ABSTRACT

By formulating $\mathcal{N} = 1, 2, 4, 8$, $D = 3$, Yang-Mills with a single Lagrangian and single set of transformation rules, but with fields valued respectively in $\mathbb{R}, \mathbb{C}, \mathbb{H}, \mathbb{O}$, it was recently shown that tensoring left and right multiplets yields a Freudenthal-Rosenfeld-Tits magic square of $D = 3$ supergravities. This was subsequently tied in with the more familiar $\mathbb{R}, \mathbb{C}, \mathbb{H}, \mathbb{O}$ description of spacetime to give a unified division-algebraic description of extended super Yang-Mills in $D = 3, 4, 6, 10$. Here, these constructions are brought together resulting in a magic pyramid of supergravities. The base of the pyramid in $D = 3$ is the known $4 \times 4$ magic square, while the higher levels are comprised of a $3 \times 3$ square in $D = 4$, a $2 \times 2$ square in $D = 6$ and Type II supergravity at the apex in $D = 10$. The corresponding U-duality groups are given by a new algebraic structure, the magic pyramid formula, which may be regarded as being defined over three division algebras, one for spacetime and each of the left/right Yang-Mills multiplets. We also construct a conformal magic pyramid by tensoring conformal supermultiplets in $D = 3, 4, 6$. The missing entry in $D = 10$ is suggestive of an exotic theory with $G/H$ duality structure $F_4(4)/\text{Sp}(3) \times \text{Sp}(1)$. 
1 Introduction

In recent years gauge and gravitational scattering amplitudes have undergone something of a renaissance [1], resulting not only in dramatic computational advances but also important conceptual insights. One such development, straddling both the technical and conceptual, is the colour-kinematic duality of gauge amplitudes introduced by Bern, Carrasco and Johansson [2]. Exploiting this duality it has been shown that gravitational amplitudes may be reconstructed using a double-copy of gauge amplitudes suggesting a possible interpretation of perturbative gravity as “the square of Yang-Mills” [3, 4]. This perspective has proven itself remarkably effective, rendering possible previously intractable gravitational scattering amplitude calculations [5]; it is both conceptually suggestive and technically advantageous. Yet, the idea of gravity as the square of Yang-Mills is not specific to amplitudes, having appeared previously in a number of different, but sometimes related, contexts [6–10].

While it would seem there is now a growing web of relations connecting gravity to “gauge × gauge”, it is as yet not clear to what extent gravity may be regarded as the square of Yang-Mills. Here, we ask how the non-compact global symmetries of supergravity [11], or in an M-theory context the so-called U-dualities [12,13], might be related to the “square” of those in super Yang-Mills (SYM), namely R-symmetries. Surprisingly, in the course of addressing this question the division algebras \( A = R, C, H, O \) and their associated symmetries reveal themselves as playing an intriguing role. Tensoring, as in \([14, N_L, N_R] \) super Yang-Mills multiplets in \( D = 3, 4, 6, 10 \) dimensions yields supergravities with U-dualities given by a magic pyramid formula parametrized by a triple of division algebras \( (A_{nL}, A_{nN_L}, A_{nN_R}) \), one for spacetime and two for the left/right Yang-Mills multiplets. While it would seem there is now a growing web of relations connecting gravity to “gauge × gauge”, it is as yet not clear to what extent gravity may be regarded as the square of Yang-Mills.

Here, we ask how the non-compact global symmetries of supergravity [11], or in an M-theory context the so-called U-dualities [12,13], might be related to the “square” of those in super Yang-Mills (SYM), namely R-symmetries. Surprisingly, in the course of addressing this question the division algebras \( A = R, C, H, O \) and their associated symmetries reveal themselves as playing an intriguing role. Tensoring, as in \([14, N_L, N_R] \) super Yang-Mills multiplets in \( D = 3, 4, 6, 10 \) dimensions yields supergravities with U-dualities given by a magic pyramid formula parametrized by a triple of division algebras \( (A_{nL}, A_{nN_L}, A_{nN_R}) \), one for spacetime and two for the left/right Yang-Mills multiplets. While it would seem there is now a growing web of relations connecting gravity to “gauge × gauge”, it is as yet not clear to what extent gravity may be regarded as the square of Yang-Mills.

In previous work [15] we built a symmetric \( 4 \times 4 \) array of three-dimensional supergravity multiplets, with \( N = N_L + N_R \), by tensoring a left \( N_L = 1, 2, 4, 8 \) SYM multiplet with a right \( N_R = 1, 2, 4, 8 \) SYM multiplet. Remarkably, the corresponding U-dualities filled out the Freudenthal-Rosenfeld-Tits magic square [16,21]; a symmetric \( 4 \times 4 \) array of Lie algebras defined by a single formula taking as its argument a pair of division algebras,

\[
\mathcal{L}_d(A_{N_L}, A_{N_R}) := \text{tri}(A_{N_L}) \oplus \text{tri}(A_{N_R}) + 3(A_{N_L} \otimes A_{N_R}),
\]

where the subscripts denote the dimension of the algebras. See Table 1. Here, \( \text{tri}(A) \) denotes the triality Lie algebra of \( A \), a generalisation of the algebra of derivations which contains as a sub-algebra the R-symmetry of super Yang-Mills. See section 2.
Here is the text:

| $\mathbb{A}_L/\mathbb{A}_R$ | $\mathbb{R}$ | $\mathbb{C}$ | $\mathbb{H}$ | $\mathbb{O}$ |
|--------------------------|-------------|-------------|-------------|-------------|
| $\mathbb{R}$             | SL(2, $\mathbb{R}$) | SU(2, 1)    | USp(4, 2)   | $F_4(-20)$  |
| $\mathbb{C}$             | SU(2, 1)    | SU(2, 1) × SU(2, 1) | SU(4, 2)    | $E_6(-14)$  |
| $\mathbb{H}$             | USp(4, 2)   | SU(4, 2)    | SO(8, 4)    | $E_7(-5)$   |
| $\mathbb{O}$             | $F_4(-20)$  | $E_6(-14)$  | $E_7(-5)$   | $E_8(8)$    |

Table 1: The magic square

The Freudenthal-Rosenfeld-Tits magic square\(^1\) historically originated from efforts to understand the exceptional Lie groups in terms of octonionic geometries and, accordingly, the scalar fields of the corresponding supergravities parametrize division algebraic projective spaces [15]. The connection to the division algebras in fact goes deeper; the appearance of the magic square can be explained using the observation that the $D = 3$, $\mathcal{N} = 1, 2, 4, 8$ Yang-Mills theories can be formulated with a single Lagrangian and a single set of transformation rules, using fields valued in $\mathbb{R}$, $\mathbb{C}$, $\mathbb{H}$ and $\mathbb{O}$, respectively. Tensoring an $\mathbb{A}_{N_L}$-valued super Yang-Mills multiplet with an $\mathbb{A}_{N_R}$-valued super Yang-Mills multiplet yields a supergravity multiplet with fields valued in $\mathbb{A}_{N_L} \otimes \mathbb{A}_{N_R}$, making a magic square of U-dualities appear rather natural.

Of course, the connection between supersymmetry and division algebras is not new. In particular, Kugo and Townsend [26] related the existence of minimal $\mathcal{N} = 1$ super Yang-Mills multiplets in only three, four, six and ten dimensions directly to the existence of only four division algebras $\mathbb{R}$, $\mathbb{C}$, $\mathbb{H}$ and $\mathbb{O}$, an observation which has been subsequently developed in a variety of directions. See, for example, [27–41] and the references therein. From this point of view the division algebras are related to the spacetime symmetries, rather than the internal R-symmetries, via the Lie algebra isomorphism (in the sense of [27])

$$\mathfrak{so}(2, \mathbb{A}_n) \cong \mathfrak{so}(1, n + 2). \quad (1.2)$$

Indeed, the unique $D = 10$, $\mathcal{N} = 1$ super Yang-Mills theory can be formulated using octonionic spacetime fields [39]. By dimensionally reducing this octonionic theory, which corresponds to Cayley-Dickson halving, one recovers the octonionic formulation of $D = 3$, $\mathcal{N} = 8$ Yang-Mills presented in [15], tying together the division algebraic descriptions of spacetime and supersymmetry. This approach gives a unified division algebraic description of $(D = 3, \mathcal{N} = 1, 2, 4, 8)$, $(D = 4, \mathcal{N} = 1, 2, 4)$, $(D = 6, \mathcal{N} = 1, 2)$ and $(D = 10, \mathcal{N} = 1)$ Yang-Mills theories. A given $(D = n + 2, \mathcal{N})$ theory (the field content, Lagrangian and transformation rules) is completely specified by selecting an ordered pair $\mathbb{A}_n \subseteq \mathbb{A}_{n', n''}$, where again the subscripts denote the dimension of the algebras [41]. This unity is neatly expressed through the fact that the (modified) triality algebras appearing in [11] are the direct sum of the spacetime little group and the internal R-symmetry algebras [41].

In the present work we bring together the various roles of the division algebras discussed above to construct a pyramid of supergravities by tensoring left/right $\mathbb{A}_{nN_L}/\mathbb{A}_{nN_R}$-valued Yang-Mills multiplets in $D = n + 2$. The base of the pyramid in $D = 3$ is the $4 \times 4$ magic square of supergravities, with a $3 \times 3$ square in $D = 4$, a $2 \times 2$ square in $D = 6$ and Type II supergravity at the apex in $D = 10$. The totality defines a new algebraic structure: the magic pyramid. The U-dualities are given by the magic pyramid formula,

$$\Psi\mu(\mathbb{A}_n, \mathbb{A}_{nN_L}, \mathbb{A}_{nN_R}) := \left\{ u \in \mathcal{L}_3(\mathbb{A}_{nN_L}, \mathbb{A}_{nN_R}) \mid \mathfrak{so}(\mathbb{A}_n)_{ST} [u, \mathfrak{so}(\mathbb{A}_n)_{ST}] = 0 \right\}, \quad (1.3)$$

---

\(^1\)There are a number of equivalent forms/constructions of the magic square formula [11] due to, amongst others, Tits [20], Vinberg [21], Kantor [22] and Barton-Sudbery [23]. The ternary algebra approach of [22] was generalised by Bars-Günaydin [24] to include super Lie algebras. The form given in [11] is due to Barton-Sudbery. We adopt this construction, modified as a Lie algebra to produce the required real forms presented in Table 1, as will be explained in section 2. This specific square of real forms was first derived in [25] using Tits’ formula defined over a Lorentzian Jordan algebra. By, for example, altering the signature of the algebras a variety of real forms can be accommodated. See [25] for a comprehensive account in the context of supergravity.
Figure 1: A magic pyramid of supergravities. The vertical axis labels the spacetime division algebra $A_n$, while the horizontal axes label the algebras associated with the number of supersymmetries $A_nN_L$ and $A_nN_R$.

where $\mathfrak{so}(A_n)_{ST} \subset \mathfrak{so}(A_nN_L, A_nN_R)$ is the subalgebra of on-shell spacetime transformations (the spacetime little group in $D = n + 2$ dimensions is $SO(n) \cong SO(A_n)$, as described in section 2). This is the natural generalisation of the magic square formula given in (1.1); the largest subalgebra of $\mathfrak{so}(A_n)_{ST}$ that respects spacetime transformations generates the U-duality. See Figure 1 for the magic pyramid of U-duality groups described by (1.3), and Figure 2 for the ranks of the corresponding cosets, which we include to highlight the curious pattern they follow.

The pyramid formula may also be understood geometrically. As observed in [42] for the exceptional cases, the $D = 3$ Freudenthal magic square can be regarded as the isometries of the division algebraic projective spaces $(A_N L \otimes A_N R)^{P2}$. Here we are being rather heuristic - for more detailed and elegant treatments of magic square projective geometry see [34, 43–45] and the references therein. In essence the pyramid algebra describes the isometries of special submanifolds of these projective spaces. On tensoring SYM multiplets in $D > 3$, we must identify a diagonal $A_n$ subalgebra to be associated with spacetime. This can be thought of as introducing an $A_n$-structure on the $SO(N_L + N_R)$ that acts (in the spinor representation) on the tangent space $(A_N L \otimes A_N R)^2$ at each point on the projective plane. This splits the projective space into two pieces, one internal and one spacetime. The isometries of the internal component yield the magic pyramid, while the remaining symmetries generate the spacetime little group.

