution and suppose that its structural semigroup $\mathcal{M}_0^{\text{fib}}(X_\theta)$ is generated by its idempotents. Then $E^{\text{fib}}(X_\theta)$ is topologically isomorphic to

$$E^{\text{fib}}(X_\theta) \cong \left( \mathcal{M}_0^{\text{fib}}(X_\theta) \cup \{\text{Id}\} \right) \times \prod_{[z] \in \mathbb{Z}/\mathbb{Z}} G_\theta.$$ 

Using the sets $I_\theta$, $\{\pm\}$ and the sandwich matrix $A$ from normalised Rees matrix form $M[G_\theta; I_\theta, \{\pm\}; A]$ for $\mathcal{M}_0^{\text{fib}}(X_\theta)$, one can also express this as follows: $E^{\text{fib}}(X_\theta) \setminus \{\text{Id}\}$ is completely simple and topologically isomorphic to

$$E^{\text{fib}}(X_\theta) \setminus \{\text{Id}\} \cong M[G_\theta; I_\theta, \{\pm\}; A], \quad G_\theta^{\text{fib}} = G_\theta^{\mathbb{Z}/\mathbb{Z}}.$$

Here an entry $a_{\lambda, g}$ of $A$ is identified with the function $f \in G_\theta^{\text{fib}}$ which satisfies $f(0) = a_{\lambda, g}$ and $f(z) = 1$ for regular $z$.

Furthermore, $E(X_\theta) \setminus \mathbb{Z}$ is algebraically isomorphic to

$$E(X_\theta) \setminus \mathbb{Z} \cong M[G_0; I_\theta, \{\pm\}; A], \quad G_\theta = G_\theta^{\text{fib}} \rtimes \mathbb{Z}.$$
where $A$ is understood to take values in the subgroup $G_\theta \times \{1\}^{\mathbb{Z}_\ell/\mathbb{Z}\setminus\{0\}} \times \{0\}$ of $G_\theta^\mathbb{Z}_\ell/\mathbb{Z} \rtimes \mathbb{Z}_\ell$.

**Proof.** As $E^{\text{fib}}(X_\theta)_0 = M_0^{\text{fib}}(X_\theta) \cup \{\text{Id}\}$, it is generated by its idempotents. Furthermore, the minimal rank $r_\pi$ is equal to $|A|$. The first expression for $E^{\text{fib}}(X_\theta)$ is thus a direct application of Corollary 3.11. The second expression corresponds to (3.4). The last statement follows from Corollary 3.14.

While the isomorphism between $E(X_\theta)\setminus\mathbb{Z}$ and $M[G_\theta^\mathbb{Z}_\ell/\mathbb{Z} \rtimes \mathbb{Z}_\ell; I_\theta, \{\pm\}; A]$ is not continuous when $G_\theta^\mathbb{Z}_\ell/\mathbb{Z} \rtimes \mathbb{Z}_\ell$ is equipped with the product topology, Theorem 4.12 makes clear where the non-tameness comes from: whereas the restrictions of $E^{\text{fib}}(X_\theta)$ to individual fibres are finite semigroups, it is the fact that the structure group of its kernel consists of all possible functions over the orbit space which implies that the cardinality of $E^{\text{fib}}(X_\theta)$, and hence of $E(X_\theta)$, is larger than that of the continuum.

### 4.5. Height

The assumption of the last theorem, namely that $M_0^{\text{fib}}(X_\theta)$ is generated by its idempotents, is not always satisfied. To treat the other cases we introduce a new notion of height.

Let $I_\theta$ be the $R$-set of a bijective substitution $\theta$ and let $\Gamma_\theta$ be the group generated by $\{gh^{-1} : g, h \in I_\theta\}$. We have seen in Lemma 2.3 that $\Gamma_\theta$ is the Rees structure group of the subsemigroup generated by the idempotents of $M_0^{\text{fib}}(X_\theta)$. If $I_\theta$ contains 1, then $\Gamma_\theta$ contains $I_\theta$ and therefore coincides with $G_\theta$, and consequently $M_0^{\text{fib}}(X_\theta)$ is generated by its idempotents. However, $\Gamma_\theta$ need not even be a normal subgroup of $G_\theta$; see Section 6.2 for an example.

**Lemma 4.13.** Let $\widetilde{\Gamma}_\theta$ be a normal subgroup of $G_\theta$ which contains the little structure group $\Gamma_\theta$. Denote by $\phi : G_\theta \rightarrow G_\theta/\widetilde{\Gamma}_\theta$ the canonical projection. Then $\phi(g_1) = \phi(g_2)$ for any two elements of $I_\theta$. In particular, $G_\theta/\widetilde{\Gamma}_\theta$ is a finite cyclic group.

**Proof.** If $\phi(g_1) \neq \phi(g_2)$ for two elements of $I_\theta$, then $\phi(g_1g_2^{-1}) \neq 1$. But $g_1g_2^{-1} \in \Gamma_\theta \subseteq \ker \phi$. Since $I_\theta$ generates $G_\theta$, the class of $I_\theta$ is a generator of $G_\theta/\widetilde{\Gamma}_\theta$. ■

We denote the order of $G_\theta/\widetilde{\Gamma}_\theta$ by $\widehat{\ell}$. Note that $\widehat{\ell}$ must divide any $\nu > 0$ for which $(\theta^n)_\nu \in \widetilde{\Gamma}_\theta$ (here $n$ is large enough such that $\nu \leq \ell^n$). Indeed, $(\theta^n)_\nu(\theta^n)_0^{-1}$ is a product of $\nu$ elements of $I_\theta$ and so its image in $G_\theta/\widetilde{\Gamma}_\theta$ is $\nu$ times the generator of $G_\theta/\widetilde{\Gamma}_\theta$. In particular, $\widehat{\ell}$ divides $\ell - 1$.

#### 4.5.1. Classical height.

To better understand the meaning of the quantity $\widehat{\ell}$, we recall the notion of height which occurs in the context of constant length substitutions.

The equicontinuous factor $\mathbb{Z}_\ell$ which we have described above for a primitive aperiodic substitution $\theta$ of constant length is not always the maximal equicontinuous factor, i.e., there might be an intermediate equicontinuous factor $(X_{\max}, +g)$ between $(X_\theta, \sigma)$ and $(\mathbb{Z}_\ell, +1)$. The relevant quantity which governs this is the height of the substitution. In view of what follows, we refer to it here as its classical height. This is a natural number.
arising as the height of a tower comprising a Kakutani–Rohlin model for the dynamical system and shows up also in the spectral analysis. It can be computed as follows. Consider a one-sided fixed point \( u = u_0 u_1 \cdots \) of \( \theta \). The (classical) height \( h_{cl} \) of \( \theta \) is defined as

\[
h_{cl}(\theta) := \max \left\{ n \geq 1 : \gcd(n, \ell) = 1, \ n \mid \gcd(k : u_k = u_0) \right\}. \tag{4.5}
\]

For primitive substitutions, it turns out to be independent of the choice of \( u \). The following result was shown by Dekking [11], with partial results by Kamae [20] and Martin [22].

**Theorem 4.14.** Let \( \theta \) be a primitive aperiodic substitution of length \( \ell \) and classical height \( h_{cl} \). Then the maximal equicontinuous factor of \((X_\theta, \sigma)\) is \((\mathbb{Z}_\ell \times \mathbb{Z}/h_{cl} \mathbb{Z}, (+1) \times (+1))\).

The theorem says that \( \frac{1}{h_{cl}} \) corresponds to a topological eigenvalue of the dynamical system \((X_\theta, \sigma)\) which does not already occur in the spectrum of \((\mathbb{Z}_\ell, +1)\). It moreover implies that the surjection \( \tilde{\pi} \) in (2.7) factors through \( \mathbb{Z}/h_{cl} \mathbb{Z} \times \mathbb{Z}_\ell \),

\[
E(X_\theta) \twoheadrightarrow \mathbb{Z}/h_{cl} \mathbb{Z} \times \mathbb{Z}_\ell \twoheadrightarrow \mathbb{Z}_\ell,
\]

and therefore leads to a continuous surjective semigroup morphism

\[
E_{\text{fib}}(X_\theta) \twoheadrightarrow \mathbb{Z}/h_{cl} \mathbb{Z}.
\]

Stated differently, \( E_{\text{fib}}(X_\theta) \) is a \( \mathbb{Z}/h_{cl} \mathbb{Z} \)-graded right-topological semigroup.

