ABSTRACT Informative retrospect and inspiring prospect on various creative and interesting integrations of millimeter-wave (mm-Wave) and non-mm-Wave antennas to mobile phones from diverse and practical perspectives are innovatively and systematically presented in this article. Thus, quick and beneficial understanding of reported works can be achieved and further influential developments can be enlightened. The types of the proposed integrations include the printed circuit board (PCB) type, module type, the flexible printed circuit (FPC) type, the exterior type, the hybrid type, and the display type, which are in the discussion order of straightforwardness for solution generation. View angles from the locations, conformality, and transparency of the integration solutions are presented as well to comprehensively compare the six interesting kinds of discussed antenna integrations to mobile phones. Also, an insightful evolution of the six antenna integrations to mobile phones is illustrated as the summary to enable a clearer picture of the solution considerations, features, and trend.

INDEX TERMS 5G mobile communication, antennas, cellular phones, integrations, millimeter-wave.

I. WHY ANTENNA INTEGRATIONS?
Because of the higher requirements on wireless data rates in the era of the 5th generation mobile communications (5G) than those in 4G, the mm-Wave bands possessing wide bandwidths able to upgrade channel capacities and thus user experience in wireless communications are the core spectrum to 5G or even 6G technologies [1]–[3]. According to the 3rd generation partnership project (3GPP) [4], currently, the licensed mm-Wave bands for 5G are coded as bands n258 (24.25–27.50 GHz), n257 (26.5–29.5 GHz), n261 (27.50–28.35 GHz), n260 (37.0–40.0 GHz), n259 (39.5–43.5 GHz), and n262 (47.2–48.2 GHz). However, in addition to mm-Wave bands, non-mm-Wave bands for 5G and long-term evolution (LTE) bands are still essential to attain satisfied wireless coverage with acceptable wireless transmission rates defined by the radiocommunication sector of the international telecommunications union (ITU-R) [5]. Among the coded 5G licensed non-mm-Wave bands by the 3GPP [6], in addition to re-farmed bands, the bands n77 (3.3–4.2 GHz), n78 (3.3–3.8 GHz), and n79 (4.4–5.0 GHz) are also prevailing in most countries and areas nowadays. In other words, for 5G, the mm-Wave and non-mm-Wave bands in fact are complementary to each other for the hotspot and wide coverage scenarios described by ITU-R, respectively, to ensure and enhance user experience in 5G wireless communications. As a result, mm-Wave antennas for 5G and non-mm-Wave antennas for 5G and/or for LTE are reasonably foreseeable to co-exist in most 5G mobile phones. Besides, to support the user-experience data rate proposed by ITU-R in the non-mm-Wave bands, the technology of massive multiple-input and multiple-output (MIMO) is hence adopted, which implies more non-mm-Wave antennas should be deployed in a mobile phone to establish more channels for better wireless transmissions. Due to so limited internal space of mobile phones and more antenna quantities in mobile phones, especially the 5G ones, the integrations of mm-Wave and non-mm-Wave antennas are highly foreseeable and favorable to future mobile phones because the space occupied by various antennas is promising to get reduced through integrations. To put it differently, in addition to the
realization of the original individual wireless communication functions, the integrations of mm-Wave and non-mm-Wave antennas can further enable compelling and precious synergy, that is, the prevention from undesirable size expansion caused by antennas or even reduction in whole sizes of mobile phones. Furthermore, the integrated mm-Wave and non-mm-Wave antennas can serve as one-stop antenna total solutions to mobile phones, which can remarkably benefit the design loads, assembly complexity (i.e., the yield rates and assembly efficiencies), and even the overall costs. Therefore, the topic on integrations of mm-Wave and non-mm-Wave antennas to mobile phones has attracted much attention and wide interests. In this article, four creative and interesting types, including the module type, FPC type, exterior type, and hybrid type, for the integrations of mm-Wave and non-mm-Wave antennas to mobile phones are retrospectively presented; what’s more, the promising and innovative one, the display type, is prospectively proposed. Based on the retrospect and prospect, a promising and enlightening evolution of integrations of mm-Wave and non-mm-Wave antennas to mobile phones from diverse and pragmatic angles of views is inspiringly analyzed and depicted as well for more straightforward and insightful understanding to pave for future developments.