Rather than SYM one might also consider “squaring” the $D = 3, 4, 6$ conformal multiplets: super Chern-Simons-matter (CSm), SYM and tensor, respectively [14]. This yields another magic pyramid, as described in section 4, which we will refer to as the conformal pyramid. See Figure 3. It has the remarkable property that its faces are also given by the known $D = 3$ magic square. For example,

---

2We neglect the translation generators of $ISO(D - 2)$ since they annihilate physical states. Note, throughout we do not distinguish the special orthogonal group from its double cover (SO vs. Spin) for typographical clarity. Of course, this is an important distinction and we hope that this rather non-trivial abuse of notation will not cause confusion given the context.
trading the maximal super Yang-Mills in $D = 6$ for the $(2,0)$ tensor multplet swaps the resulting maximal supergravity with SO$(5,5)$ U-duality for the non-gravitational $(4,0)$ self-dual-Weyl multplet with $E_{6(6)}$ U-duality considered in [14, 46, 47]. Given the recent progress in understanding three-dimensional supergravity amplitudes as double copies of Bagger-Lambert-Gustavsson theories [48], one might anticipate applications to this line of enquiry. More speculatively, the conformal pyramid in $D = 3, 4, 6$ suggests an exotic $D = 10$ theory with global symmetry $F_4(4)$, although it would have to be highly non-conventional (even heretical) from the standard perspective on the classification of supermultiplets. For earlier appearances of $F_4$ in 10 and 11 dimensions see [49–53].

Note, in the present paper the complete Freudenthal-Rosenfeld-Tits magic square describes the U-dualities of conventional $D = 3$ supergravities. Its role here is not to be confused with its appearance in the important, and aptly named, “magic supergravities” of Günyaydin-Sierre-Townsend [54, 55]. In this context the $C, H$, and $O$ rows of the magic square (with a different set of real forms) describe the U-dualities of the magic supergravities in $D = 5, 4$ and 3 respectively. The magic square also appeared previously in a further, distinct, supersymmetric setting in [56].

In section 2 we review division algebras and the square construction, giving the details of our formulation of Table 1 which were omitted from [15]. In section 3 we briefly recall the division algebraic description of SYM and then construct the magic pyramid of supergravitites. In section 4 we introduce the conformal pyramid.
Figure 3: The conformal magic pyramid. Note, the exterior faces, up to real forms, are given by the magic square (i.e. the $4 \times 4$ base) cut across its diagonal.

2 The magic square

An algebra $A$ defined over $R$ with identity element $e_0$, is said to be composition if it has a non-degenerate quadratic form $n : A \to R$ such that,

$$n(ab) = n(a)n(b), \quad \forall \ a, b \in A,$$

where we denote the multiplicative product of the algebra by juxtaposition.

A composition algebra $A$ is said to be division if it contains no zero divisors,

$$ab = 0 \quad \Rightarrow \quad a = 0 \text{ or } b = 0,$$

in which case $n$ is positive semi-definite and $A$ is referred to as a normed division algebra. Hurwitz’s celebrated theorem states that there are exactly four normed division algebras $\{R, C, H, O\}$: the reals, complexes, quaternions and octonions, denoted respectively by $R, C, H$ and $O$.

Regarding $R \subset A$ as the scalar multiples of the identity $Re_0$ we may decompose $A$ into its “real” and “imaginary” parts $A = R \oplus A'$, where $A' \subset A$ is the subspace orthogonal to $R$. An arbitrary element $a \in A$ may be written $a = \text{Re}(a) + \text{Im}(a)$. Here $\text{Re}(a) \in Re_0, \text{Im}(a) \in A'$ and

$$\text{Re}(a) = \frac{1}{2}(a + \overline{a}), \quad \text{Im}(a) = \frac{1}{2}(a - \overline{a}),$$

where we have defined conjugation using the bilinear form,

$$\overline{a} := \langle a, e_0 \rangle e_0 - a, \quad \langle a, b \rangle := n(a + b) - n(a) - n(b).$$

$A$ quadratic norm on a vector space $V$ over a field $R$ is a map $n : V \to R$ such that: (1) $n(\lambda a) = \lambda^2 n(a), \lambda \in R, a \in V$ and (2) $\langle a, b \rangle := n(a + b) - n(a) - n(b)$ is bilinear.
An element \( a \in \mathbb{O} \) may be written \( a = a^a e_a \), where \( a = 0, \ldots, 7 \), \( a^a \in \mathbb{R} \) and \( \{ e_a \} \) is a basis with one real \( e_0 \) and seven \( e_i, i = 1, \ldots, 7 \), imaginary elements. The octonionic multiplication rule is,

\[
e_a e_b = (\delta_{a0}\delta_{bc} + \delta_{0b}\delta_{ac} - \delta_{ab}\delta_{0c} + C_{abc}) e_c,
\]

where \( C_{abc} \) is totally antisymmetric and \( C_{0bc} = 0 \). The non-zero \( C_{ijk} \) are given by the Fano plane. See Figure 4.

\[\text{Figure 4: The Fano plane. The structure constants are determined by the Fano plane,} C_{ijk} = 1 \text{ if } ijk \text{ lies on a line and is ordered according as its orientation. Each oriented line follows the rules of quaternionic multiplication. For example, } e_2 e_3 = e_5 \text{ and cyclic permutations; odd permutations go against the direction of the arrows on the Fano plane and we pick up a minus sign, e.g. } e_3 e_2 = -e_5.\]

The norm preserving algebra is defined as,

\[
\mathfrak{so}(\mathbb{A}) := \{ A \in \text{Hom}_\mathbb{R}(\mathbb{A}) | \langle Aa, b \rangle + \langle a, Ab \rangle = 0, \forall a, b \in \mathbb{A} \}. \tag{2.5}\]

The triality algebra of \( \mathbb{A} \) is defined as,

\[
\text{tri}(\mathbb{A}) := \{(A, B, C) \in \mathfrak{so}(\mathbb{A}) \oplus \mathfrak{so}(\mathbb{A}) \oplus \mathfrak{so}(\mathbb{A}) | A(ab) = B(a)b + aC(b), \forall a, b \in \mathbb{A} \}. \tag{2.6}\]

Explicitly,

\[
\begin{align*}
\text{tri}(\mathbb{R}) & \cong \emptyset, \\
\text{tri}(\mathbb{C}) & \cong \mathfrak{so}(2) \oplus \mathfrak{so}(2), \\
\text{tri}(\mathbb{H}) & \cong \mathfrak{so}(3) \oplus \mathfrak{so}(3) \oplus \mathfrak{so}(3), \\
\text{tri}(\mathbb{O}) & \cong \mathfrak{so}(8). 
\end{align*} \tag{2.7}\]

For an element \( A \in \mathfrak{so}(\mathbb{A}) \) define \( \tilde{A} \in \mathfrak{so}(\mathbb{A}) \) by

\[
\tilde{A}(a) := \overline{A(a)}, \quad a \in \mathbb{A}. \tag{2.8}\]

We can then define an order three Lie algebra automorphism

\[
\theta : \text{tri}(\mathbb{A}) \to \text{tri}(\mathbb{A}) : (A, B, C) \mapsto (\tilde{B}, C, \tilde{A}), \tag{2.9}\]

which for \( \mathbb{A} = \mathbb{O} \) interchanges the three inequivalent 8-dimensional representations of \( \mathfrak{so}(\mathbb{O}) \).

Given two normed division algebras \( \mathbb{A}_L \) and \( \mathbb{A}_R \) we can define on

\[
\mathfrak{L}_3(\mathbb{A}_L, \mathbb{A}_R) := [\text{tri}(\mathbb{A}_L) \oplus \text{tri}(\mathbb{A}_R)]_{00} + (\mathbb{A}_L \otimes \mathbb{A}_R)_{01} + (\mathbb{A}_L \otimes \mathbb{A}_R)_{10} + (\mathbb{A}_L \otimes \mathbb{A}_R)_{11} \tag{2.10}\]

a \( \mathbb{Z}_2 \times \mathbb{Z}_2 \) graded Lie algebra structure following, with a slight modification to accommodate the required real forms, Barton and Sudbery [23]. First, \( \text{tri}(\mathbb{A}_L) \) and \( \text{tri}(\mathbb{A}_R) \) are Lie subalgebras. For
elements $T_L = (A_L, B_L, C_L)$ in tri($A_L$) and $(a \otimes b, 0, 0)$, $(0, a \otimes b, 0)$, and $(0, 0, a \otimes b)$ in 3($A_L \otimes A_R$), the commutators are given by the natural action of tri($A_L$),

$$
[T_L, (a \otimes b, 0, 0)] = (A_L(a) \otimes b, 0, 0),
$$

$$
[T_L, (0, a \otimes b, 0)] = (0, B_L(a) \otimes b, 0),
$$

$$
[T_L, (0, 0, a \otimes b)] = (0, 0, C_L(a) \otimes b).
$$

Similarly for $T_R = (A_R, B_R, C_R)$ in tri($A_R$),

$$
[T_R, (a \otimes b, 0, 0)] = (a \otimes A_R(b), 0, 0),
$$

$$
[T_R, (0, a \otimes b, 0)] = (0, a \otimes B_R(b), 0),
$$

$$
[T_R, (0, 0, a \otimes b)] = (0, 0, a \otimes C_R(b)).
$$

For two elements belonging to the same summand ($A_L \otimes A_R$)$_{ij}$ in (2.10) the commutator is defined using the natural map

$$
\wedge^2 (A_L \otimes A_R)_i \rightarrow \wedge^2 A_L \otimes \wedge^2 A_R \rightarrow \text{tri}(A_L) \oplus \text{tri}(A_R),
$$

where the first arrow uses the norm on $A_L$ and $A_R$. Explicitly,

$$
[(a \otimes b, 0, 0), (a' \otimes b', 0, 0)] = \langle a, a' \rangle T_{b,b'}^{R} + \langle b, b' \rangle T_{a,a'}^{L},
$$

$$
[(0, a \otimes b, 0), (0, a' \otimes b', 0)] = -\langle a, a' \rangle \theta T_{b,b'}^{R} - \langle b, b' \rangle \theta T_{a,a'}^{L},
$$

$$
[(0, 0, a \otimes b), (0, 0, a' \otimes b')] = -\langle a, a' \rangle \theta^2 T_{b,b'}^{R} - \langle b, b' \rangle \theta^2 T_{a,a'}^{L}.
$$

Here $T : \wedge^2 A \rightarrow \text{tri}(A) : (a, a') \mapsto T_{a,a'}$ is defined by

$$
T_{a,a'} := (S_{a,a'}, R_{a'}R_{\pi} - R_{a}R_{\pi'}, L_{a'}L_{\pi} - L_{a}L_{\pi'}),
$$

where

$$
S_{a,a'}(b) = \langle a, b \rangle a' - \langle a', b \rangle a, \quad L_{a}(b) = ab, \quad R_{a}(b) = ba.
$$

Finally, we have

$$
[(a \otimes b, 0, 0), (0, a' \otimes b', 0, 0)] = (0, 0, a \otimes b \otimes a' \otimes b'),
$$

$$
[(0, 0, a \otimes b), (a' \otimes b', 0, 0)] = (0, a \otimes a' \otimes b \otimes b'),
$$

$$
[(0, a \otimes b, 0), (0, 0, a' \otimes b')] = -(a \otimes a' \otimes b \otimes b').
$$

With these commutators the magic square formula (2.10) describes the Lie algebras of the groups presented in Table 1. The simplest way to check that these definitions yield the correct non-compact real forms is by comparison to the conventions of Barton and Sudbery [23], which are known to give the magic square of compact real forms. Recall, a non-compact real form $\mathfrak{g}_{nc}$ of a complex semi-simple Lie algebra $\mathfrak{g}_C$ admits a symmetric decomposition $\mathfrak{g}_{nc} = \mathfrak{h} + \mathfrak{p}$, where $\mathfrak{h}$ is the maximal compact subalgebra. If a compact real form $\mathfrak{g}_c$ shares with some non-compact real form $\mathfrak{g}_{nc}$ a common subalgebra, $\mathfrak{g}_{nc} = \mathfrak{h} + \mathfrak{p}$ and $\mathfrak{g}_c = \mathfrak{h} + \mathfrak{p}'$, and the brackets in $[\mathfrak{h}, \mathfrak{p}]$ are the same as those in $[\mathfrak{h}, \mathfrak{p}']$, but equivalent brackets in $[\mathfrak{p}, \mathfrak{p}]$ and $[\mathfrak{p}', \mathfrak{p}']$ differ by a sign, then $\mathfrak{h}$ is the maximal compact subalgebra of $\mathfrak{g}_{nc}$. This observation is sufficient to confirm that our construction yields the real forms in Table 1 and we can identify

$$
\mathcal{L}_1(A_L, A_R) := [\text{tri}(A_L) \oplus \text{tri}(A_R)]_{00} + (A_L \otimes A_R)_{01}
$$

as the maximal compact subalgebra. The corresponding compact subgroups are presented in Table 2.
### 3 The magic pyramid