A more detailed analysis yields the following picture. Let \( u \) be any one-sided fixed point of \( \theta \). For \( a \in A \), let \( i_u(a) = \min\{k : u_k = a\} \). We claim that the set \( \{n \in \mathbb{N} : u_n = a\} \) of occurrences of \( a \) in \( u \) is contained in \( i_u(a) + h_{cl} \mathbb{N} \), where \( h_{cl} \) is as in (4.5). Suppose that \( a \) occurs at indices \( i \) and \( j \) in \( u \). Let \( v \) be the one-sided fixed point of \( \theta \) that starts with \( a \). By minimality there exists \( i_0 \in \mathbb{N}_0 \) such that we see \( a \) in \( v \) at the indices \( i_0 + i \) and \( i_0 + j \), \( a = v_{i_0+i} = v_{i_0+j} \). Recall that the classical height \( h_{cl} \) can be defined using any fixed point of \( \theta \). Taking \( v \) in place of \( u \) in the definition (4.5), we see that all indices at which we see the letter \( a \) in \( v \) are multiples of \( h_{cl} \). Thus \( h_{cl} \) divides \( i - j \), and our claim follows. In other words, we can partition the alphabet into subsets \( A_k := \{a \in A : i_u(a) \equiv k \text{ mod } h_{cl}\} \) and \( \sigma(A_k) = A_{k+1} \). Note also that if \( \theta \) is simplified, then \( \{k : u_k = u_0\} \) contains \( \ell - 1 \) and hence the classical height must divide \( \ell - 1 \). In Lemma 4.15 and Theorem 4.17, we extend this partition to \( G_\theta \) and \( E(X_\theta) \).

**Lemma 4.15.** Let \( \theta \) be a primitive aperiodic bijective substitution with structure group \( G_\theta \). If \( \theta \) has classical height \( h_{cl} \), then there is a surjective group homomorphism \( \phi_{cl} : G_\theta \rightarrow \mathbb{Z}/h_{cl} \mathbb{Z} \) such that for all \( g \in I_\theta \) one has \( \phi_{cl}(g) = 1 \).

**Proof.** We may assume that \( \theta \) is simplified and hence the height \( h_{cl} \) divides \( \ell - 1 \). Fix an arbitrary one-sided fixed point \( u = u_0 u_1 \cdots \) of \( \theta \). For \( a \in A \), let \( i_u(a) = \min\{k : u_k = a\} \); we have seen that \( \{n \in \mathbb{N} : u_n = a\} \) is contained in \( i_u(a) + h_{cl} \mathbb{N} \). We now understand \( k \) and \( i_u(a) \) as an index modulo \( h_{cl} \). As \( \theta_j(u_k) = u_{\ell k+j} \), we see that \( i_u(\theta_j(a)) - i_u(a) \equiv (\ell - 1)i_u(a) + j \equiv j \). Since the height must divide \( \ell - 1 \), we find \( (\ell - 1)i_u(a) + j \equiv j \). Hence \( i_u(\theta_j(a)) - i_u(a) \) does not depend on \( a \) and so \( \phi_{cl}(\theta_j) := i_u(\theta_j(a)) - i_u(a) \) is
a well-defined map from \( \{ \theta_j, j \geq 0 \} \) to \( \mathbb{Z}/h_{\ell}\mathbb{Z} \). We compute \( i_u(\theta_j; \theta_j(a)) \equiv j' + \ell(j + \ell i_u(a)) \equiv j' + j + i_u(a) \) and thus see that \( \phi_{\ell} \) is multiplicative. It hence induces a surjective group homomorphism \( \phi_{\ell} : G_{\theta} \to \mathbb{Z}/h_{\ell}\mathbb{Z} \). Clearly, \( \phi_{\ell}(\theta_j^{-1}) = 1 \).

**4.5.2. Generalised height.** To discuss generalised height, we introduce the maps \( \text{ev}_0 \) and \( \text{ev}_0^z \), where

\[
\text{ev}_0 : X_{\theta} \to \mathcal{A}, \quad \text{ev}_0(x) := x_0
\]

reads the letter on 0 of \( x \) and \( \text{ev}_0^z := \text{ev}_0|_{E\pi^{-1}(z)} \) is the restriction of \( \text{ev}_0 \) to the subset \( E\pi^{-1}(z) \) of the fibre over \( z \). Here again, \( e \) is a chosen minimal idempotent, but we take it from \( E(X_{\theta}, \mathbb{Z}^+) \). Clearly, if \( z \) is regular, then \( e\pi^{-1}(z) = \pi^{-1}(z) \). Note that if \( z \in \mathbb{Z}^- \), then \( \text{ev}_0(x) = \text{ev}_0(e(x)) \) because \( e \) does not affect the right infinite part of a fixed point. \( \text{ev}_0^z \) is a bijection which we will use below to identify \( e\pi^{-1}(z) \) with \( \mathcal{A} \). As we already mentioned, conjugation with \( \text{ev}_0^0 \) identifies \( G_{\pi} \) with \( G_{\theta} \) and \( \Gamma_{\pi} \) with \( \Gamma_{\theta} \).

**Lemma 4.16.** Let \( f \in E(X_{\theta}, \mathbb{Z}^+) \) and \( z \in \mathbb{Z}_{<} \backslash \mathbb{Z}_{\ell}^{-} \). There exists \( f_z \in G_{\theta} \) such that for all \( x \in \pi^{-1}(z) \) one has \( \text{ev}_0(f(x)) = f_z(x_0) \).

**Proof.** We first show the result for \( z = n \in \mathbb{Z}^+ \) and \( f = \sigma^n, m \geq 0 \). Then \( x = \sigma^n(a,b) \) for some fixed point \( a,b \) and \( n \geq 0 \). It follows that \( \sigma^n(x) = (\theta^k)^{n+m}(\theta^k)^{-1}(x_0) \) for \( x \in \pi^{-1}(z) \) and all \( k \) with \( \ell k > n + m \). Thus for \( z = n \) we can take \( \sigma^n_z = (\theta^k)^{n+m}(\theta^k)^{-1} \).

Next suppose \( z \) is regular and \( f = \sigma^m \). Since \( (X, \sigma) \) is forward minimal, there is \( h \in E(X_{\theta}, \mathbb{Z}^+) \) with \( \pi(h) = z \), where \( h \) is the limit of some generalised sequence \( \sigma^{n_v} \) and \( \pi^{-1}(z) = h(\pi^{-1}(0)) \). Let \( x \in \pi^{-1}(z) \), i.e., \( x = h(a,b) \) for some fixed point \( a,b \). By continuity of \( \sigma \) and \( \text{ev}_0 \) we have

\[
\text{ev}_0 \circ \sigma^m \circ h(a,b) = \lim_{v} \text{ev}_0 \circ \sigma^{m+n_v}(a,b)
\]

and since \( \pi^{-1}(0) \) is finite there exists \( v_0 \) such that for all \( v \geq v_0 \) and all \( a,b \in \pi^{-1}(z) \),

\[
\lim_{v} \text{ev}_0 \circ \sigma^{m+n_v}(a,b) = \text{ev}_0 \circ \sigma^{m+n_v}(a,b).
\]

Hence

\[
\sigma^m_z = \sigma^{m}_{n_v}
\]

once \( v \geq v_0 \).

Now let \( f \in E(X_{\theta}, \mathbb{Z}^+) \) and \( z \in \mathbb{Z}_{<} \backslash \mathbb{Z}_{\ell}^{-} \). \( f \) is the limit of some generalised sequence \( \sigma^{n_\mu} \). We have

\[
\text{ev}_0 \circ f(x) = \lim_{\mu} \text{ev}_0 \circ \sigma^{n_\mu}(x).
\]

As \( \pi^{-1}(z) \) is finite, there exists \( \mu_0 \) such that for all \( \mu \geq \mu_0 \) and all \( x \in \pi^{-1}(z) \),

\[
\lim_{\mu} \text{ev}_0 \circ \sigma^{n_\mu}(x) = \text{ev}_0 \circ \sigma^{n_\mu}(x). \quad \text{Hence} \quad f_z = \sigma^{n_\mu}z \quad \text{once} \quad \mu \geq \mu_0.
\]