II. TYPES OF INTEGRATIONS

A. PCB TYPE

For past and current mobile phones, PCBs are fundamental and necessary system platforms to carries components and traces. Besides, PCBs were also popularly employed for the designs of mm-Wave antennas [7], [8] and non-mm-Wave antennas [9], [10]. Therefore, it makes certain sense to design the PCB-type integrations of mm-Wave and non-mm-Wave antennas [11]–[14] as shown in Fig. 1. The integrated design in Fig. 1(a) [12] covers two mm-Wave bands (28 GHz and 38 GHz) and five non-mm-Wave bands (2.3 GHz, 2.4 GHz, 2.5 GHz, 3.5 GHz, and 5.0 GHz) through two substrate integrated waveguides (SIWs) (individually with a 1 × 4 mm-Wave slot antenna array) reused as parts of two non-mm-Wave antennas coupled by a planar T-shaped feeding probe. In Fig. 1(b) [13], two slots on the PCB are opened to serve as the integrated antennas for mm-Wave bands (23–29 GHz) and non-mm-Wave bands (2.05–2.70 GHz). However, PCB-type antennas typically require significant clearance areas or slots on PCBs; thus, the application feasibility to practical mobile phones, especially the 5G ones with competitive phone sizes, plenty of components, and high screen-to-body ratios, generally will be obviously impacted.

B. MODULE TYPE

Because the antenna-in-package (AiP) solution is to integrate the antenna(s) and radio-frequency integrated circuit(s) (RFIC(s)) into a standard surface-mounted package [15], [16] to shorten the in-between feeding paths and thus to mitigate the corresponding path losses for better radiation performance, the AiP solution [17]–[19] nowadays is the mainstream to mm-wave antennas in terminal devices, fixed wireless access (FWA) stations, and base stations. Due to the packaging processes, the AiP solution typically is in the module type; to accomplish the discussed integrations, non-mm-wave antennas are hence rationally integrated to existing mm-wave AiP modules. In other words, the module type is a good candidate for integration solutions of mm-Wave and non-mm-Wave antennas, especially to mobile phones. To date, almost studied and commercialized 5G AiP modules for handsets are only to cover 5G mm-Wave bands. In order to expand the band coverage on 5G non-mm-Wave bands, a leading and creative module of the AiP-based design named mm-wave antennas-in-package integrating non-mm-Wave antennas (AiPiA) [20], [21] shown in Fig. 2(a) was proposed. The AiPiA module is to integrate two physical non-mm-Wave antennas for 3GPP 5G bands n78 and n79 to a 5G multi-band mm-Wave AiP module (with the low-temperature co-fired ceramic (LTCC) as the substrate) covering 3GPP 5G band n257, n261, n260, and the mm-Wave band (24.75–27.50

VOLUME XX, 2020
and antennas with two array are in the form of cavity-backed differential inverted-L antennas in the AiPiA module of a 1 × 4 mm-Wave antennas to mobile phones. The uniformly-spaced mm-Wave GHz) planned in China to realize a total solution of 5G mainstream 5G mm-Wave AiP module [17].

![Module Prototype Comparison](image)

**FIGURE 2.** (a) The X-ray image of the AiPiA module prototype (21.27 × 4.18 × 1.36 mm³) [20], (b) and (c) The size comparison between the AiPiA module prototype and a commercialized mainstream 5G mm-Wave AiP module [17]. (d) The size comparison between an LTCC-based AiPaA module prototype (19.39 × 4.18 × 1.36 mm³) [20] and a commercialized mainstream 5G mm-Wave AiP module [17].