#### 3.1 Super Yang-Mills over R, C, H, O

The key to constructing the magic pyramid is to write the appropriate Yang-Mills theories over R, C, H, O and then consider the symmetries of the “squared” theories. The Lagrangian for \((n+2)\)-dimensional \(\mathcal{N} = 1\) SYM with gauge group \(G\) over the division algebra \(\mathbb{A}_n\) is given by

\[
\mathcal{L}(\mathbb{A}_n) = -\frac{1}{4} F_{\mu \nu}^A F^{A \mu \nu} - \text{Re}(i \lambda^A \bar{\sigma}^\mu D_\mu \lambda^A), \quad \lambda \in \mathbb{A}_n^2,
\]

where the covariant derivative and field strength are given by the usual expressions

\[
D_{\mu} \lambda^A = \partial_{\mu} \lambda^A + g f_{BC} A_{\mu} B^C,
\]

\[
F_{\mu \nu}^A = \partial_{\mu} A_{\nu}^A - \partial_{\nu} A_{\mu}^A + g f_{BC} A_{\mu}^B A_{\nu}^C,
\]

with \(A = 0, \ldots, \dim[G]\). The \(\{\sigma^\mu\}\) are a basis for \(\mathbb{A}_n\)-valued Hermitian matrices - the straightforward generalisation of the usual complex Pauli matrices to all four normed division algebras, satisfying the usual Clifford algebra relations. We can use these to write the supersymmetry transformations:

\[
\delta A^A_{\mu} = \text{Re}(i \lambda^A \bar{\sigma}^\mu), \quad \delta \lambda^A = \frac{1}{4} F_{\mu \nu}^A \sigma^\mu (\bar{\sigma}^\nu \epsilon).
\]

Note, since the components \(\lambda^A\) are anti-commuting we are dealing with the algebra of octonions defined over the Grassmanns.

By dimensionally reducing these theories using the Dixon-halving techniques of [41], we arrive at a master Lagrangian for SYM in \(D = n + 2\) with \(\mathcal{N}\) supersymmetries written over the division algebra \(\mathbb{A}_{n\mathcal{N}}\). The division algebra associated with spacetime \(\mathbb{A}_n\) is viewed as a subalgebra of \(\mathbb{A}_{n\mathcal{N}}\). The resulting Lagrangian is:

\[
\mathcal{L}(\mathbb{A}_n, \mathbb{A}_{n\mathcal{N}}) = -\frac{1}{4} F_{\mu \nu}^A F^{A \mu \nu} - \frac{1}{2} D_{\mu} \phi^A D^\mu \phi^A - \text{Re}(i \lambda^A \bar{\sigma}^\mu D_\mu \lambda^A) - \text{Re}(i \lambda^A \bar{\sigma}^\mu D_\mu \lambda^A) - \frac{1}{16} g^2 f_{BC} A_{\mu}^B f_{DE}^A (\phi^B \phi^D + \phi^D \phi^B) (\phi^C \phi^E + \phi^E \phi^C),
\]

where \(\lambda \in \mathbb{A}_{n\mathcal{N}}^2\) (so we have \(\mathcal{N}\) spacetime spinors, each valued in \(\mathbb{A}_n^2\)) and \(\phi\) is a scalar field taking values in \(\phi \in \mathbb{A}_n^c\), the subspace of \(\mathbb{A}_{n\mathcal{N}}\) orthogonal to the \(\mathbb{A}_n\) subalgebra. The \(\{\bar{\sigma}^\mu\}\) are still a basis for \(\mathbb{A}_n\)-valued Hermitian matrices, again, with \(\mathbb{A}_n\) viewed as a division subalgebra of \(\mathbb{A}_{n\mathcal{N}}\).

The supersymmetry transformations in this language are

\[
\delta A^A_{\mu} = \text{Re}(i \lambda^A \bar{\sigma}^\mu),
\]

\[
\delta \phi^A = -\frac{i}{2} \text{tr} (\epsilon (\lambda^A \bar{A} - \epsilon \lambda^A) A^A_{\mu}),
\]

\[
\delta \lambda^A = \frac{1}{4} F_{\mu \nu}^A \sigma^\mu (\bar{\sigma}^\nu \epsilon) + \frac{1}{2} \sigma^\mu (D_\mu \phi^A \epsilon) + \frac{1}{4} f_{BC} A_{\mu}^A \phi^C (\phi^B \epsilon).
\]
where the subscript $A_n^C$ refers to the projection onto this subspace and

$$\varepsilon := \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$  \hspace{1cm} (3.6)

The important result is that we can write $\mathcal{N} = 1$ SYM in $D = n + 2$ over the division algebra $\mathbb{A}_n$, and that if we wish to double the amount of supersymmetry we Dickson-double the division algebra. For example, if we start with $\mathcal{N} = 1$ SYM in $D = 4$ over $\mathbb{C}$, then $\mathcal{N} = 2$ will be written over $\mathbb{H}$ and $\mathcal{N} = 4$ will be written over $\mathbb{O}$.

It is also useful to consider the little group representations of the fields in the division algebraic Yang-Mills theories. The little group in $D = n + 2$ dimensions is $SO(n)$. When $\mathcal{N} = 1$, SYM contains a single vector and its fermionic partner, which may each be represented as an element of $\mathbb{A}_n$, with the little group transforming them via the natural action of $SO(A_n)$. For example, in $D = 10$ we have an octonion representing the vector, transforming as the $\mathbb{O}_8$ of $SO(8)$, while the spinor is represented by another octonion, transforming as the $\mathbb{O}_8$. As noted in [41], the overall (little group plus internal) symmetry of the $\mathcal{N} = 1$ theory in $D = n + 2$ dimensions is $\text{tri}(A_n)$. If we dimensionally reduce these theories we obtain SYM with $\mathcal{N}$ supersymmetries whose overall symmetries are given by

$$\mathfrak{sym}(A_n, A_{n\mathcal{N}}) := \{ (A, B, C) \in \text{tri}(A_{n\mathcal{N}}) \mid [A, \mathfrak{so}(A_n)_{ST}] = 0 \ \forall A \notin \mathfrak{so}(A_n)_{ST} \}$$  \hspace{1cm} (3.7)

where $\mathfrak{so}(A_n)_{ST}$ is the subalgebra of $\mathfrak{so}(A_{n\mathcal{N}})$ that acts as orthogonal transformations on $A_n \subset A_{n\mathcal{N}}$. The division algebras used in each dimension and the corresponding $\mathfrak{sym}$ algebras are summarised in Table 3. The on-shell content of each SYM theory can then be summarised as:

- an $A_{n\mathcal{N}}$ element of bosons: a vector in $A_n$ and scalars in $A_n^C$, giving $A_n \oplus A_n^C = A_{n\mathcal{N}}$
- an $A_{n\mathcal{N}}$ element of fermions: $\mathcal{N}$ spacetime fermions each valued in $A_n$.

| $A_n \setminus A_{n\mathcal{N}}$ | $O$ | $H$ | $C$ | $R$ |
|---------------------------------|-----|-----|-----|-----|
| $O$                             | $\mathfrak{so}(8)_{ST}$ |     |     |     |
| $H$                             | $\mathfrak{so}(4)_{ST} \oplus \mathfrak{sp}(1) \oplus \mathfrak{sp}(1)$ | $\mathfrak{so}(4)_{ST} \oplus \mathfrak{sp}(1)$ |     |     |
| $C$                             | $\mathfrak{so}(2)_{ST} \oplus \mathfrak{su}(4)$ | $\mathfrak{so}(2)_{ST} \oplus \mathfrak{sp}(1) \oplus \mathfrak{so}(2)$ | $\mathfrak{so}(2)_{ST} \oplus \mathfrak{so}(2)$ |     |
| $R$                             | $\mathfrak{so}(4)$ | $\mathfrak{so}(4) \oplus \mathfrak{sp}(1)$ | $\mathfrak{so}(2) \oplus \mathfrak{so}(2)$ | $\emptyset$ |

Table 3: A table of algebras: $\mathfrak{sym}(A_n, A_{n\mathcal{N}})$. This lets us read off the spacetime and internal symmetries in each Yang-Mills theory. For example, one can see the familiar R-symmetries in $D = 4$: $U(1)$, $U(2)$ and $SU(4)$ for $\mathcal{N} = 1, 2, 4$, respectively. Note that the symmetries in $D = 3$ are entirely internal and that they include the R-symmetry as a subgroup (these are actually the symmetries of the theories after dualising the vector to a scalar, to be discussed in the following section).

3.2 The $D = 3$ magic square of supergravities

In $D = 3$ the spacetime algebra is $A_1 = \mathbb{R}$, so the SYM master Lagrangian (3.4) describes $\mathcal{N}$ real two-component Majorana spinors $\lambda_\alpha$, $\alpha = 1, 2$, written as a single $A_{\mathcal{N}}$-valued object $\lambda_\alpha$, as well as an $\mathbb{R}$-valued vector and an $\text{Im} A_{\mathcal{N}}$-valued scalar field. Tensoring the multiplets of left ($L$) and right ($R$) Yang-Mills theories, as in [15], we obtain the off-shell field content:

$$g_{\mu\nu} \in \mathbb{R}, \quad \Psi_\mu^\alpha \in \left( A^L_{\mathcal{N}_L} \right), \quad \varphi \in \left( A^L_{\mathcal{N}_L} \otimes A^R_{\mathcal{N}_R} \right), \quad \lambda_\alpha \in \left( A^L_{\mathcal{N}_L} \otimes A^R_{\mathcal{N}_R} \right).$$  \hspace{1cm} (3.8)
In three dimensions the R-valued graviton and $A_{N_L} \oplus A_{N_R}$-valued gravitino carry no degrees of freedom, but indicate that we have found the field content of a supergravity theory with $N = N_L + N_R$ supersymmetries. On-shell the $(A_{N_L} \otimes A_{N_R})^2$-valued scalar and Majorana spinor each have $2(N_L \times N_R)$ degrees of freedom.

| $A_{N_L} \setminus A_{N_R}$ | R          | C          | H          | O          |
|-----------------------------|------------|------------|------------|------------|
| $N' = 2, f = 4$             | $N = 3, f = 8$ | $N' = 5, f = 16$ | $N = 9, f = 32$ |             |
| $G = SL(2, R)$              | $G = SU(2, 1)$ | $G = USp(4, 2)$ | $G = E_{6(-20)}$ |             |
| $H = SO(2)$                 | $H = SO(3) \times SO(2)$ | $H = SO(5) \times SO(3)$ | $H = SO(9)$ |             |
| $N' = 3, f = 8$             | $N = 4, f = 16$ | $N = 6, f = 32$ | $N = 10, f = 64$ |             |
| $G = SU(2, 1)$              | $G = SU(2, 1)^2$ | $G = SU(4, 2)$ | $G = E_{6(-14)}$ |             |
| $H = SO(3) \times SO(2)$   | $H = SO(3)^2 \times SO(2)$ | $H = SO(6) \times SO(3) \times SO(2)$ | $H = SO(10) \times SO(2)$ |             |
| $N' = 5, f = 16$            | $N = 6, f = 32$ | $N = 8, f = 64$ | $N = 12, f = 128$ |             |
| $G = USp(4, 2)$             | $G = SO(4, 2)$ | $G = SO(8, 4)$ | $G = E_{7(-5)}$ |             |
| $H = SO(5) \times SO(3)$   | $H = SO(6) \times SO(3) \times SO(2)$ | $H = SO(8) \times SO(3) \times SO(2)$ | $H = SO(12) \times SO(3)$ |             |
| $N' = 9, f = 32$            | $N = 10, f = 64$ | $N = 12, f = 128$ | $N = 16, f = 256$ |             |
| $G = E_{6(-20)}$            | $G = E_{6(-14)}$ | $G = E_{7(-5)}$ | $G = E_{8(8)}$ |             |
| $H = SO(9)$                 | $H = SO(10) \times SO(2)$ | $H = SO(12) \times SO(3)$ | $H = SO(16)$ |             |

Table 4: Pyramid base ($D = 3$ supergravity). The first row of each entry indicates the amount of supersymmetry $N$ and the total number of degrees of freedom $f$. The second (third) row indicates the U-duality group $G$ (the maximal compact subgroup $H \subset G$) and its dimension. The scalar fields in each case parametrise the coset $G/H$, where $\dim_G(G/H) = f/2$. The

The maximal compact subgroups $H$ of the magic square of U-dualities $G$ are those given in the reduced magic square presented in Table 2. These are the largest linearly-realised global symmetries under which $\Psi_\mu, \varphi$ and $\chi$ transform as a vector, spinor and conjugate spinor; $A_{N_L} \oplus A_{N_R}$ and $(A_{N_L} \otimes A_{N_R})^2$ are precisely the representation spaces of the vector and (conjugate) spinor. For example, in the maximal case of $A_{N_L} \otimes A_{N_R} = 0$, the U-duality is $G = E_{8(8)}$ and we have the $16, 128$ and $128^c$ of its maximal compact subgroup $H = SO(16)$.