**Theorem 4.17.** Let \( \Gamma_{\theta} \) be a normal subgroup of \( G_{\theta} \) which contains the little structure group \( \Gamma_{\theta} \). There exists a continuous surjective semigroup morphism

\[
\eta : E(X_{\theta}, \mathbb{Z}^+) \to G_{\theta}/\Gamma_{\theta} \cong \mathbb{Z}/h\mathbb{Z}
\]

such that \( \eta(\sigma f) = \eta(f) + 1 \). In other words, \( \frac{1}{h} \) is a topological eigenvalue of the dynamical system \( (E(X_{\theta}, \mathbb{Z}^+), \lambda_{\sigma}) \), where \( \lambda_{\sigma}(f) := \sigma \circ f \).
Proof. By Lemma 4.16, given $z \in \mathbb{Z}_\ell \setminus \mathbb{Z}^-$ we can assign to any $f \in E(X_\theta, \mathbb{Z}^+)$ a map $f_z \in I_\theta$. It depends on $z$ but since two elements of $I_\theta$ differ by an element of $\Gamma_\theta$ the class $f_z \Gamma_\theta$ is independent of $z$. We can therefore define

$$\eta(f) := f_z \Gamma_\theta.$$ 

We show that $\eta$ is locally constant. For that we consider the following neighbourhood of $f$: given $z \notin \mathbb{Z}^-$, let

$$V = \{ f' \in E(X_\theta, \mathbb{Z}^+) : ev_0(f(x)) = ev_0(f'(x)) \forall x \in \pi^{-1}(z) \}.$$ 

Then, if $f' \in V$, we must have $f_z = f'_z$ and hence $\eta(f) = \eta(f')$. Hence $\eta$ is locally constant, so continuous. It is immediate that $\eta(\sigma f) = \eta(f) + 1$. By continuity we obtain $\eta(f_1 f_2) = \eta(f_1) + \eta(f_2)$.

Finally, $e^{2\pi i \eta}$ is a continuous eigenfunction for the eigenvalue $\frac{1}{\tilde{h}}$. \hfill \blacksquare

We denote the elements of degree $\ell$ in $\mathcal{M}_0^{\text{fib}}(X_\theta, \mathbb{Z}^+) \simeq I_\theta \times G_\theta \times \{+\}$. The latter can be easily obtained using the bijection (4.4) between $G_\theta^2$ and $I_\theta \times G_\theta \times \{+\}$; it is given by $\eta : I_\theta \times G_\theta \times \{+\} \to G_\theta / \Gamma_\theta$.

$$\eta(i, g, +) = g \Gamma_\theta.$$ 

In particular, as it should be, idempotents have degree 0.

As an aside, we remark that the grading $\eta$ can be extended to all of $E(X_\theta)$. We can repeat the above with $E(X_\theta, \mathbb{Z}^-)$ while exchanging $\sigma$ with $\sigma^{-1}$ and $I_\theta$ with $I_\theta^{-1}$. One then finds that $\eta(f_{(\sigma^n)_{v=1}}(\sigma^n)_{v=1}) = v - 1$ modulo $\tilde{h}$ and $\eta(i, g, -) = g \Gamma_\theta$.

The grading of $E(X_\theta, \mathbb{Z}^+)$ restricts to a grading of the group $\mathcal{G}_0 = eE(X_\theta, \mathbb{Z}^+)e$. We denote the elements of degree $k$ by $\mathcal{G}_{qk} := \eta^{-1}(\{k\}) \cap \mathcal{G}_0$. Thus $\mathcal{G}_0 = \bigcup_{k \in \mathbb{Z}/\tilde{h} \mathbb{Z}} \mathcal{G}_{qk}$ with $\mathcal{G}_{qk} \mathcal{G}_{qk+l} = \mathcal{G}_{qk+l}$ and $\mathcal{G}_{qk} = \mathcal{G}_{qk}$ for any choice of element $\ell \in \mathcal{G}_{q1}$. Similarly, the grading restricts to $\mathcal{G}_{0}^{\text{fib}}$, the structure group of the kernel of $E_{0}^{\text{fib}}$.

Recall the definition (3.2) of $\mathcal{T}$ as the subsemigroup of elements of $E_{0}^{\text{fib}}$ which act trivially on all regular fibres. Since we have only one orbit of singular fibres, its restriction $\mathcal{T}_0$ to the fibre at $0 \in \mathbb{Z}_\ell$ is faithful and $e\mathcal{T} e$ is isomorphic to $e\mathcal{T}_0 e$. We identify $e \pi(z)$ with $\mathcal{A}$ through the restricted evaluation map $ev_0^\phi : e \pi(z) \to \mathcal{A}$. Define $\mathcal{T}_0 := ev_0^\phi e\mathcal{T}_0 e(ev_0^\phi)^{-1}$, a subgroup of the group of bijections of $\mathcal{A}$. We now consider the situation in which $\Gamma_\theta$ is a subgroup of $\mathcal{T}_0 = ev_0^\phi e\mathcal{T}_0 e(ev_0^\phi)^{-1}$ and define

$$\text{Cov}(\Gamma_\theta) := \{ f \in e \text{ Cov } e : (\Phi_0^\phi)^{-1}(f(z)) \in (ev_0^\phi)^{-1} \Gamma_\theta ev_0^\phi \forall z \in \mathbb{Z}_\ell \}.$$ 

This group is independent of the choice of lift to define $\Phi_0^\phi$, as $\Gamma_\theta$ is normal in $G_\theta$. 
Proposition 4.18. Let $\Gamma_\theta$ be a normal subgroup of $G_\theta$ which contains $\Gamma_\theta$ and is contained in $T_\theta$. Then, w.r.t. the grading defined by $\Gamma_\theta$, one has the inclusion of groups

$$G_\theta^{fib} \subset \text{Cov}(\Gamma_\theta).$$

Proof. Given $f \in G_\theta^{fib}$, we have $\eta(f) = 0$ if and only if, for all $z \in Z_{\ell} \setminus Z^-$, we have $f_z \in \Gamma_\theta$. Note that, with $\tilde{f}$ defined as in (2.4), $f_z \circ ev^z_0 = ev^z_0 \circ \tilde{f}(z)$. Moreover, if $h \in E(\mathbb{Z}^+)$, then $h_z \circ ev^z_0 = ev^{z+\pi_+(h)}_0 \circ h|_{\pi^{-1}(z)}$. It follows from Lemma 4.16 that

$$ev^{z+\pi_+(h)}_0 \circ h|_{\pi^{-1}(z)} \circ (ev^z_0)^{-1} \in G_\theta.$$

We apply this to $h = s(z)$, the lift of $z$, to see that $g := ev^z_0 \circ s(z)|_{\pi^{-1}(0)}(ev^0_0)^{-1} \in G_\theta$. Now

$$\Phi_0^{z-1}(\tilde{f}(z)) = s(z)^{-1} \tilde{f}(z)s(z) = s(z)^{-1} \circ (ev^z_0)^{-1} \circ f_z \circ ev^z_0 \circ s(z) \in (ev^0_0)^{-1} \circ g^{-1} \Gamma_\theta g \circ ev^0_0 = (ev^0_0)^{-1} \circ \Gamma_\theta \circ ev^0_0$$

as $\Gamma_\theta$ is normal in $G_\theta$. Thus $f \in \text{Cov}(\Gamma_\theta)$. \hfill $\blacksquare$

Definition 4.19. The normal completion $\bar{\Gamma}_\theta$ of the little structure group $\Gamma_\theta$ is the smallest normal subgroup of $G_\theta$ which contains $\Gamma_\theta$. The generalised height $h$ of a primitive aperiodic bijective substitution is the order of $G_\theta/\bar{\Gamma}_\theta$.

Proposition 4.20. Generalised height must be at least as large as classical height.

Proof. Recall the quotient map $\phi_{cl} : G_\theta \to \mathbb{Z}/h_{cl}\mathbb{Z}$ from Lemma 4.15. It satisfies $\phi_{cl}(\Gamma_\theta) = 0$. As $\bar{\Gamma}_\theta$ is generated by elements of the form $ghg^{-1}$ with $h \in \Gamma_\theta$ and $g \in G_\theta$ we have $\phi_{cl}(\bar{\Gamma}_\theta) = 0$ and hence $G_\theta/\bar{\Gamma}_\theta$ factors onto $\mathbb{Z}/h_{cl}\mathbb{Z}$.

In Section 6.2, we provide an example with trivial classical height but non-trivial generalised height.