We can better understand the origin of the magic $D = 3$ U-dualities if we consider the symmetries of their parent Yang-Mills theories. If we set the coupling constant $g$ in (3.4) to zero then we may dualise the vector to a scalar and write the Lagrangian as:

$$\mathcal{L}(A_N) = -\frac{1}{2} \partial_\mu \phi^A \partial^\mu \phi^A - i \lambda^A \sigma^\mu \partial_\mu \lambda^A,$$

(3.9)

where $\phi$ and $\lambda^A$ each take values in $A_N$ (note that in $D = 3$ we do not need to take the real part of the fermion kinetic term since the sigma matrices are real and symmetric). The supersymmetry transformations become:

$$\delta \phi^A = -i \epsilon^\dagger \varepsilon \lambda^A, \quad \delta \lambda^A = \frac{1}{2} \sigma^\mu \varepsilon \partial_\mu \phi^A \epsilon.$$

(3.10)

Equations (3.9) and (3.10) enjoy a symmetry whose Lie algebra is $\mathfrak{so}(R, A_N) \cong \mathfrak{tri}(A_N)$. Looking at the theory it is clear why this is the case, since transformations preserving (3.10) coincide with the definition of $\mathfrak{tri}(A_N)$; that is to say, we might initially try to transform the three $A_N$-valued objects $\phi, \lambda$ and $\epsilon$ by three independent $SO(A_N)$ rotations, but the supersymmetry transformations constrain these three rotations to satisfy the definition (2.8).

Tensoring the on-shell field content, $\phi_{L/R}, \lambda_{L/R}$, of the dualised Yang-Mills theories we obtain an $(A_{N_L} \otimes A_{N_R})^2$-valued scalar and spinor,

$$\varphi \in \left( \phi_L \otimes \phi_R \right) \left( \lambda_L \otimes \lambda_R \right), \quad \chi \in \left( \phi_L \otimes \lambda_R \right) \left( \lambda_L \otimes \phi_R \right).$$

(3.11)
The \( \text{tr}(A_{N_L}) \) and \( \text{tr}(A_{N_R}) \) symmetries of the two Yang-Mills theories act on these doublets as the (operator valued) \( 2 \times 2 \) matrices:

\[
\begin{pmatrix}
\text{tr}(A_{N_L}) \otimes 1 & 0 \\
0 & \text{tr}(A_{N_L}) \otimes 1
\end{pmatrix}, \quad
\begin{pmatrix}
1 \otimes \text{tr}(A_{N_R}) & 0 \\
0 & 1 \otimes \text{tr}(A_{N_R})
\end{pmatrix}.
\]

(3.12)

Since we have arranged the fields of the squared theory into doublets we might also consider the off-diagonal rotations

\[
\begin{pmatrix}
0 & e^*_a \otimes e^{*a} \\
e_a \otimes e^a & 0
\end{pmatrix}.
\]

(3.13)

The total algebra of linear transformations is then given by

\[
\mathcal{L}_1(A_L, A_R) := \text{tr}(A_{N_L}) \oplus \text{tr}(A_{N_R}) + A_{N_L} \otimes A_{N_R},
\]

(3.14)

which is precisely that of the reduced magic square. It is interesting to note that the off-diagonal transformations of (3.13) take Yang-Mills fermions into Yang-Mills bosons, and vice versa, but are bosonic generators in the supergravity theory. It is tempting to identify these generators with \( Q_L \otimes Q_R \), where \( Q_{L/R} \) are the supercharges of the left and right Yang-Mills theories, as this correctly reproduces basic structure of transformations (3.13). However, the derivative in the supersymmetry transformations appears to spoil this correspondence.

The full non-linear U-duality groups \( G \) are fixed by the field content and \( H \) symmetries, as described in [42]. The groups we find are, of course, those of the magic square in Table 1. We summarise the theories of the \( D = 3 \) magic square in Table 4.

### 3.3 Generalisation to \( D = 4, 6, 10 \)

To generalise the results above to \( D = 4, 6, 10 \) we first consider the simplest example in \( D = 4 \): tensoring two \( \mathcal{N} = 1 \) SYM multiplets \( (A_\mu, \lambda) \) to obtain \( \mathcal{N} = 2 \) supergravity. Counting the degrees of freedom \( (4 \times 4 = 16) \) tells us that we must have a gravity multiplet coupled to one hypermultiplet, so the field content we expect is: \( (g_{\mu\nu}, 2\Psi_\mu, A_\mu, 2\chi, 4\phi) \). We will square on-shell, so the Yang-Mills fields are represented by the complex numbers (helicity states):

\[
A_{L/R}, \lambda_{L/R} \in \mathbb{C}_{L/R}.
\]

(3.15)

Squaring and arranging into doublets of bosons and fermions then gives us the \((\mathbb{C} \otimes \mathbb{C})^2\) valued objects:

\[
B = \begin{pmatrix}
A_L \otimes A_R \\
\lambda_L \otimes \lambda_R
\end{pmatrix} \quad \text{and} \quad F = \begin{pmatrix}
A_L \otimes \lambda_R \\
\lambda_L \otimes A_R
\end{pmatrix}.
\]

(3.16)

Consider acting on these with \( \mathcal{L}_1(C_L, C_R) := \text{tr}(C_L) \oplus \text{tr}(C_R) + C_L \otimes C_R \). A basis for \( \text{tr}(C_L) \cong \mathfrak{so}(2) \oplus \mathfrak{so}(2) \) is given by the matrices

\[
\begin{pmatrix}
i \otimes 1 & 0 \\
0 & i \otimes 1
\end{pmatrix}, \quad
\begin{pmatrix}
i \otimes 1 & 0 \\
0 & -i \otimes 1
\end{pmatrix},
\]

(3.17)

while \( \text{tr}(C_R) \) has

\[
\begin{pmatrix}
1 \otimes i & 0 \\
0 & 1 \otimes i
\end{pmatrix}, \quad
\begin{pmatrix}
1 \otimes i & 0 \\
0 & -1 \otimes i
\end{pmatrix},
\]

(3.18)

and the \( C_L \otimes C_R \) part consists of the four anti-Hermitian matrices

\[
\begin{pmatrix}
0 & 1 \otimes 1 \\
-1 \otimes 1 & 0
\end{pmatrix}, \quad
\begin{pmatrix}
0 & -i \otimes 1 \\
-i \otimes 1 & 0
\end{pmatrix}, \quad
\begin{pmatrix}
0 & -1 \otimes i \\
-1 \otimes i & 0
\end{pmatrix}, \quad
\begin{pmatrix}
0 & i \otimes i \\
-i \otimes i & 0
\end{pmatrix}.
\]

(3.19)

When working with \( \mathbb{C} \otimes \mathbb{C} \) it is convenient to define the quantities

\[
1_\pm := \frac{1}{2}(1 \otimes 1 \mp i \otimes i), \quad i_\pm := \frac{1}{2}(i \otimes 1 \pm 1 \otimes i),
\]

(3.20)
which each separately behave like the basis of $\mathbb{C}$:

\[ i_\pm^2 = -1_\pm, \quad 1_\pm i_\pm = i_\pm, \quad 1_\pm^2 = 1_\pm, \quad (3.21) \]

but annihilate one another:

\[ 1_\pm 1_\mp = 0, \quad 1_\pm i_\mp = 0, \quad i_\pm i_\mp = 0. \quad (3.22) \]

Rewriting the 8 matrices above in terms of this basis we obtain the following set:

\[ i_\pm \mathbb{1}, \ i_\pm \sigma^1, \ 1_\pm \varepsilon, \ i_\pm \sigma^3, \]
\[ i_- \mathbb{1}, \ i_- \sigma^1, \ 1_- \varepsilon, \ i_- \sigma^3, \quad (3.23) \]

where the sigmas and epsilon refer to the usual Pauli matrices (as opposed to the generalised Pauli matrices defined previously):

\[ \sigma^1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \varepsilon = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \quad \sigma^3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \quad (3.24) \]

This set of matrices evidently generates $\text{SU}(2) \times \text{SU}(2) \times \text{U}(1) \times \text{U}(1) \cong \text{SO}(4) \times \text{SO}(2) \times \text{SO}(2)$, as stated in the magic square in Table 2.

However, the original Yang-Mills theories have a symmetry under the transformations

\[ \delta A_{L/R} = i \theta_{ST} A_{L/R}, \quad \delta \psi_{L/R} = \frac{1}{2} i \theta_{ST} \psi_{L/R} + i \theta_{L/R}^L \psi_{L/R}. \quad (3.25) \]

where $\theta_{ST}$ is the spacetime $\text{U}(1)_{ST}$ little group parameter and $\theta_{L/R}^L$ are those of the Yang-Mills R-symmetries. Note that these correspond to $\text{tr}(C_{L/R}) \cong \mathfrak{so}(2) \oplus \mathfrak{so}(2)$. The variation of the fermionic doublet under $\text{U}(1)_{ST}$ and the R-symmetries is thus

\[ \delta F = \left[ \theta_{ST} \left( i \otimes \frac{1}{2} i \otimes 1 \right) + \theta_{ST}^L \left( \frac{1}{2} 1 \otimes i \otimes i \right) + \theta_{ST}^R \left( 0 \otimes 0 \otimes 0 \right) + \frac{1}{2} (1 \otimes i \otimes 0) \right] F. \quad (3.26) \]

Written in terms of the $i_{\pm}$ basis we find

\[ \delta F = \left[ \theta_{ST} \left( \frac{3}{2} i_+ \mathbb{1} + \frac{1}{2} i_- \sigma^3 \right) + \frac{1}{2} \theta_{ST}^L (\mathbb{1} - \sigma^3) (i_+ + i_-) + \frac{1}{2} \theta_{ST}^R (\mathbb{1} + \sigma^3) (i_+ - i_-) \right] F. \quad (3.27) \]

What has emerged are the $\text{U}(1)_{ST}$ transformations for the gravitinos and spin-$\frac{1}{2}$ fermions and two internal $\text{U}(1)$ pieces. Since $\mathbb{C} \otimes \mathbb{C}$ is not a division algebra, it contains zero divisors; it is interesting to note their role here in ensuring that the spin-$\frac{3}{2}$ and spin-$\frac{1}{2}$ fields each receive their appropriate little group transformations. Now the largest symmetry that acts on this doublet must be the subalgebra of $\mathfrak{su}(\mathcal{C}_L, \mathcal{C}_R)$ that commutes with these spacetime generators. All the matrices commute with $i_+ \mathbb{1}$, but $i_- \sigma^1$ and $1_- \varepsilon$ do not commute with $i_- \sigma^3$, so we are forced to discard these generators. The remaining matrices generate:

\[ \text{U}(1)_{ST} \times (\text{U}(1) \times \text{U}(1) \times \text{SU}(2))_U, \quad (3.28) \]

where the subscript $U$ denotes the maximal compact subgroup of the U-duality. This is the entry found in the pyramid. Again, note how the gravitino transforms as a doublet under the SU(2) but, because of the $i_+$, the spin-$\frac{1}{2}$ fields are singlets, as required in the supergravity theory. The Yang-Mills R-symmetries have been absorbed into the U-duality group. A similar analysis for the bosonic fields in the theory shows that we do indeed obtain a graviton, a vector and two scalars, which transform as a singlet, a singlet and doublet under the SU(2), just as one would hope.