Proposition 4.21. $\bar{\Gamma}_\theta = T_\theta$ and

$$G_\theta^{fib} = \text{Cov}(\bar{\Gamma}_\theta) \cong \mathbb{Z}_{\ell}/\mathbb{Z}.$$

Proof. By Theorem 3.6 we have the inclusion of groups $\text{Cov}(T_\theta) = e\text{Cov}(\mathbb{Z}/h_{cl}\mathbb{Z}) \leq eG_\theta^{fib} = G_\theta^{fib}$. Hence, by Proposition 4.18, $\text{Cov}(T_\theta)$ is a subgroup of $\bigcup_{k \in \mathbb{Z}/h_{cl}\mathbb{Z}} \hat{f}^k \text{Cov}(\bar{\Gamma}_\theta)$, where $\hat{f}$ is some element from $G_\theta^{fib}$. Since $s(z)$ and $s(z)^{-1}$ have opposite degree, $(\Phi_0^{z-1}(\tilde{f}(z)))_{\bar{\Gamma}_\theta} \in G_\theta/\bar{\Gamma}_\theta$ must be the generator of $G_\theta/\bar{\Gamma}_\theta$ for all $z$. Hence, for any $f \in \text{Cov}(T_\theta), (\Phi_0^{z-1}(\tilde{f}(z)))_{\bar{\Gamma}_\theta} \in G_\theta/\bar{\Gamma}_\theta$ is constant in $z$. This is possible only if $T_\theta$ is a subgroup of $\bar{\Gamma}_\theta$. If that is the case, then $\text{Cov}(T_\theta) = G_\theta^{fib}$, again by Proposition 4.18.

The covariance condition says that a function $\tilde{f} \in \text{Cov}$ is determined on the $\mathbb{Z}$-orbit of a point $z \in Z_{\ell}$ by its value on $z$. We may hence choose for each $\mathbb{Z}$-orbit $[z] \in Z_{\ell}/\mathbb{Z}$ a representative $z$ and then obtain a bijection from $\text{Cov}(\bar{\Gamma}_\theta)$ to $\bar{\Gamma}_\theta$-valued functions over the orbit space $Z_{\ell}/\mathbb{Z}$ by restricting $\tilde{f}$ to the chosen representatives. This bijection is, of course, not canonical as it involves an uncountable choice of representatives, but it is a topological isomorphism of semigroups. \hfill $\blacksquare$
We end this section with the generalisation of Theorem 4.12 to substitutions which may have non-trivial height.

**Theorem 4.22.** Let θ be a primitive aperiodic bijective substitution with generalised height ℎ. Using the sets \( I_θ, \{±\} \), and the sandwich matrix \( A \) from normalised Rees matrix form \( M[G_θ; I_θ, \{±\}; A] \) for \( M^{fib}_θ(X_θ) \), \( E^{fib}(X_θ)\backslash\{\text{Id}\} \) is topologically isomorphic to

\[
E^{fib}(X_θ)\backslash\{\text{Id}\} \cong M[M^{fib}_θ ; I_θ, \{±\}; A],
\]

where \( M^{fib}_θ \) is a \( \mathbb{Z}/h\mathbb{Z} \)-graded group and

\[
G^{fib}_θ = \hat{\mathfrak{f}}^k \text{Cov}(\hat{Γ}_θ)
\]

for any element \( \hat{\mathfrak{f}} \) of degree 1 of \( G^{fib}_θ \). Here an entry \( a_{λ,γ} \) of \( A \) is identified with the function \( \hat{f} \in G^{fib}_θ \) which satisfies \( \hat{f}(0) = a_{λ,γ} \) and \( \hat{f}(z) = 1 \) for regular \( z \).

If \( G_θ \) contains an element of order \( h \), then \( G^{fib}_θ \) is a semidirect product

\[
G^{fib}_θ \cong \text{Cov}(\hat{Γ}_θ) \times \mathbb{Z}/h\mathbb{Z}.
\]

Furthermore, \( E(X_θ)\backslash\mathbb{Z} \) is algebraically isomorphic to

\[
E(X_θ)\backslash\mathbb{Z} \cong M[G_θ; I_θ, \{±\}; A],
\]

where \( G_θ \) is the extension determined by \( G^{fib}_θ \) and \( A \) is understood to take values in the subgroup \( G^{fib}_θ \). If moreover generalised height is equal to classical height, then there is a split section \( s : \mathbb{Z}_ι \to G_θ \) whose image belongs to \( G_{θ0} \). In particular, one has the algebraic isomorphism

\[
G_θ \cong G^{fib}_θ \times \mathbb{Z}_ι.
\]

**Proof.** The first part follows from Proposition 4.21. It remains to show that \( G^{fib}_θ \cong \text{Cov}(\hat{Γ}_θ) \times \mathbb{Z}/h\mathbb{Z} \) provided \( G_θ \) contains an element of order \( h \). An element \( \hat{f} \in G^{fib}_θ \) with \( η(\hat{f}) = 1 \) can be constructed as follows. We saw that any \( (i_0, i, +) \in M[G_θ; I_θ, \{±\}; A] \) with \( i \in I_θ \) has degree 1. Pick \( i \in G_θ \) and let \( \hat{f} \) be the function which satisfies

\[
\hat{f}(z) := Φ^z_θ((ev_0^0)^{-1}(i_0, i, +)ev_0^0).
\]

Then \( \hat{f} \) is an element of degree 1 in \( \text{Cov}(G_θ) \). As \( Φ^z_θ \) restricts to a group isomorphism from \( eE^{fib}_θ e \) to \( E^{fib}_θ \), it preserves the order of an element and, therefore, if \( i^h = 1 \), then \( \hat{f} \) has order \( h \). In that case, \( \mathbb{Z}/h\mathbb{Z} \ni 1 \mapsto \hat{f} \in G^{fib}_θ \) induces a split section for the exact sequence

\[
G^{fib}_θ \cong G^{fib}_θ \times \mathbb{Z}/h\mathbb{Z}.
\]

The result for \( E(X_θ) \) follows from Proposition 2.6. We have seen that if \( h \) is equal to the classical height, then \( \tilde{π} \) factors through the maximal equicontinuous factor which is \( \mathbb{Z}/h\mathbb{Z} \times \mathbb{Z}_ι \). By the axiom of choice we can construct a covariant lift \( s : \mathbb{Z}_ι \to G_θ \) which factors through \( \{0\} \times \mathbb{Z}_ι \subset \mathbb{Z}/h\mathbb{Z} \times \mathbb{Z}_ι \). It hence takes values in \( G_{θ0} \). It follows that the split homomorphism \( \tilde{π} \) constructed in Proposition 3.13 also takes values in \( G_{θ0} \). Thus \( G_{θ0} \cong G^{fib}_θ \times \mathbb{Z}_ι \). This implies the last statement. □
5. The virtual automorphism group of unique singular orbit systems

In this section, we investigate the relationship between the automorphism group and the virtual automorphism group of bijective substitutional systems, as defined by Auslander and Glasner [4]. They show that an almost automorphic system is semi-regular iff it is equicontinuous. They also show that the Thue–Morse shift is semi-regular. Using our tools, in this section we will extend their result to show that bijective substitution shifts are semi-regular.

We start a little bit more generally considering minimal systems \((X, T, \sigma)\), where \(T\) is an abelian group, unless we are talking about a substitution, in which case \(T = \mathbb{Z}\).

5.1. Automorphism groups of bijective substitutions

The automorphism group \(\text{Aut}(X)\) of a dynamical system \((X, \sigma)\) is the group, under composition, of all homeomorphisms of \(X\) which commute with \(\sigma\). Since the elements of \(E(X)\) are limits of generalised sequences of powers of \(\sigma\), the automorphism group, viewed as a subset of \(X^X\), lies in the commutant of \(E(X)\). Similar to the situation of Ellis semigroups described in Section 2.7, if \((X, \sigma)\) is minimal and \(\pi : X \to Y\) is an equicontinuous factor map, then the map \(\pi_*\) from Section 2.7 is well defined on automorphisms of \(X\) inducing a group morphism \(\pi_* : \text{Aut}(X) \to \text{Aut}(Y)\); see [10]. We also have \(\text{Aut}(Y) \cong Y\) for a minimal equicontinuous system. But \(\pi_*\) is usually not surjective, although its image always contains \(T \subset Y\). We can therefore analogously define \(\text{Aut}^{\text{fib}}(X)\) as the kernel of \(\pi_*\), that is, the subgroup of automorphisms which preserve the \(\pi\)-fibres, and then determine \(\text{Aut}(X)\) through the extension \(\text{Aut}^{\text{fib}}(X) \hookrightarrow \text{Aut}(X) \twoheadrightarrow \pi_*(\text{Aut}(Y))\). Contrary to most elements of \(E^{\text{fib}}(X)\), the elements of \(\text{Aut}^{\text{fib}}(X)\) are always continuous and therefore, again by minimality, \(\text{Aut}^{\text{fib}}(X)\) is determined by its restriction to a fibre \(\pi^{-1}(y_0)\).