In the general case for $D = n + 2$, we begin with a pair of Yang-Mills theories with $\mathcal{N}_L$ and $\mathcal{N}_R$ supersymmetries written over the division algebras $\mathbb{A}_{n\mathcal{N}_L}$ and $\mathbb{A}_{n\mathcal{N}_R}$, respectively. Taking the little

\footnote{The objects $i_{\pm}$ act as projection operators dividing $\mathbb{C} \otimes \mathbb{C}$ into two 2-dimensional subspaces, on which $i_{\pm}$ act as complex structures, so that $\mathbb{C} \otimes \mathbb{C} \cong \mathbb{C} \otimes \mathbb{C}$.}
group fields we may then write all the bosons of the left (right) theory as a single element $B_L \in \mathcal{A}_{n_{NL}}$ ($B_R \in \mathcal{A}_{n_{NR}}$), and similarly for the fermions $F_L \in \mathcal{A}_{n_{NL}}$ ($F_R \in \mathcal{A}_{n_{NR}}$). After tensoring we arrange the resulting supergravity fields into a bosonic doublet and a fermionic doublet,

$$B = \begin{pmatrix} B_L \otimes B_R \\ F_L \otimes F_R \end{pmatrix}, \quad F = \begin{pmatrix} B_L \otimes F_R \\ F_L \otimes B_R \end{pmatrix},$$

(3.29)

just as we did in $D = 3$. The largest algebra that can act on these doublets is $\mathfrak{L}_1(\mathcal{A}_{n_{NL}}, \mathcal{A}_{n_{NR}})$, but an $\mathfrak{so}(\mathcal{A}_n)_{ST}$ subalgebra of this corresponds to spacetime transformations, so we must restrict $\mathfrak{L}_1(\mathcal{A}_{n_{NL}}, \mathcal{A}_{n_{NR}})$ to the subalgebra that commutes with $\mathfrak{so}(\mathcal{A}_n)_{ST}$. Imposing this condition actually turns out to be sufficient to find all the correct U-dualities. The Lie algebra $u$ of the U-duality group of a $D = n + 2$ supergravity theory obtained by tensoring Yang-Mills theories with $\mathcal{N}_L$ and $\mathcal{N}_R$ supersymmetries is thus given by:

$$u \cong \mathfrak{u}(\mathcal{A}_n, \mathcal{A}_{n_{NL}}, \mathcal{A}_{n_{NR}}) := \left\{ u \in \mathfrak{L}_3(\mathcal{A}_{n_{NL}}, \mathcal{A}_{n_{NR}}) - \mathfrak{so}(\mathcal{A}_n)_{ST} \mid [u, \mathfrak{so}(\mathcal{A}_n)_{ST}] = 0 \right\}. \tag{3.30}$$

To evaluate this formula for different values of $\mathcal{N}_L, \mathcal{N}_R$ and $n$, we require only to decompose the adjoint representations of groups given by $\mathfrak{L}_3(\mathcal{A}_{n_{NL}}, \mathcal{A}_{n_{NR}})$ under the $\mathfrak{so}(\mathcal{A}_n)_{ST}$ subgroup and discard all pieces that transform non-trivially under $\mathfrak{so}(\mathcal{A}_n)_{ST}$.

Locating the spacetime subgroup in the supergravity just amounts to tracking it back to the Yang-Mills theories by decomposing $\text{tri}(\mathcal{A}_{n_{NL}}) \otimes \mathcal{N}_L, \mathcal{N}_R$ into $\mathfrak{so}(\mathcal{A}_n, \mathcal{A}_{n_{NL}})$. The systematic process for finding the U-dualities can then be summarised by the following recipe:

- Decompose $\text{tri}(\mathcal{A}_{n_{NL}}) \otimes \mathcal{N}_L, \mathcal{N}_R$ into $\mathfrak{so}(\mathcal{A}_n, \mathcal{A}_{n_{NL}}) \otimes \mathfrak{so}(\mathcal{A}_n, \mathcal{A}_{n_{NR}})$,
- Identify $\mathfrak{so}(\mathcal{A}_n)$ as the diagonal subgroup in $\mathfrak{so}(\mathcal{A}_n)_{ST_L} \times \mathfrak{so}(\mathcal{A}_n)_{ST_R}$,
- Discard all generators that transform non-trivially under $\mathfrak{so}(\mathcal{A}_n)_{ST}$.

For the maximal compact subgroups $H$, we just follow the same recipe with $\mathfrak{L}_1(\mathcal{A}_{n_{NL}}, \mathcal{A}_{n_{NR}})$.

To extract the spacetime representations contained in the doublets $B, F$ we decompose the spinor and conjugate spinor representations of $\mathfrak{L}_1(\mathcal{A}_{n_{NL}}, \mathcal{A}_{n_{NR}})$ with respect to $H \otimes \mathfrak{so}(\mathcal{A}_n)_{ST}$. In the following we summarise each layer, demonstrating the calculation of the U-duality and tabulating the resulting supergravities.

**D = 4 layer:** As the archetypal example, consider squaring $D = 4, \mathcal{N} = 4$ Yang-Mills to obtain $\mathcal{N} = 8$ supergravity, which we know should have $E_{7(7)}$ as its U-duality, with a maximal compact subgroup of SU(8). Following the recipe above we decompose

$$E_{7(7)} \supset \text{SO}(8) \times \text{SO}(8) \supset \text{SU}(4) \times \text{U}(1) \times \text{SU}(4) \times \text{U}(1) \supset \begin{array}{c} (15, 1)_{00} + (1, 1)_{00} + (1, 15)_{00} + (1, 1)_{00} \\
+ (6, 1)_{20} + (1, 6)_{02} + (1, 6)_{02} + (6, 1)_{20} \\
+ (4, 4)_{11} + (4, 4)_{11} + (4, 4)_{11} + (4, 4)_{11} \\
+ (1, 1)_{22} + (1, 1)_{22} + (1, 1)_{22} + (1, 1)_{22} \\
+ (1, 6)_{20} + (6, 1)_{02} + (6, 1)_{02} + (6, 6)_{00} \end{array},$$

(3.31)

where we have split the compact and non-compact generators with the square brackets. Adding and subtracting the U(1) charges, the first is the charge under U(1)$_{ST}$, while the second is an internal
Discarding those generators carrying non-trivial U(1) \(_{ST}\) charge along with U(1) \(_{ST}\) itself, we recognise the decomposition of \(E_{7(7)}\) into SU(4) \(_{\times}\) SU(4) \(_{\times}\) U(1):

\[
133 \to [(1, 1)_0 + (15, 1)_0 + (1, 15)_0 + (1, 1)_0 + (6, 1)_{2-2} + (1, 6)_{-2} + (6, 1)_{-2-2} + (4, 4)_{20} + (4, 4)_{-20}],
\]

(3.32) where we have suppressed the U(1) \(_{ST}\) spacetime charges, which are all zero. The compact pieces form the maximal compact subgroup SU(8):

\[
63 \to (1, 1)_0 + (15, 1)_0 + (1, 15)_0 + (4, 4)_2 + (\overline{4}, \overline{4})_{-2}.
\]

(3.34)

To extract the field content we simply decompose the 128 (\(B\)) and 128' (\(F\)) of SO(16) with respect to SU(8) \(_{\times}\) U(1) _\(_{ST}\):

\[
128 \to 14 + 1_{-4} + 28_2 + 28_{-2} + 70_0
\]

\[
128' \to 8_3 + \overline{8}_{-3} + 56_1 + 56_{-1},
\]

(3.35) which yields the expected supermultiplet \(g_{\mu\nu}, 8\Psi_\mu, 28A_\mu, 56\chi, 70\phi\). Repeating this process for the other theories in \(D = 4\) gives Table 5. These theories were previously obtained in [10] by consistently truncating to the untwisted sector of the low-energy effective field theory of type II superstrings on factorised orbifolds, revealing their double-copy structure. The magic \(D = 4, \mathcal{N} = 2\) supergravities were also discussed in this context. In particular, the quarternionic theory originates from a non-factorisable \(\mathbb{Z}_2\)-orbifold compactification [10].

---

\(^5\)Further branching the SU(8) representations above with respect to SU(4) \(_{\times}\) SU(4) we can see their Yang-Mills origins more clearly.
Table 5: First floor of pyramid ($D = 4$ supergravity). The first row of each entry indicates the amount of supersymmetry $\mathcal{N}$ and the total number of degrees of freedom $f$. The second (third) row indicates the U-duality group $G$ (the maximal compact subgroup $H \subset G$) and its dimension. The scalar fields in each case parametrise the coset $G/H$.

$D = 6$ layer: In $D = 6$ the spacetime little group is $SO(4)_{ST} \cong Sp(1)^+_{ST} \times Sp(1)^-_{ST}$, and the Yang-Mills multiplets available are $(\mathcal{N}_+, \mathcal{N}_-) = (1,0), (0,1), (1,1)$, written over $H, H, O$, respectively. Here we summarise the tensoring of these multiplets. For

$$[(\mathcal{N}_+, \mathcal{N}_-)_{SYM}] 	imes [(\mathcal{N}_+, \mathcal{N}_-)_{SYM}]$$

we have:

$$[(1,1)_{SYM}] \times [(1,1)_{SYM}] = [(2,2)_{sugra}]$$

$$[(1,1)_{SYM}] \times [(0,1)_{SYM}] = [(1,2)_{sugra}]$$

$$[(1,0)_{SYM}] \times [(1,0)_{SYM}] = [(2,0)_{sugra} + (2,0)_{tensor}]$$

The details of the above tensorings are given in Appendix A. See also [14]. The chiral $(1,2)_{sugra}$ is anomalous and adding the required compensating matter extends the theory to $(2,2)_{sugra}$ [59]. Similarly, the $[(2,0)_{sugra} + (2,0)_{tensor}]$ theory is anomalous since the unique anomaly free $\mathcal{N} = 2, 0$ theory consists of one $(2,0)_{sugra}$ multiplet coupled to 21 $(2,0)_{tensor}$ multiplets as obtained by compactifying $D = 10$ Type IIB supergravity on a $K3$. The additional 20 $(2,0)_{tensor}$ multiplets required to cancel the anomaly can be included by considering an alternative tensoring with $\mathcal{N}_L = (2,0)$ and $\mathcal{N}_R = (0,0)$,

$$[(2,0)_{tensor}] \times [B_{\mu\nu}^R + 21\phi^R] = [(2,0)_{sugra} + 21(2,0)_{tensor}]$$

where $B_{\mu\nu}^R$ is anti-selfdual and transforms as a $(1,3)$ under the space-time little group.

Note, we could have also chosen the left/right $\mathcal{N} = 1$ multiplets to have opposite chiralities yielding,

$$[(1,0)_{SYM}] \times [(0,1)_{SYM}] = [(1,1)_{sugra}]$$

To demonstrate the calculation of the U-duality groups, consider the maximal case, $[(1,1)_{SYM}] \times [(1,1)_{SYM}] = [(2,2)_{sugra}]$. Following the recipe gives

$$E_{8(8)} \supset SO(8) \times SO(8) \supset Sp(1)^+_{STL} \times Sp(1)^-_{STL} \times Sp(1) \times Sp(1) \times Sp(1) \times Sp(1) \times Sp(1)^+_{STR} \times Sp(1)^-_{STR} \times Sp(1)$$

248 $\rightarrow$ \begin{align*}
(3,1,1,1,1,1,1,1) &+ (1,3,1,1,1,1,1,1) + (1,1,3,1,1,1,1,1) + (1,1,1,3,1,1,1,1) + (1,1,1,1,3,1,1,1) \\
&+ (1,1,1,1,1,3,1,1) + (1,1,1,1,1,1,3,1) + (1,1,1,1,1,1,1,3) \\
&+ (1,2,2,1,1,2,1,1,2) + (2,1,1,2,1,1,2,1,2) + (2,1,1,1,2,1,2,1,2) + (2,1,2,1,1,2,1,2,1) \\
&+ (2,2,2,2,1,1,1,1,1,1) + (1,1,1,1,1,2,2,2,2) \\
&+ (2,2,1,1,1,2,1,2,1) + (2,2,1,1,1,1,2,2) + (1,1,2,2,2,2,1,1) + (1,1,2,2,2,1,1,2) \\
&+ (2,1,2,1,2,1,1,2,1) + (2,1,2,1,1,2,1,2,1) + (1,2,1,2,1,2,1,1,2) + (1,2,1,2,1,1,2,1,2,1). \end{align*}
where, as before, the square brackets partition the generators into those that live in the maximal compact subgroup and those that do not. Once again, it appears that we have two copies of the sixth), leading to:

\[ E_{8(8)} \supset \text{Sp}(1)^+_{ST_L} \times \text{Sp}(1)^-_{ST_R} \times \text{Sp}(1)^-_{ST_T} \times \text{Sp}(1)^+_{ST_T} \times \text{Sp}(1) \times \text{Sp}(1) \times \text{Sp}(1) \times \text{Sp}(1) \]

where the first and second slots label \( \text{Sp}(1)^+_{ST_T} \times \text{Sp}(1)^-_{ST_T} \). Truncating all pieces that are not spacetime singlets we find the remaining generators are those of the following decomposition:

\[ \text{SO}(5, 5) \supset \text{SO}(5) \times \text{SO}(5) \supset \text{Sp}(1) \times \text{Sp}(1) \times \text{Sp}(1) \times \text{Sp}(1) \]

\[ 45 \rightarrow [(3, 1, 1, 1, 1) + (1, 3, 1, 1, 1) + (1, 1, 3, 1, 1) + (1, 1, 1, 3, 1) + (1, 1, 1, 1, 1)] \]

\[ + [(3, 1, 2, 1, 2) + (1, 1, 2, 1, 2) + (2, 2, 2, 1, 2)] \]

Note that the generators in the first pair of square brackets belong to the maximal compact subgroup \( \text{SO}(5) \times \text{SO}(5) \), and those in the second pair are all non-compact, so we do indeed find the maximally non-compact real form \( \text{SO}(5, 5) \), familiar from the dimensional reduction of Type II supergravity on \( T^4 \).