Furthermore, \(\text{Aut}^{\text{fib}}(X)\) must commute with \(E^{\text{fib}} \subset E^{\text{fib}}(X)e\) and therefore its restriction to \(\pi^{-1}(y_0)\) is contained in the centraliser of the structure group \(G_\pi = eE^{\text{fib}}(X)e\) in the permutation group \(S_{\pi^{-1}(y_0)}\) of the factor [23, Theorem 33]. For primitive bijective substitution shifts it can be shown that \(\text{Aut}^{\text{fib}}(X)\) exhausts that centraliser and that \(\text{Aut}(X)\) is determined by \(\text{Aut}^{\text{fib}}(X)\).

Theorem 5.1 ([21, Theorem 5]). Let \(\theta\) be a primitive aperiodic bijective substitution over the alphabet \(A\). Then \(\text{Aut}^{\text{fib}}(X_\theta)\) is isomorphic to the centraliser \(C_{S_A}(G_\theta)\) and

\[
\text{Aut}(X_\theta) \cong C_{S_A}(G_\theta) \times \mathbb{Z}.
\]

5.2. Virtual automorphism groups

We start with the two algebraic lemmas. Given a set \(X, x \in X\), and a group \(G \subseteq S_X\), the permutation group of \(X\), let \(\text{Stab}_G(x)\) denote the stabilizer of \(x\) in \(G\), let \(N_G(\text{Stab}_G(x))\) denote the normaliser of \(\text{Stab}_G(x)\) in \(G\), and let \(C_{S_X}(G)\) denote the centraliser of \(G\) in \(S_X\). The following lemma from group theory is well known but we include a proof. Recall that a group \(G\) acts transitively on \(X\) if for each pair \(x, y \in X\) there exists \(g \in G\) such that \(g(x) = y\).
**Lemma 5.2.** Let $G$ be a subgroup of the permutation group $S_X$ which acts transitively on $X$, and let $x \in X$. Then

$$N_G(\text{Stab}_G(x)) / \text{Stab}_G(x) \cong C_{S_X}(G).$$

**Proof.** Let $h \in N_G(\text{Stab}_G(x))$. We first claim that if two $f, f' \in G$ satisfy $f(x) = f'(x)$, then $fh^{-1}(x) = f'h^{-1}(x)$. Indeed, $f(x) = f'(x)$ implies $f' = fs$ for some $s \in \text{Stab}_G(x)$. Furthermore, $sh^{-1} = h^{-1}s'$ with $s'$ in $\text{Stab}_G(x)$, as $h$ normalises $\text{Stab}_G(x)$. Hence

$$fh^{-1}(x) = f'h^{-1}(s'x) = fs'h^{-1}(x) = f'h^{-1}(x).$$

Therefore the map $F : N_G(\text{Stab}_G(x)) / \text{Stab}_G(x) \rightarrow S_X$ defined by

$$F(h)(y) := fh^{-1}(x), \quad \text{for any } f \in G \text{ such that } f(x) = y$$

is well defined. We show that the map $F$ preserves the group multiplication. Let $h_1, h_2 \in N_G(\text{Stab}_G(x)) / \text{Stab}_G(x)$. Then

$$F(h_1)(F(h_2)(y)) = f_1h_1^{-1}(x), \quad \text{for any } f_1 \in G \text{ such that } f_1(x) = F(h_2)(y) \quad (5.1)$$

and $F(h_2)(y) = f_2h_2^{-1}(x)$ for any $f_2 \in G$ such that $f_2(x) = y$. In particular, $f_2(x) = f_2h_2^{-1}(x)$ so that we may take $f_1 = f_2h_2^{-1}$ in (5.1). Thus

$$F(h_1)(F(h_2)(y)) = f_2h_2^{-1}h_1^{-1}(x).$$

As $f_2(x) = y$ this is also equal to $F(h_1h_2)(y)$.

Note that if $F(h) = \text{Id}$ then $fh^{-1}(x) = f(x)$ for all $f$, which implies that $F$ is injective.

Furthermore, using our first claim again, it can be checked that $F(h)$ commutes with the elements of $\text{Stab}_G(x)$ and so the image of $F$ is contained in $C_{S_X}(G)$. To see that the image of $F$ is all of $C_{S_X}(G)$, let $\psi \in C_{S_X}(G)$. Since $G$ acts transitively, there exists $h \in G$ such that $\psi(x) = h^{-1}(x)$. Then, for $f \in G$,

$$\psi(f(x)) = f\psi(x) = fh^{-1}(x). \quad (5.2)$$

If we apply this formula to $f \in \text{Stab}_G(x)$, we get $h^{-1}(x) = \psi(x) = \psi(f(x)) = fh^{-1}(x)$ which implies that $h^{-1}$ normalises $\text{Stab}_G(x)$. Now (5.2) shows that $\psi = F([h])$, where $[h]$ is the class of $h$ in $N_G(\text{Stab}_G(x)) / \text{Stab}_G(x)$. □

Let $G_1$ and $G_2$ be two groups acting on $X_1$ and $X_2$, respectively. Let $G \subset G_1 \times G_2$ be a subgroup such that the projection $p_1 : G \rightarrow G_1$ is surjective. $G_1 \times G_2$ acts on $X_1$ via the projection $p_1$ and hence $G$ also acts on $X_1$; if $f \in G$, then $f(x) := f_1(x)$, where $f_1 = p_1(f)$.

**Lemma 5.3.** In the above context, let $x \in X_1$. Then $p_1$ induces an isomorphism

$$N_G(\text{Stab}_G(x)) / \text{Stab}_G(x) \rightarrow N_{G_1}(\text{Stab}_{G_1}(x)) / \text{Stab}_{G_1}(x).$$
Lemma 5.2 to the space \( e.X/ \).

Definition 5.4. Let \( f \in G \) belongs to \( \text{Stab}_G(x) \) iff \( f_1(x) = x \). Hence \( p_1^{-1}(\text{Stab}_{G_1}(x)) = \text{Stab}_G(x) \). In particular, \( p_1 \) descends to the quotients. \( h \in G \) belongs to \( N_G(\text{Stab}_G(x)) \) iff \( f h^{-1}(x) = h^{-1}(x) \) for all \( f \in \text{Stab}_G(x) \). Since \( p_1^{-1}(\text{Stab}_{G_1}(x)) = \text{Stab}_G(x) \), we have that the latter is equivalent to \( f_1 h_1^{-1}(x) = h_1^{-1}(x) \) for all \( f_1 \in \text{Stab}_{G_1}(x) \). Hence \( N_{G_1}(\text{Stab}_{G_1}(x)) = p_1(N_G(\text{Stab}_G(x))) \). Hence the map induced by \( p_1 \) is surjective. \( p_1^{-1}(\text{Stab}_{G_1}(x)) = \text{Stab}_G(x) \) shows that \( p_1(h) \in \text{Stab}_{G_1}(x) \) implies \( h \in \text{Stab}_G(x) \) and so the map induced by \( p_1 \) is injective.

5.2.1. Definition of the virtual automorphism group. Let \((X, \sigma, T)\) be a minimal system with abelian group \( T \). We denote its Ellis semigroup here simply by \( E \). Let \( e \in E \) be a minimal idempotent and recall that \( \mathcal{E} = e E e \) is a group. Pick \( x_0 \in e(X) \). Applying Lemma 5.2 to the space \( e(X) \) and the group \( G = \mathcal{E} \), we get

\[
N_{\mathcal{E}}(\text{Stab}_{\mathcal{E}}(x_0)) / (\text{Stab}_{\mathcal{E}}(x_0)) \cong C_{S_{e(X)}}(\mathcal{E}).
\]

Definition 5.4. Let \((X, \sigma, T)\) be minimal and let \( e \in E \) be a minimal idempotent in its Ellis semigroup. The virtual automorphism group \( V(X) \) of \((X, \sigma)\) is defined to be \( C_{S_{e(X)}}(\mathcal{E}) \).

While this definition depends on the choice of the minimal idempotent \( e \), it does so only up to isomorphism, as different choices of idempotents lead to isomorphic groups.

We remark that the restriction map

\[
\text{Aut}(X) \ni \Phi \mapsto \Phi|_{e(X)} \in C_{S_{e(X)}}(\mathcal{E})
\]

is well defined, as automorphisms commute with the elements of \( E(X) \). Furthermore, if \( e(X) \) is dense in \( X \), then this restriction map is an injective group homomorphism, as automorphisms are continuous. A condition guaranteeing that \( e(X) \) is dense in \( X \) is point distality of \((X, \sigma, T)\), as minimal idempotents fix distal points. So for a point distal minimal system \((X, \sigma, T)\), \( \text{Aut}(X) \) is a subgroup of \( V(X) \).

Definition 5.5. The minimal dynamical system \((X, \sigma, T)\) is called semi-regular if the restriction map \( \Phi \mapsto \Phi|_{e(X)} \) is an isomorphism between the automorphism group \( \text{Aut}(X) \) and the virtual automorphism group \( V(X) \).

Note that our definition is slightly different to Auslander and Glasner’s, who simply require that the map \( \text{Aut}(X) \to V(X) \) be onto. However, for point distal systems, and the systems we study here are point distal, the definitions coincide.

5.2.2. Unique singular fibre systems. We investigate the virtual automorphism group \( V(X) \) for minimal systems which have an equicontinuous factor with a unique orbit of singular points. Recall the definition (3.2) of \( \mathcal{T} \) as the subsemigroup of elements of \( E_{\text{fib}} \) which act trivially on regular fibres and that its restriction \( \mathcal{T}_{\gamma_0} \) to \( \pi^{-1}(\gamma_0) \) is faithful. Recall the notation \( \mathcal{E} = e E_{\text{fib}} e \).

Lemma 5.6. Let \((X, \sigma, T)\) be a minimal unique singular orbit system. Let \( \gamma_0 \) be a singular point in its maximal equicontinuous factor and \( x_0 \in e \pi^{-1}(\gamma_0) \). If \( e \mathcal{T}_{\gamma_0} e \) acts effectively\(^3\)

\(^3\)For any \( x \in e \pi^{-1}(\gamma_0) \) there exists \( \gamma \in e \mathcal{T}_{\gamma_0} e \) such that \( \gamma(x) \neq x \).
on \( e \pi^{-1}(y_0) \), then

\[
N_G(\Stab_G(x_0)) = N_{G^{\fib}}(\Stab_{G^{\fib}}(x_0)) \times T.
\]

**Proof.** By Theorem 3.6 \( G^{\fib} \) contains \( \Cov_T \) as defined in (3.3) and therefore

\[
\Stab_G(x_0) \supset \{ \tilde{f} \in \Cov_{Te} : \tilde{f}(y_0)(x_0) = x_0 \}. \tag{5.3}
\]

Let \( h \in N_G(\Stab_G(x_0)) \). Then \( f(h(x_0)) = h(x_0) \) for all \( f \in \Stab_G(x_0) \). Using \( y := \tilde{\pi}(h) + y_0 \) this means that \( \tilde{f}(y)(h(x_0)) = h(x_0) \). Suppose that \( y - y_0 \notin T \subset Y \) (\( T \) seen as a subgroup of the maximal equicontinuous factor \( Y \)). Since \( eT_{y_0}e \) acts effectively, there is \( \gamma \in eT_{y_0}e \) such that \( \Phi_{y_0}^T(\gamma)(h(x_0)) \neq h(x_0) \). By (5.3) there exists \( f \in \Stab_G(x_0) \) such that \( \tilde{f}(y) = \Phi_{y_0}^T(\gamma) \). For this element we have \( f(h(x_0)) = \Phi_{y_0}^T(\gamma)(h(x_0)) \neq h(x_0) \). This is a contradiction and thus all \( h \in N_G(\Stab_G(x_0)) \) must satisfy \( \tilde{\pi}(h) \in T \). Clearly, \( \sigma \in N_G(\Stab_G(x_0)) \) and so the above shows that the exact sequence \( G^{\fib} \hookrightarrow G \twoheadrightarrow Y \) restricts to the exact sequence

\[
N_{G^{\fib}}(\Stab_{G^{\fib}}(x_0)) \hookrightarrow N_G(\Stab_G(x_0)) \twoheadrightarrow T.
\]

We can lift the subgroup \( T \subseteq Y \) with the lift \( s : T \to E \) given by \( s(t) = \sigma^t \) to see that \( N_G(\Stab_G(x_0)) \) is a semidirect product, which is in fact direct, as \( \sigma^t \) commutes with \( E \), since \( T \) is abelian.

**Lemma 5.7.** Let \((X, \sigma, T)\) be a minimal system with equicontinuous factor \( \pi : X \to Y \). Let \( y_0 \in Y \), \( x_0 \in e \pi^{-1}(y_0) \), where \( e \) is a minimal idempotent of \( E(X) \). One has

\[
N_{G^{\fib}}(\Stab_{G^{\fib}}(x_0)) \cong C_{S_{e \pi^{-1}(y_0)}(G_\pi)}.
\]

**Proof.** \( G^{\fib} \) is a subgroup of \( e \Cove e = \prod_{y \in Y_0} eE^{\fib}_xe \), where \( Y_0 \subseteq Y \) contains exactly one representative for each orbit and we suppose that \( y_0 \in Y_0 \). Thus \( e \Cove e \) has the form \( G_1 \times G_2 \) with \( G_1 = G_\pi = eE^{\fib}_{y_0}e \) and the projection \( p_1 \) is surjective. We thus can apply Lemma 5.3 and then Lemma 5.2 to see that

\[
N_{G^{\fib}}(\Stab_{G^{\fib}}(x_0)) \cong N_{eE^{\fib}_{y_0}e}(\Stab_{eE^{\fib}_{y_0}e}(x_0)) \cong C_{S_{e \pi^{-1}(y_0)}(G_\pi)}.
\]

**Corollary 5.8.** Let \((X, \sigma)\) be a minimal unique singular orbit system. Let \( y_0 \) be a singular point of its maximal equicontinuous factor. If \( eT_{y_0}e \) acts effectively, then the virtual automorphism group is given by

\[
V(X) \cong C_{S_{e \pi^{-1}(y_0)}(G_\pi)} \times T.
\]

**Proof.** Combine Lemmas 5.6 and 5.7.

We provide a criterion for effectiveness of the action of \( eT_{y_0}e \).

**Lemma 5.9.** Let \( X \) be a set and let \( \Gamma \) be a non-trivial normal subgroup of a subgroup \( G \subseteq S_X \) which acts transitively on \( X \). Then \( \Gamma \) acts effectively on \( X \).
Proof. Let \( F_\Gamma = \{ a \in X : \Gamma(a) = \{ a \} \} \). If \( h \in N_{S_X}(\Gamma) \), then for \( a \in F_\Gamma \)

\[
\Gamma h(a) = \{ \gamma h(a) : \gamma \in \Gamma \} = \{ h\gamma'(a) : \gamma' \in \Gamma \} = \{ h(a) \},
\]
so that \( h(a) \in F_\Gamma \). By assumption, \( G \) lies in \( N_{S_X}(\Gamma) \), so that \( G(F_\Gamma) \subseteq F_\Gamma \). Since \( G \) is transitive, we have either \( F_\Gamma = X \) or \( F_\Gamma = \emptyset \). In the first case, \( \Gamma \) can consist only of the identity, and in the second \( \Gamma \) acts effectively.

We thus see that \( eT_{\vartheta_0}e \) acts effectively if it is non-trivial and \( eE_{\vartheta_0}^{\text{fib}}e \) acts transitively on \( e\varpi^{-1}(\vartheta_0) \).

5.2.3. Bijective substitutions. We now focus again on the dynamical systems of primitive aperiodic bijective substitutions. Recall that in this case we can identify \( e \) with the alphabet \( \mathcal{A} \) using the map \( ev_0 \). Under this isomorphism, \( G_{\varpi} = eE_{\vartheta_0}^{\text{fib}}e \cong G_{\vartheta} \) and \( eT_{\vartheta_0}e \cong \bar{\Gamma}_{\vartheta} \). Since \( \theta \) is assumed primitive, the structure group \( G_{\vartheta} \) must act transitively on \( \mathcal{A} \). Aperiodicity of the substitution implies that \( I_{\vartheta} \) must consist of at least 2 elements. Hence \( \Gamma_{\vartheta} \) is non-trivial, so, by Lemma 5.9, \( \bar{\Gamma}_{\vartheta} \) acts effectively on \( \mathcal{A} \).

Corollary 5.10. Let \( \vartheta \) be a primitive aperiodic bijective substitution. The virtual automorphism group is given by

\[
V(X_{\vartheta}) \cong C_{S_{\mathcal{A}}}(G_{\vartheta}) \times \mathbb{Z}.
\]

Proof. All hypotheses of Corollary 5.8 are satisfied.

Corollary 5.11. The dynamical system of a primitive aperiodic bijective substitution is semi-regular.