Applying this procedure to the other two slots in \( D = 6 \) we recover Table 6 where we have chosen to tensor SYM mutipltets of opposite chiralities in the \( H \otimes H \) case, resulting in pure \( \mathcal{N} = (1, 1) \) supergravity with \( G/H \) given by \( \text{Sp}(1) \times \text{Sp}(1) \times \text{O}(1,1)/\text{Sp}(1) \times \text{Sp}(1) \). On the other hand, for matching chiralities we obtain \( \mathcal{N} = (2, 0) \) supergravity coupled to a single tensor multiplet with \( G/H \) given by \( \text{Sp}(2) \times \text{O}(1,1)/\text{Sp}(2) \).

Although we do not consider them directly here, it should be noted that the magic \( D = 6, \mathcal{N} = (1,0) \) supergravities (which come coupled to 2, 3, 5, 9 tensor multiplets and 2, 4, 8, 16 vector multiplets, respectively, as well as hypers) are closely related to the magic square and constitute the parent theories of the magic \( D = 5, 4, 3 \) supergravities. See [60] and the references therein.

| \( \mathcal{A}_{4N_L} \setminus \mathcal{A}_{4N_R} \) | \( H \) | \( O \) |
|---|---|---|
| \( \mathcal{N} = (1, 1), f = 64 \) | \( \mathcal{N} = (1, 2), f = 128 \) |
| \( G = \text{Sp}(1) \times \text{Sp}(1) \times \text{O}(1,1) \) | \( G = \text{SU}^*(4) \times \text{Sp}(1) \) |
| \( H = \text{Sp}(1) \times \text{Sp}(1) \) | \( H = \text{Sp}(1) \times \text{Sp}(2) \) |
| \( \mathcal{N} = (2, 1), f = 128 \) | \( \mathcal{N} = (2, 2), f = 256 \) |
| \( G = \text{SU}^*(4) \times \text{Sp}(1) \) | \( G = \text{SO}(5, 5) \) |
| \( H = \text{Sp}(2) \times \text{Sp}(1) \) | \( H = \text{Sp}(2) \times \text{Sp}(2) \) |
Table 7: Magic square of $D = 10$ supergravity theories. The left-hand (right-hand) table is obtained by tensoring SYM of opposing (matching) chiralities, which is equivalent to applying a triality to the magic pyramid formula. Of course, there is no room for matter couplings in $D = 10$.

$D = 10$ layer: In $D = 10$ we just have $\mathcal{N} = 1$ SYM over $O$, whose on-shell field content is a pair of octonions: a vector $\mathbf{8}_v$ and spinor $\mathbf{8}_s$ or $\mathbf{8}_c$ of $SO(8)_{ST}$. When each Yang-Mills theory contains an $\mathbf{8}_s$ we apply the recipe as above:

$$
E_{8(8)} \supset SO(8)_{ST_L} \times SO(8)_{ST_R}
$$

$$
248 \to \left[ (28, 1) + (1, 28) + (8_s, 8_c) \right] + \left[ (8_s, 8_s) + (8_v, 8_v) \right],
$$

(3.43)

where, once again, we use square brackets to divide the generators into those that belong to the maximal compact subgroup $SO(16)$ and those that do not. We should again take the diagonal subgroup in $SO(8)_{ST_L} \times SO(8)_{ST_R}$, taking tensor products of the representations appearing in the two slots:

$$
E_{8(8)} \supset SO(8)_{ST}
$$

$$
248 \to \left[ 28 + 28 + 1 + 28_v + 35_v \right] + \left[ 1 + 28_s + 35_s + 1 + 28_v + 35_v \right].
$$

(3.44)

Discarding all but the spacetime singlets leaves us with a copy of $SL(2, \mathbb{R})$ decomposed into the trivial group,

$$
3 \to \left[ 1 \right] + \left[ 1 + 1 \right],
$$

(3.45)

so we recover the familiar $SL(2, \mathbb{R})$ U-duality of Type IIB supergravity.

To obtain Type IIA we just exchange $\mathbf{8}_s \leftrightarrow \mathbf{8}_c$ in the right-hand slots of Equation 3.43:

$$
E_{8(8)} \supset SO(8)_{ST_L} \times SO(8)_{ST_R}
$$

$$
248 \to \left[ (28, 1) + (1, 28) + (8_c, 8_s) \right] + \left[ (8_s, 8_c) + (8_v, 8_v) \right],
$$

(3.46)

which becomes

$$
E_{8(8)} \supset SO(8)_{ST}
$$

$$
248 \to \left[ 28 + 28 + 8_v + 56_v \right] + \left[ 8_s + 56_v + 1 + 28_v + 35_v \right],
$$

(3.47)

leaving a single non-compact $\mathbf{1}$ to generate $O(1, 1)$. This is the correct U-duality, since there is only a single scalar in Type IIA, which lives on the scalar manifold $\mathbb{R} \cong O(1, 1)/\mathbb{I}$.

### 3.4 Complex and Quaternionic Structures

It is interesting to look at the magic pyramid of maximal compact subgroups, shown in Figure 5. The striking feature is that the $D = 3$ square is built from orthogonal groups, the $D = 4$ square from unitary groups and the $D = 6$ square from symplectic groups. This is no mere coincidence: $SO(N)$ is the group of rotations in a real $N$-dimensional space, $U(N)$ is the group of rotations in a complex $N$-dimensional space and $Sp(N)$ is the group of rotations in a quaternionic $N$-dimensional space $^{34,61}$.

$$
\mathfrak{so}(N) = \{ X \in \mathbb{R}[N] \mid X^\dagger = -X \},
$$

$$
\mathfrak{u}(N) = \{ X \in \mathbb{C}[N] \mid X^\dagger = -X \},
$$

$$
\mathfrak{sp}(N) = \{ X \in \mathbb{H}[N] \mid X^\dagger = -X \},
$$

(3.48)
where $A[N]$ denotes the set of $N \times N$ matrices with entries $6$ in $A$. Note that (up to factors of SO(3) and SO(2)) as we climb the dotted lines of the pyramid, corresponding to dimensional oxidation, the maximal compact subgroups go as \( \text{SO}(N_D=3) = \text{SO}(2N_D=4) \rightarrow \text{SU}(N_D=4) \) when ascending from \( D = 3 \) to \( D = 4 \). These groups are of course the supergravity R-symmetries: \( \text{SO}(N) \) in \( D = 3 \) and \( \text{SU}(N) \) in \( D = 4 \). The R-symmetry groups are the automorphisms of the supersymmetry algebra, with the supercharges $Q$ transforming in the defining representation. Restricting the $D = 3$ symmetries by demanding that they commute with the single generator $J$ of $\text{u}(1)_{ST}$ amounts to demanding that the generators of $\text{SO}(2N_D=4)$ commute with a complex structure, as $J$ satisfies $J^2Q = -1Q$. From this point of view it is clear why we find $\text{SO}(2N_D=4) \rightarrow \text{SU}(N_D=4)$, since in general

$$u(N) \cong \left\{ u \in \mathfrak{so}(2N) \mid [u, J] = 0, \ J^2 = -1, \ J \in \mathfrak{so}(2N) \right\},$$

(3.49)

where the $U(1)$ factor of $U(N) \cong SU(N) \times U(1)$ is generated by the complex structure $J$ itself. In our case the complex structure is the generator of the spacetime little group $U(1)_{ST}$.

To understand the different R-symmetry groups as we ascend from $D = 3$ to $D = 6$ we require the notion of a quaternionic structure. This is a triple of $4N \times 4N$ matrices $J_1$, $J_2$ and $J_3 := J_1J_2$ satisfying the quaternion algebra:

$$J_iJ_j = -\delta_{ij}1 + \varepsilon_{ijk}J_k, \quad i, j, k = 1, 2, 3,$$

(3.50)

which we find belong to the Lie algebra $\mathfrak{so}(4N)$. Just as $U(N)$ may be seen as the subgroup of $\text{SO}(2N)$ that commutes with a complex structure, symplectic groups are the subgroups of $\text{SO}(4N)$ that commute with the $J_i$:

$$\text{sp}(N) \cong \{ u \in \mathfrak{so}(4N) \mid [u, J_1] = [u, J_2] = 0, \ J_1^2 = J_2^2 = -1, \ J_iJ_j = -J_jJ_i, \ J_i \in \mathfrak{so}(4N) \}$$

(3.51)

Incidentally, this explains our insistence on referring to $\text{SU}(2)$ as $\text{Sp}(1)$, the group generated by $1 \times 1$ anti-Hermitian quaternionic matrices.

Figure 5: Magic pyramid of maximal compact subgroups

(O)
factors as being generated by a quaternionic structure. For example, in the maximal (\(\mathcal{N}_+, \mathcal{N}_-\) = (2, 2) supergravity we have 16 supercharges, divided equally between the two chiralities, splitting the possible SO(16) group of transformations into SO(8) \(\times\) SO(8). Putting a quaternionic structure on each of these SO(8) factors leaves us with an overall symmetry Sp(2) \(\times\) Sp(2) \(\times\) Sp(1)\(^+_\mathcal{S}\) \(\times\) Sp(1)\(^{-\mathcal{S}}\).

3.5 S-duality of \(\mathcal{N} = 4\) SYM and supergravity

When the tensor product involves at least one \(\mathcal{N} = 4\) SYM multiplet, it is tempting to speculate that the exact SL(2, Z) S-duality of \(\mathcal{N} = 4\) SYM contributes to the S-duality of the resulting supergravity. How this might actually work remains unclear, especially given the exchange of the gauge group for its GNO (Goddard, Nuyts, and Olive) duals, on the other hand, singlets. The NS-NS potentials are identified as those originating from \(\phi_L \otimes A_{R\nu}\) and \(A_{L\mu} \otimes \phi_R\) products, while the RR sector potentials come from spinor-spinor products \(\lambda_L \otimes \lambda_R\) (consistent with the familiar type II story in \(D = 10\)). This yields the following counting of NS-NS and RR potentials and dual potentials,

\[
\begin{align*}
[\mathcal{N} = 4]_R & \quad [\mathcal{N} = 2]_R & \quad [\mathcal{N} = 1]_R & \quad [\mathcal{N} = 0]_R \\
[\mathcal{N} = 4]_L & \quad 2 \times 12 + 2 \times 16 & \quad 2 \times 8 + 2 \times 8 & \quad 2 \times 6 + 2 \times 4 & \quad 2 \times 6 + 0 \\
[\mathcal{N} = 2]_L & \quad 2 \times 4 + 2 \times 4 & \quad 2 \times 2 \times 2 + 2 \times 2 & \quad 2 \times 2 + 0 & \quad (3.52) \\
[\mathcal{N} = 1]_L & \quad 0 + 2 \times 1 & \quad 0 + 0 & \quad 0 + 0 \\
[\mathcal{N} = 0]_L & \quad 0 + 0 & \quad & \quad \end{align*}
\]

Decomposing the U-duality representations carried by the gauge potentials and their duals under the product of S and T dualities we have,

\[
\begin{align*}
[\mathcal{N} = 4]_R & \quad [\mathcal{N} = 2]_R & \quad [\mathcal{N} = 1]_R & \quad [\mathcal{N} = 0]_R \\
[\mathcal{N} = 4]_L & \quad E_7(7) \supset & \quad \text{SO}^*(12) \supset & \quad \text{SU}(1, 5) \supset & \quad \text{SL}(2) \times \text{SO}(6) \supset \\
& \quad \text{SL}(2) \times \text{SO}(6, 6) & \quad \text{SL}(2) \times \text{SO}(3) \times \text{SO}(2, 6) & \quad \text{SL}(2) \times \text{SO}(2) \times \text{SO}(6) & \quad \text{SL}(2) \times \text{SO}(6) \\
& \quad 56 \rightarrow & \quad 32 \rightarrow & \quad 20 \rightarrow & \quad (2, 6) \rightarrow \\
& \quad (2, 12) + (1, 32) & \quad (2, 1, 8_s) + (1, 2, 8_s) & \quad (2, 6)_b + (1, 4)_3 + (1, 3)_{-3} & \quad (2, 6) \\
[\mathcal{N} = 2]_L & \quad \text{SL}(2) \times \text{SO}(6, 2) \supset & \quad \text{SL}(2)_S \times \text{SL}(2)_L^2 \times \text{SU}(2)^2 & \quad \text{U}(1, 3) \supset & \quad \text{SL}(2) \times \text{SO}(2) \supset \\
& \quad (2, 8) \rightarrow & \quad (2, 2, 2, 1, 1) + (1, 2, 1, 2, 2) & \quad (2, 1, 1) + (1, 2)_{-1} & \quad 2_1 + 2_2^{-1} \rightarrow \\
[\mathcal{N} = 1]_L & \quad \text{U}(1, 2) \supset & \quad \text{SL}(2)_L \times \text{U}(1) & \quad \text{SL}(2) \supset & \quad \text{SL}(2) \supset \\
& \quad 1_1 + 1_2^{-1} \rightarrow & \quad 1_1 + 1_2^{-1} & \quad & \quad \\
[\mathcal{N} = 0]_L & \quad & & \quad & \quad \\
& & & \quad & \quad \\
\end{align*}
\]

demonstrating a splitting of the potentials into their NS-NS and RR sectors consistent with their tensor origin.

Note, the SL(2, R) factor appearing in the U-duality of \([\mathcal{N} = 2]_L \otimes [\mathcal{N} = 2]_R\), which yields \(\mathcal{N} = 4\) supergravity coupled to two vector multiplets, is not, as one might naturally assume, the S-duality.

\[^7\text{One possibility is that the left/right gauge groups must be GNO duals. We thank Neil Lambert for sharing this suggestion.}\]
group since it mixes NS-NS and RR, as can be checked by regarding it as a consistent truncation of $\mathcal{N} = 8$ supergravity. However, the $\text{SL}(2,\mathbb{R})$ S-duality inside $E_{7(7)}$ is retained inside the $\text{SO}(6,2)$ factor of the $\mathcal{N} = 4$ theory since $\text{SL}(2,\mathbb{R}) \times \text{SO}(6,2)$ is not a subgroup of $\text{SO}(6,6)$. Of course, the strong-weak dualities of $\mathcal{N} = 2$ SYM theories are not exact and, as such, their role in this context is even less clear.

4 The conformal magic pyramid

Rather than uniformly tensoring SYM in each dimension we may consider instead the conformal theories: CSm in $D = 3$, SYM in $D = 4$ and tensor multiplets in $D = 6$. It is not clear what the appropriate theory should be in $D = 10$ and we leave this question for future work.

The tensorings of CSm and SYM in $D = 3$ yield the same results so it is only the tensor multiplets in $D = 6$ that we need to treat here. As for left/right SYM, composing tensor multiplets with opposing chiralities we obtain pure supergravity,

\[
[(2,0)^L_{\text{tensor}}] \times [(0,2)^R_{\text{tensor}}] = [(2,2)_{\text{sugra}}],
\]

\[
[(2,0)^L_{\text{tensor}}] \times [(0,1)^R_{\text{tensor}}] = [(2,1)_{\text{sugra}}],
\]

\[
[(1,0)^L_{\text{tensor}}] \times [(0,1)^R_{\text{tensor}}] = [(1,1)_{\text{sugra}}],
\]

reproducing Table 6.

On the other hand, for left/right tensor multiplets with matching chiralities we obtain the exotic non-gravitational SD-Weyl (self-dual-Weyl) multiplets coupled to tensor multiplets,

\[
[(2,0)^L_{\text{tensor}}] \times [(2,0)^R_{\text{tensor}}] = [(4,0)_{\text{SD-Weyl}}]
\]

\[
[(2,0)^L_{\text{tensor}}] \times [(1,0)^R_{\text{tensor}}] = [(3,0)_{\text{SD-Weyl}}]
\]

\[
[(1,0)^L_{\text{tensor}}] \times [(1,0)^R_{\text{tensor}}] = [(2,0)_{\text{SD-Weyl}}] + [(2,0)_{\text{tensor}}].
\]

The $[(2,0)^L_{\text{tensor}}] \times [(2,0)^R_{\text{tensor}}] = [(4,0)_{\text{SD-Weyl}}]$ squaring is given explicitly in Table 12. This theory is developed in some detail in [46,47]. It is non-gravitational with highest spin field transforming as the $(5,1)$ of the little group $\text{Sp}(1)_{ST} \times \text{Sp}(1)_{ST}$. The terminology “SD-Weyl” derives from the fact that the $(5,1)$ representation has the symmetry properties of a four-dimensional Euclidean self-dual Weyl tensor when written with $\text{SO}(4)$ indices, as described in [46].

The scalars of the SD-Weyl multiplets appearing in (4.2) parameterise the following cosets

\[
[(4,0)_{\text{SD-Weyl}}] \frac{E_{6(6)}}{\text{Sp}(4)},
\]

\[
[(3,0)_{\text{SD-Weyl}}] \frac{\text{SU}^*(6)}{\text{Sp}(3)},
\]

\[
[(2,0)_{\text{SD-Weyl}}] + [(2,0)_{\text{tensor}}] \frac{O(5,1)}{\text{Sp}(2)}.
\]

Hence, by exchanging SYM multiplets with tensor multiplets the $D = 6$ level of the pyramid is adjusted,

\[
\frac{\text{SO}(5,5)}{\text{Sp}(2) \times \text{Sp}(2)} \rightarrow \frac{E_{6(6)}}{\text{Sp}(4)}
\]

\[
\frac{\text{SU}^*(4) \times \text{Sp}(1)}{\text{Sp}(2) \times \text{Sp}(1)} \rightarrow \frac{\text{SU}^*(6)}{\text{Sp}(3)}
\]

\[
\frac{\text{Sp}(1)^2 \times \text{O}(1,1)}{\text{Sp}(1)^2 \times \mathbb{Z}_2} \rightarrow \frac{\text{O}(5,1)}{\text{Sp}(2)}
\]

Unless they come coupled to extra matter multiplets. For example, the $\text{SU}(2)$ $\mathcal{N} = 2$ SYM coupled to four hypermultiplets transforming in the fundamental is believed to be exact [63].
while the remaining levels are left unchanged. Interestingly, this has the consequence that the exterior faces of the pyramid, as presented in Figure 3, are given by the original magic square cut across its diagonal.

An intriguing property of the tensor multiplets and SD-Weyl multiplets above is that every field is a scalar under Sp(1)$_{ST}$, so the spacetime symmetry is essentially just Sp(1)$_{ST}^+$ as long as we multiply tensor multiplets of a single chirality$^9$. Mathematically the conformal pyramid is perhaps the most natural, since we can understand:

- the $D = 4$ square as the Freudenthal-Rosenfeld-Tits magic square restricted to the subgroups that commute with a complex structure
- the $D = 6$ square as the Freudenthal-Rosenfeld-Tits magic square restricted to the subgroups that commute with a single quaternionic structure (as opposed to the pair of quaternionic structures we found for the SYM-squared pyramid).

See Figure 6. From this perspective a method for obtaining the $(1, 0)$ tensor multiplet

$$B^+ \in \text{Im } \mathbb{H} \sim (3, 1), \quad \phi \in \text{Re } \mathbb{H} \sim (1, 1), \quad \lambda \in \mathbb{H} \sim (2, 2) \quad \text{of } \text{Sp}(1)^\perp_{ST} \times \text{Sp}(1)$$

from the $(1, 0)$ Yang-Mills multiplet

$$A \in \mathbb{H} \sim (2, 2, 1), \quad \lambda \in \mathbb{H} \sim (2, 1, 2) \quad \text{of } \text{Sp}(1)^\perp_{ST} \times \text{Sp}(1)^\perp_{ST} \times \text{Sp}(1)$$

would be to identify Sp$(1)^+_{ST} \sim$ Sp$(1)^\perp_{ST}$ and tensor product: $2 \times 2 = 3 + 1$. So when $\mathbb{A}_{4N} = \mathbb{H}$ the tensor multiplet is just that of Yang-Mills with positive and negative chiralities identified. The group Sp$(1)^+_{ST}$ just acts as orthogonal transformations on Im $\mathbb{H}$. For the $(2, 0)$ tensor multiplet, $\mathbb{A}_{4N} = \mathbb{O}$, we have an Sp$(1)^\perp_{ST} \times \text{Sp}(2)$ overall symmetry (which simply comes from restricting SO$(8)$ to the subgroup commuting with a quaternionic structure). This motivates the following definition of $\tilde{s}\chi m$, our notation for the overall symmetry algebras of the conformal theories in $D = 3, 4, 6$:

$$\tilde{s}\chi m(\mathbb{A}_n, \mathbb{A}_{nN}) := \{ (A, B, C) \in \text{tr}(\mathbb{A}_{nN}) | [A, g_{ST}] = 0 \ \forall A \notin g_{ST} \}, \quad (4.7)$$

where $a, b \in \mathbb{A}_{nN}$ and $g_{ST}$ is the subalgebra of $\mathfrak{so}(\mathbb{A}_{nN})$ that acts as orthogonal transformations on $\mathbb{A}_n \subset \mathbb{A}_{nN}$ when $n \neq 4$ and acts as orthogonal transformations on $\text{Im } \mathbb{A}_n = \text{Im } \mathbb{H} \subset \mathbb{A}_{4N}$ when $n = 4$. The fact that this definition is not democratic in the division algebras might seem unnatural, but the special treatment for $\mathbb{H}$ just represents the additional requirement that the $D = 6$ theories be completely chiral; the resulting algebras agree with $s\chi m$ in $D = 3, 4$ but $\tilde{s}\chi m(\mathbb{H}, \mathbb{H}) \cong \text{sp}(1)_{ST} \oplus \text{sp}(1)$ and $\tilde{s}\chi m(\mathbb{H}, \mathbb{O}) \cong \text{sp}(1)_{ST} \oplus \text{sp}(2)$.

The U-dualities $u$ of the conformal pyramid are then given by

$$u \cong \text{ConfPyr}(\mathbb{A}_n, \mathbb{A}_{nN}, \mathbb{A}_{nN'}) := \left\{ u \in \mathfrak{L}_3(\mathbb{A}_{nN}, \mathbb{A}_{nN'}) - g_{ST} \big| [u, g_{ST}] = 0 \right\}. \quad (4.8)$$

In practice we find the groups of the conformal pyramid (in $D = 3, 4, 6$) using the following method:

- Decompose $\text{tr}(\mathbb{A}_{nN}) \oplus \text{tr}(\mathbb{A}_{nN'})$ into $\tilde{s}\chi m(\mathbb{A}_n, \mathbb{A}_{nN}) \oplus \tilde{s}\chi m(\mathbb{A}_n, \mathbb{A}_{nN'})$,
- Identify $g_{ST}$ as the diagonal subalgebra of $g_{STL} \oplus g_{STR}$,
- Discard all generators that transform non-trivially under the spacetime symmetries $g_{ST}$.

Once again, to find the maximal compact subgroups we just replace $\mathfrak{L}_3(\mathbb{A}_{nN}, \mathbb{A}_{nN'})$ with $\mathfrak{L}_1(\mathbb{A}_{nN}, \mathbb{A}_{nN'})$ in the above. While this method does not tell us how to obtain the U-duality in $D = 10$, we venture some speculations on this matter as part of our closing remarks in section 5.

$^9$Up until this point we have not mentioned $D = 5$, but we note an interesting point about it here. Since the non-trivial little group in the $D = 6$ chiral theories is Sp$(1)^\perp_{ST}$, it becomes clear why the maximal $[(4, 0)_{3D, W_{3D}}]$ theory in $D = 6$ and the maximal supergravity in $D = 5$ both have $E_{6(6)}$ as their U-duality groups: both may be obtained by restricting $E_{8(8)}$ to the subgroup that commutes with SO$(3)_{ST} \cong \text{Sp}(1)^\perp_{ST}$. 