Proof. We see from Theorems 5.1 and Corollary 5.10 that the virtual automorphism group is isomorphic to the automorphism group. Furthermore, their fibre preserving parts are isomorphic. Since these are finite groups and the automorphism group is included in the virtual automorphism group, the map from Definition 5.5 must be an isomorphism.

Since the virtual automorphism group \( V(X_{\vartheta}) \) can be expressed by means of the Ellis semigroup \( E(X_{\vartheta}) \), as we saw above, Corollary 5.11 describes the relation between \( E(X_{\vartheta}) \) and \( \text{Aut}(X_{\vartheta}) \). Note that no non-trivial element of \( \text{Aut}_{\text{fib}}(X_{\vartheta}) \) can be an element of \( E_{\text{fib}}(X_{\vartheta}) \) as \( E_{\text{fib}}(X_{\vartheta}) \setminus \{ \text{Id} \} \) is a proper ideal and therefore cannot contain an invertible element.

6. Examples

We provide here a list of examples of Ellis semigroups of dynamical systems defined by a primitive, aperiodic, bijective substitution \( \vartheta \) of constant length \( \ell \) over a finite alphabet \( \mathcal{A} \). For the benefit of the reader, we summarise results and recall calculation of \( E(X_{\vartheta}) \).

\( E(X_{\vartheta}) \) is the disjoint union of its kernel \( \mathcal{M}(X_{\vartheta}) \) with the acting group \( \mathbb{Z} \). It depends only on the \( \mathcal{R} \)-set \( I_{\vartheta} \subset S_{\mathcal{A}} \), which can easily be computed as in Lemma 4.5. But to
J. Kellendonk and R. Yassawi

describe its associated Rees matrix form we make a choice of minimal idempotent \( e \in E(X_\theta, \mathbb{Z}^+) \) which amounts to a choice of element \( g_0 \in I_\theta \). Different choices for \( e \) lead to isomorphic expressions, and, as far as the fibre preserving parts are concerned, even homeomorphic ones.

The first result is that the structural semigroup \( \mathcal{M}^0_\text{fib}(X_\theta) \) is isomorphic to the normalised matrix semigroup

\[
\mathcal{M}^0_\text{fib}(X_\theta) \cong M\left[G_\theta; I_\theta, \{\pm\}; A\right],
\]

where the structure group \( G_\theta \) is the group generated by \( I_\theta \), the + entries of \( A \) equal 1, and the − entries of \( A \) equal \( g_0^{-1}g \), \( g \in I_\theta \). They generate a subgroup of \( G_\theta \) which we call the little structure group \( \mathcal{E}_\theta \). Everything is finite at this level and so topologically trivial.

Next, the fibre preserving part \( \mathcal{M}^\text{fib}(X_\theta) \) is topologically isomorphic to the normalised matrix semigroup

\[
\mathcal{M}^\text{fib}(X_\theta) \cong M\left[\mathcal{G}^\text{fib}_\theta, I_\theta, \{\pm\}; A\right],
\]

where \( I_\theta \) is the same as above. The quotient \( G_\theta/\Gamma_\theta \) of \( G_\theta \) by the normal completion \( \Gamma_\theta \) of the little structure group must be a cyclic group, its order \( h \) is the generalised height of the substitution. The structure group of \( \mathcal{M}^\text{fib}(X_\theta) \) is \( \mathbb{Z}/h\mathbb{Z} \)-graded and its subgroup of elements of degree 0 is

\[
\mathcal{G}^\text{fib}_\theta 0 \cong \overline{\mathbb{Z}_\ell}/\mathbb{Z}.
\]

If \( G_\theta \) contains an element of order \( h \), then

\[
\mathcal{G}^\text{fib}_\theta \cong \overline{\mathbb{Z}_\ell}/\mathbb{Z} \rtimes \mathbb{Z}/h\mathbb{Z},
\]

a semidirect product whose explicit expression depends on the choice of an element \( \mathring{\theta} \) of \( \mathcal{G}^\text{fib}_\theta \) of degree 1. The sandwich matrix \( A \) is the same as that for \( \mathcal{M}^0_\text{fib}(X_\theta) \), because we view \( \Gamma_\theta \) as a subgroup of \( \overline{\mathbb{Z}_\ell}/\mathbb{Z} \): an element \( g \in \Gamma_\theta \) maps to the function of \( \overline{\mathbb{Z}_\ell}/\mathbb{Z} \) which takes value \( g \) on \([0]\) and \(1\) otherwise. If generalised height is trivial, then we can rewrite the above

\[
\mathcal{M}^\text{fib}(X_\theta) \cong \mathcal{M}^0_\text{fib}(X_\theta) \times \prod_{[z] \in \mathbb{Z}_\ell/\mathbb{Z}, [z] \neq [0]} G_\theta
\]

again a topological isomorphism.

Finally, the kernel \( \mathcal{M}(X_\theta) \) of the full Ellis semigroup has Rees-matrix form

\[
\mathcal{M}(X_\theta) \cong M\left[\mathcal{G}_\theta; I_\theta, \{\pm\}; A\right],
\]

where \( \mathcal{G}_\theta \) is an extension of the equicontinuous factor \( \mathbb{Z}_\ell \) by \( \mathcal{G}^\text{fib}_\theta \). This isomorphism is only algebraic. Again \( I_\theta \) and the sandwich matrix \( A \) are the same, as \( \mathcal{G}^\text{fib}_\theta \) is a subgroup of \( \mathcal{G}_\theta \). The extension is algebraically split if the height is equal to the classical height \( h = h_{\text{cl}} \) of the substitution. In this case,

\[
\mathcal{G}_\theta \cong \mathcal{G}^\text{fib}_\theta \rtimes \mathbb{Z}_\ell,
\]

algebraically.

Besides the details for the Ellis semigroup, we provide below also \( C_{S_A}(G_\theta) \), the centraliser of \( G_\theta \) in the group of permutations of the alphabet, which is also \( \text{Aut}^{\text{fib}}(X_\theta) \).
For the arbitrary size of the alphabet, we can say the following. There is no aperiodic bijective substitution with $|I_\theta| = 1$. If $I_\theta$ contains two elements, then $\Gamma_\theta$ must be a cyclic subgroup of $G_\theta$.

6.1. Two-letter alphabet

To be compatible with primitivity and aperiodicity, we must have $I_\theta = S_2$. Hence $G_\theta = S_2 = \mathbb{Z}/2\mathbb{Z}$ and $\Gamma_\theta = \bar{\Gamma}_\theta = S_2$. Thus all primitive, aperiodic, bijective substitutions on a two-letter alphabet have the same structural semigroup, namely $M[S_2; S_2, \{\pm\}; A]$. The sandwich matrix is $A = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}$, where $\omega$ interchanges $a$ with $b$. The generalised height is trivial for these substitutions. We thus have

$$G_{\text{fib}}^\theta \cong S_2^{\mathbb{Z}_\ell/\mathbb{Z}} \quad \text{and} \quad \mathcal{G}_\theta \cong S_2^{\mathbb{Z}_\ell/\mathbb{Z}} \rtimes \mathbb{Z}_\ell,$$

where $\ell$ is the length of the substitution.

$M[S_2; S_2, \{\pm\}; A]$ is perhaps the simplest non-orthodox semigroup. Since $S_2$ is abelian, we have $C_{S_A}(G_\theta) = G_\theta$. Thus all these substitutions have $\text{Aut}^\text{fib}(X_\theta) = S_2$, generated by the map $\omega$. The simplest example of this type is the (simplified) Thue–Morse substitution, $\theta(a) = abba, \theta(b) = baab$, where the above result has been obtained by Marcy Barge in a direct calculation [6].

6.2. Three-letter alphabet

If $G_\theta$ is a subgroup of $S_2 \subset S_3$, then we reproduce the above results for the semigroup, but these can never be realised by a primitive substitution on three letters, as one letter would stay fixed. So we consider the two possible other cases, $G_\theta = S_3$ and $G_\theta = A_3 \cong \mathbb{Z}/3\mathbb{Z}$. For $G_\theta = S_3$, we give below examples where $\Gamma_\theta \cong \mathbb{Z}/2\mathbb{Z}$ or $\Gamma_\theta \cong \mathbb{Z}/3\mathbb{Z}$. In the first case, $\Gamma_\theta \cong \mathbb{Z}/2\mathbb{Z}$ has normal completion $G_\theta$ and so the height is trivial. In the second case $\Gamma_\theta \cong \mathbb{Z}/3\mathbb{Z}$ is normal in $G_\theta$ and the height is equal to 2. The example we provide for this case has classical height 1. We also give an example where $G_\theta \cong \mathbb{Z}/3\mathbb{Z}$, which, for aperiodic $\theta$, forces $\Gamma_\theta \cong \mathbb{Z}/3\mathbb{Z}$ so that we have again trivial height.