21
4.1 Barton-Sudbery-style formula

For the compact subgroups $h$ it is instructive to look at which generators in each of the three terms of $\mathfrak{L}_1(\mathfrak{A}_n^L, \mathfrak{A}_n^R) := \text{tri}(\mathfrak{A}_n^L) \oplus \text{tri}(\mathfrak{A}_n^R) + (\mathfrak{A}_n^L \otimes \mathfrak{A}_n^R)$ commute with $\mathfrak{g}_{ST}$. For the first two terms,

$$[\text{tri}(\mathfrak{A}_n^L) \oplus \text{tri}(\mathfrak{A}_n^R), \mathfrak{g}_{ST}] = 0 \quad (4.9)$$

is solved by

$$\text{int}(\mathfrak{A}_n^L) \oplus \delta_2n\mathfrak{u}(1)^{ST_L} \oplus \text{int}(\mathfrak{A}_n^R) \oplus \delta_2n\mathfrak{u}(1)^{ST_R}, \quad (4.10)$$

where

$$\text{int}(\mathfrak{A}_n, \mathfrak{A}_n^{L/R}) = \overline{\text{sym}}(\mathfrak{A}_n, \mathfrak{A}_n^{L/R}) \otimes \mathfrak{g}_{ST_L/R}. \quad (4.11)$$

The $\delta_2n\mathfrak{u}(1)^{ST_L/R}$ terms come from the fact that when $n = 2$, $\mathfrak{g}_{ST} \cong \mathfrak{u}(1)$ and so commutes with itself. The group we identify as spacetime in the supergravity theory is the diagonal subgroup of the left and right spacetime groups; subtracting this we are left with

$$\text{int}(\mathfrak{A}_n^L) \oplus \text{int}(\mathfrak{A}_n^R) \oplus \delta_2n\mathfrak{u}(1). \quad (4.12)$$

Finally we denote the solution to

$$[\mathfrak{A}_n^L \otimes \mathfrak{A}_n^R, \mathfrak{g}_{ST}] = 0 \quad (4.13)$$

(slightly schematically) by

$$\mathfrak{A}_n(\mathfrak{A}_n^L \otimes \mathfrak{A}_n^R) \quad (4.14)$$

since its dimension is $n\mathfrak{N}_L\mathfrak{N}_R$, and this notation captures its essence; we have made $\mathfrak{A}_n^L$ look like $\sim \mathfrak{A}_n\mathfrak{A}_n^{L/R}$, and then brought the left and right pieces together, identifying a diagonal $\mathfrak{A}_n$ algebra. Putting all of this together we arrive at a Barton-Sudbery-style formula for the compact subgroups of the conformal pyramid

$$h = \text{int}(\mathfrak{A}_n, \mathfrak{A}_n^L) \oplus \text{int}(\mathfrak{A}_n, \mathfrak{A}_n^R) + \mathfrak{A}_n(\mathfrak{A}_n^L \otimes \mathfrak{A}_n^R) + \delta_2n\mathfrak{u}(1), \quad (4.15)$$

Figure 6: Conformal magic pyramid of maximal compact subgroups
which allows one to build up the symmetries of the squared theories from those of the left/right conformal theories.

5 Conclusions

We began with the observation developed in [41] that \( \mathcal{N} = 2^m \)-extended SYM theories in \( D = n + 2 \) spacetime dimensions may be formulated with a single Lagrangian and single set of transformation rules, but with spacetime fields valued in \( \mathbb{A}_n \mathcal{N} \). This perspective reveals a role for the triality algebras; once the fields are regarded as division algebras consistency with supersymmetry constrains the possible space of transformations to \( \text{sym}(\mathbb{A}_n, \mathbb{A}_n \mathcal{N}) \subseteq \text{tri}(\mathbb{A}_n \mathcal{N}) \).

Tensoring left/right SYM multiplets valued in \( \mathbb{A}_n \mathcal{N}/\mathcal{N}_L/\mathcal{N}_R \) then naturally leads us to \( \mathcal{N}_L + \mathcal{N}_R \) supergravity multiplets with spacetime fields valued in \( \mathbb{A}_n \mathcal{N}_L \otimes \mathbb{A}_n \mathcal{N}_R \). For \( D = 1 + 2 \) this yields a set of supergravities with U-duality groups given by the magic square of Freudenthal-Rosenfeld-Tits. For \( n = 2, 4, 8 \), identifying a common spacetime subalgebra \( \mathbb{A}_n \) truncates the magic square to a \( 3 \times 3, 2 \times 2, \) and \( 1 \times 1 \) array of subalgebras, corresponding precisely to the U-dualities obtained by tensoring SYM in \( D = 4, 6 \) and 10, respectively. Together the four ascending squares constitute a magic pyramid of algebras defined by the magic pyramid formula \( (3.30) \). The exceptional octonionic row and column of each level is constrained by supersymmetry to give the unique supergravity multiplet. On the other hand, the interior \( 3 \times 3, 2 \times 2, 1 \times 1 \) and \( 0 \times 0 \) squares can and do admit matter couplings. These additional matter multiplets are just as required to give the U-dualities predicted by the pyramid formula. Interestingly, in these cases the degrees of freedom are split evenly between the graviton multiplet and the matter multiplets, the number of which is determined by the rule \(^{10} k = \min(\mathcal{N}_L, \mathcal{N}_R) \).

The magic pyramid supergravity theories are rather non-generic. Not only are they, in a sense, defined by the magic pyramid formula, they are also generated by tensoring the division algebraic SYM multiplets. It would therefore be interesting to explore whether they collectively possess other special properties, particularly as quantum theories, which can be traced back to their magic square origins. For example, in the maximal \( [\mathcal{N}_L = 4 \text{ SYM}] \times [\mathcal{N}_R = 4 \text{ SYM}] \) case it has been shown that \( \mathcal{N} = 8 \) supergravity is four-loop finite \(^5\), a result which cannot be attributed to supersymmetry alone. While \( \mathcal{N} = 8 \) is expected to have the best possible UV behaviour, as suggested by its connection to \( \mathcal{N} = 4 \text{ SYM} \), it could still be that the remaining magic square supergravities share some structural features due to their common gauge \( \times \) gauge origin and closely related global symmetries.

Conversely, one might also seek extensions of the magic pyramid construction which could account for more generic supergravities. The magic supergravities of Gunaydin, Sierre and Townsend \(^{54,55}\), for example, admit at least one obvious generalisation using the family of spin-factor Jordan algebras, suggesting a possible extension of the present construction by incorporating matter multiplets.

Let us return to the present treatment, now in the conformal case. In section 4 we saw that tensoring the conformal theories in \( D = 3, 4, 6 \) resulted in a pyramid with the intriguing feature that its exterior faces are given by the Freudenthal-Rosenfeld-Tits square cut across its diagonal. In particular, ascending up the maximal spine one encounters the famous exceptional sequence \( E_8(8), E_7(7), E_6(6) \), but where \( E_6(6) \) belongs to the exotic \( (4,0) \) theory in \( D = 6 \). This pattern suggests the existence of some highly exotic \( D = 10 \) theory with \( F_{4(4)} \) U-duality group \(^{11}\). We would naturally require it to be dimensionally reduce to the \( (4,0) \) theory in \( D = 6 \) on some non-trivial manifold (orbifold), consistent with scalars living in \( E_6(6)/\text{Sp}(4) \) and \( F_{4(4)}/\text{Sp}(3) \times \text{Sp}(1) \) in \( D = 6 \) and 10, respectively. The \( D = 6 \) supercharges transform as the \( 8 \) of \( \text{Sp}(4) \), which breaks to the \( (6,1) + (1,2) \) of \( \text{Sp}(3) \times \text{Sp}(1) \), leaving \( \mathcal{N} = 2, 6, 8 \) as possibilities in \( D = 10 \). Naively at least, \( \mathcal{N} = 2 \) is ruled out by the standard classification of supermultiplets \(^{64,65}\) due to the assumption that it may be dimensionally reduced to \( D = 6, \mathcal{N} = (4,0) \), since this would imply fields of helicity greater than 2 when dimensionally reducing on a 6-torus. If, however, the \( F_{4(4)} \) theory had some exotic dynamics which broke the usual spacetime

\(^{10}\)We thank Andrew Thomson for pointing out this rule. Note the subtlety in \( \mathcal{N}^+ = 0, \mathcal{N}^- = 0 \) separately. Hence, for example, \( [(1,0)] \times [(0,1)] \) has \( k = 0 \).

\(^{11}\)Note, \( F_{4(4)}/\text{Sp}(3) \times \text{Sp}(1) \) also appears in three dimensions as the scalar coset of the \( \mathcal{N} = 4 \) magic supergravity coupled to six vector multiplets. It corresponds to dimensional reduction of the \( D = 4, \mathcal{N} = 2 \) magic supergravity based on the Jordan algebra of \( 3 \times 3 \) real Hermitian matrices \(^{55}\). We thank one of the referees for bringing this observation to our attention.
little group to some subgroup this logic may not hold. Taking into account the desired $F_{4(4)}$, this line of reasoning suggests a $G_2$ little group as one possibility. These avenues will be explored elsewhere.

There is, however, an obvious alternative interpretation of the conformal pyramid including its $F_{4(4)}$ tip. The $(4,0)$ theory in $D = 6$ with $E_{6(6)}$ U-duality reduces on a circle to $D = 5$, $\mathcal{N} = 8$ supergravity, again with $E_{6(6)}$ U-duality. The same result holds for the remaining three slots of the $D = 6$ square; they each reduce to a $D = 5$ supergravity theory with very same U-duality group. This is a consequence of the fact that the $D = 6$ fields are singlets under the second factor of the little group $Sp(1) \times Sp(1)$, which therefore effectively reduces to the $D = 5$ little group $Sp(1)$. Each of the resulting $D = 5$ theories may be obtained by squaring. Hence, Figure 3 may be regarded as a squashed pyramid of U-dualities for theories in $D = 3, 4, 5, 6$. The apex is now given by the $D = 6, \mathcal{N} = (3,1)$ theory, obtained from $[[(2,0)^{tensor}_{l_{tensor}}] \times [(1,1)^{R}_{vector}], with G/H given by F_{4(4)}/Sp(3) \times Sp(1)$, as expected. Note, however, this multiplet contains gravitini but no graviton and is therefore not expected to define a consistent interacting theory.

### Acknowledgments

We would like to thank Bianca Cerchiai, Sergio Ferrara and Alessio Marrani for useful discussions. We thank John Carrasco and Lance Dixon for discussions concerning the role of S-duality. We thank Zvi Bern for his encouragement. The work of LB is supported by an Imperial College Junior Research Fellowship. The work of MJD is supported by the STFC under rolling grant ST/G000743/1.

### A  $D = 6$ Tensoring tables

In Table 8, Table 9 and Table 11, we perform the $D = 6$ SYM squaring on-shell to arrive at the supergravity and matter content. In each table the fields are shown together with their little group representations appearing in the left-handed SD-Weyl, little group for massless states. The $[(2,0)^{tensor}_{l_{tensor}}] \times [(1,1)^{R}_{vector}]$, with $G/H given by $F_{4(4)}/Sp(3) \times Sp(1)$, as expected. Note, however, this multiplet contains gravitini but no graviton and is therefore not expected to define a consistent interacting theory.

We would like to thank Zvi Bern for his encouragement. The work of LB is supported by an Imperial College Junior Research Fellowship. The work of MJD is supported by the STFC under rolling grant ST/G000743/1.

#### A.1  $D = 6$ Tensoring tables

In Table 8, Table 9 and Table 11, we perform the $D = 6$ SYM squaring on-shell to arrive at the supergravity and matter content. In each table the fields are shown together with their little group $SO(4) \cong Sp(1) \times Sp(1)$ representations. Note, we restrict to the semi-simple part of the full little group for massless states. The $[(2,0)^{tensor}_{l_{tensor}}] \times [(2,0)^{tensor}_{l_{tensor}}] = [(4,0)^{SD-Weyl}] tensoring is given as an example in Table 12. The little group representations appearing in the left-handed SD-Weyl multiplets are given by $(n,1)$, where $n = 1, 2, \ldots 5$. These irreps are carried by totally symmetric rank $n - 1$ tensors of $Sp(1)$:

$$(3,1) B_{(A_1A_2)}^{+}, \quad (4,1) C_{(A_1A_2A_3)}^{+}, \quad (5,1) D_{(A_1A_2A_3A_4)}^{+}. \quad (A.1)$$

The multiplicities are given by the dimension of the R-symmetry representation of the fields.

Consulting Table 12, we see that there are 27 self-dual two-form field strengths transforming as the fundamental 27 of $E_{6(6)}$. There are 42 scalars parametrising $E_{6(6)}/Sp(4)$. The fermionic fields, $C^{+}$, and $\lambda^{+}$ transform as the 8 and 48 of $Sp(4)$ respectively.
Table 8: $D = 6$, $[(1,1)^{L}_{SYM}] \times [(1,1)^{R}_{SYM}] = [(2,2)_{susy}]$.