(1) Consider the substitution $\theta$

$$a \rightarrow abc\,ca$$
$$b \mapsto bab\,abc$$
$$c \mapsto cc\,abc$$

Then it can be verified that $I_\theta = \left\{ \begin{pmatrix} b \\ c \\ a \end{pmatrix}, \begin{pmatrix} b \\ c \\ a \end{pmatrix} \right\}$ which generates $G_\theta = S_3$. The structural semigroup is $M[S_3; I_\theta, \{\pm\}; A]$, whose normalised sandwich matrix is $A = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}$, where $\omega$ exchanges $b$ with $c$. One finds $\Gamma_\theta = \left\{ 1, \begin{pmatrix} b \\ a \end{pmatrix} \right\} \cong \mathbb{Z}/2\mathbb{Z}$, which is not normal in $S_3$, and $\bar{\Gamma}_\theta = G_\theta = S_3$. Thus $\theta$ has trivial generalised height. Hence

$$G_{\text{fib}}^\theta \cong S_3^{\mathbb{Z}_5/\mathbb{Z}} \quad \text{and} \quad \mathcal{G}_\theta \cong S_3^{\mathbb{Z}_5/\mathbb{Z}} \rtimes \mathbb{Z}_5.$$ 

Also $C_{S_A}(G_\theta) = \text{Aut}^\text{fib}(X_\theta)$ is trivial.
(2) Consider the substitution $\theta$

\[
\begin{align*}
 a & \mapsto abacaaa \\
 b & \mapsto babbbcb \\
 c & \mapsto cccacbc
\end{align*}
\]

It has $\theta_0 = \theta_2 = \theta_4 = \theta_6 = 1$ and the other three are the transpositions of $S_3$, $\theta_1 = \begin{pmatrix} b \\ a \\ c \end{pmatrix}$, $\theta_3 = \begin{pmatrix} b \\ a \\ c \end{pmatrix}$, and $\theta_5 = \begin{pmatrix} c \\ a \\ b \end{pmatrix}$. Hence $I_\theta = \{ \theta_1, \theta_3, \theta_5 \}$ and $G_\theta = S_3$. The structural semigroup is $M[S_3; I_\theta, \{ \pm \}; A]$ and has a normalised sandwich matrix $\begin{pmatrix} 1 & 1 & 1 \\ 1 & \omega & \omega^2 \end{pmatrix}$, where $\omega = \begin{pmatrix} b \\ c \\ a \end{pmatrix}$, a cyclic permutation.

Every element in $\Gamma_\theta$ is an even permutation, thus $\Gamma_\theta = \Gamma_\theta = A_3$. It follows that $G_\theta / \Gamma_\theta \cong \mathbb{Z}/2\mathbb{Z}$ and $\theta$ has generalised height equal to 2 and therefore

\[
\mathcal{G}_\theta^{\text{fib}} \cong A_3^{\mathbb{Z}_3 / \mathbb{Z}}, \quad \mathcal{G}_\theta^{\text{fib}} \cong A_3^{\mathbb{Z}_3 / \mathbb{Z} \times \mathbb{Z} / 2\mathbb{Z}},
\]
as $\theta_1 \in I_\theta$ has order 2.

Note that the substitution has trivial classical height as any fixed point must contain the word $aa$. We do therefore not know whether the extension $A_3^{\mathbb{Z}_3 / \mathbb{Z} \times \mathbb{Z} / 2\mathbb{Z}} \hookrightarrow \mathcal{G}_\theta \xrightarrow{\pi} \mathbb{Z}_3$ defining the structure group $\mathcal{G}_\theta$ of $M(X_\theta)$ splits. Again, $C_{S_A}(G_\theta) = \text{Aut}^{\text{fib}}(X_\theta)$ is trivial.

This example has a natural generalisation to alphabets of any size $s$ with $G_\theta = S_s$ and $\Gamma_\theta = A_s$, the alternating group on $s$ elements.

(3) Consider the substitution $\theta$

\[
\begin{align*}
 a & \mapsto abc \\
 b & \mapsto bca \\
 c & \mapsto cab
\end{align*}
\]

whose third power is simplified. We find $I_\theta = \{ 1, \omega, \omega^2 \} \cong \mathbb{Z}/3\mathbb{Z}$, where $\omega = \begin{pmatrix} b \\ c \\ a \end{pmatrix}$ is a cyclic permutation. It follows that $G_\theta = \Gamma_\theta = \Gamma_\theta \cong \mathbb{Z}/3\mathbb{Z}$. The structural semigroup is $M[\mathbb{Z}/3\mathbb{Z}; I_\theta, \{ \pm \}; A]$, where $A = \begin{pmatrix} 1 & 1 & 1 \\ 1 & \omega & \omega^2 \end{pmatrix}$,

\[
\mathcal{G}_\theta^{\text{fib}} \cong (\mathbb{Z}/3\mathbb{Z})^{\mathbb{Z}_3 / \mathbb{Z}} \quad \text{and} \quad \mathcal{G}_\theta^{\text{fib}} \cong (\mathbb{Z}/3\mathbb{Z})^{\mathbb{Z}_3 / \mathbb{Z} \times \mathbb{Z}_3}.
\]

Finally, $C_{S_A}(G_\theta) = \text{Aut}^{\text{fib}}(X_\theta) \cong \mathbb{Z}/3\mathbb{Z}$, generated by $\omega$. There is an obvious generalisation of this example to alphabets of any size $s \geq 2$, the case $s = 2$ corresponding again to the Thue–Morse substitution.

### 6.3. Four-letter alphabet

Our last example is related to the dihedral group $D_4$. Consider the substitution $\theta$ of length 7

\[
\begin{align*}
 a & \mapsto abadcba \\
 b & \mapsto babcabb \\
 c & \mapsto cdcabdc \\
 d & \mapsto dcdbadcd
\end{align*}
\]
which has classical height 2. If we identify the letters with the edges of a square whose center is 0 in such a way that $a$ corresponds to the lower right corner and we order the edges counterclockwise, then $\theta_1$ and $\theta_3$ amount to the reflection along the $x$-axis and the $y$-axis, respectively, while $\theta_2$ and $\theta_4$ amount to the reflection along the diagonal with slope $-1$ and $+1$, respectively. Finally, $\theta_5 = \theta_1$ and $\theta_6 = \theta_0 = 1$. Thus $I_\theta = \{\theta_1, \rho\}$, where $\rho = \theta_1 \theta_2$ is the rotation by $\frac{\pi}{2}$ to the right. It follows that $G_\theta = D_4$ is the dihedral group of order 4 and that $\Gamma_\theta$ the group of order 2 generated by the reflection $\theta_2$. Its normal completion is thus the group generated by the reflections $\theta_2$ and $\theta_4$, which commute, so $\bar{\Gamma}_\theta \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ showing that height is equal to the classical height, namely 2. Moreover, the element $\theta_1$ of $I_\theta$ has order 2. The structural semigroup is $\mathcal{M}_{\text{fib}}(X_\theta) = M[D_4; I_\theta, \{\pm\}; A]$ with $A = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 4 \end{smallmatrix}\right)$. Furthermore,

$$\Theta^\text{fib}_\theta \cong (\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z})^{\mathbb{Z}_7/\mathbb{Z}} \rtimes \mathbb{Z}/2\mathbb{Z},$$

$$\Theta_\theta \cong (\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z})^{\mathbb{Z}_7/\mathbb{Z}} \rtimes \mathbb{Z}/2\mathbb{Z} \rtimes \mathbb{Z}_7.$$ 

Finally, $C_{S_A}(G_\theta) = \text{Aut}^\text{fib}(X_\theta) = \{1, \rho^2\}$.

**Acknowledgements.** The authors are very grateful to the referee, whose numerous suggestions and questions led not only to an improvement in the exposition, but also to an extension of the results, namely the recovering of the full Ellis semigroup from its fibre preserving part in Corollary 3.14, and Theorems 4.12 and 4.22. J. Kellendonk would like to thank Marcy Barge for discussions about the Ellis semigroup of substitutional systems. Both authors thank Eli Glasner and Olivier Mathieu for their useful comments.

**Funding.** This project has received funding from the European Research Council (ERC) under the European Union’s Horizon 2020 research and innovation programme under the Grant Agreement No 648132.