mm-Wave and non-mm-Wave bands was reported [20], too. Moreover, to reduce the AiPiA module volume, another innovative module of AiP-based design called mm-Wave antennas-in-package as non-mm-Wave antennas (AiPaA) was presented [20], [22] to directly feed the 5G mm-Wave AiP module (also covering 3GPP 5G band n257, n261, n260, and the mm-Wave band (24.75–27.50 GHz) planned in China) by the 5G non-mm-Wave sources and feeding networks so that the 5G mm-Wave AiP modules themselves can function as virtual equivalent (i.e., no physical non-mm-Wave antennas integrated) 5G non-mm-Wave antennas for 3GPP 5G bands n78 and n79 as well to enable an even more advantageous 5G antenna total solution than the AiPiA one. The in-band isolation between the mm-Wave and virtual equivalent non-mm-Wave antennas is higher than 21.15 dB. Besides, the size comparison between a commercialized 5G mm-Wave AiP module and an AiPaA module prototype also with the LTCC substrate is shown in Fig. 2(d) [20]; the length of the proposed AiPaA module is much shorter than that of the commercialized 5G mm-Wave AiP module with the widths equal as well. Similarly, an AiPaA design derivative for both mm-Wave and non-mm-Wave MIMO functions was proposed [20], too. Furthermore, an advanced hybrid design concept through the combination of AiPiA and AiPaA designs named mm-Wave antennas-in-package integrating and as non-mm-Wave antennas (AiPiA) was presented [20] to enable a mm-Wave AiP module with even more non-mm-Wave antennas (that is, the stronger capabilities of non-mm-Wave wireless communications) in both physically integrated and virtual equivalent forms in a competitive module volume. One of the keys to the AiPiA design is the isolation between these included non-mm-Wave antennas; what’s more, when some of the mentioned non-mm-Wave antennas operate in the same bands, their envelope correlation coefficients (ECCs) are core to the wireless communication performance.

**C. FPC TYPE**

FPC antennas for non-mm-Wave bands have been popularly applied to mobile phones [23]–[25] for a long time. Also, the conformal ability of the FPCs is much better than that of the modules, which means the FPCs can better fit the curved and sleek shapes of mobile phones to further reinforce the attractiveness and competitiveness of the mobile phones. Consequently, to integrate mm-Wave and non-mm-Wave antennas based on FPCs is reasonable and promising. As shown in Fig. 3 (a) [26], a flexible integration of mm-Wave and non-mm-Wave antennas based on an FPC was presented. In the figure, the part 2 means the printed circuit board (PCB), part 10 stands for the FPC, part 100 is the flexible antenna structure, part 16 represents the extended portion (for mm-wave signal transmissions) from the FPC, parts 31 symbolize the feeding source assembly for non-mm-Wave antennas (with the part 311 as the feeding line, part 312 as the matching network, and part 313 as the feeding source), part
22 refers to the mm-Wave RFIC, parts 30 mean the physical non-mm-Wave antennas, and part 20 stands for the mm-Wave antennas. As a result, in this design, two physical non-mm-Wave antennas (parts 30) and two virtual equivalent non-mm-Wave antennas functioned by the FPC itself fed by the non-mm-Wave antenna feeding source assembly (parts 31) are integrated on the same FPC (part 10) originally for the mm-Wave antennas. Likewise, the isolation (and ECCs for antennas operating in the same bands) between the 4 integrated non-mm-Wave antennas is crucial to the design success. What deserves attention is the substrates of low loss tangents (e.g., the liquid crystal polymer, LCP) should be employed for the FPCs carrying the mm-Wave antennas to achieve better mm-Wave radiation performance. In Fig. 3(b) [27], the exploded view of an FPC-based conformal integration of a 1 × 4 uniform mm-Wave antenna array (for band n261) and two virtual equivalent non-mm-Wave antennas (for band n79) fed by two non-mm-Wave sources is shown. The gray part is the flexible low-loss dielectric substrate, the yellow ones are metal, the green ones are the FR4 board and antenna carrier, and the blue ones represents the matching components.

D. EXTERIOR TYPE

Currently, for most mobile phones, inclusive of 5G ones, the metal exteriors, especially the metal frames, are the popular styles because the metal exteriors are not only the appealing features to customers but also the durable protection structures for mobile phones from being damaged easily. Therefore, for the handsets with (5G) mm-Wave wireless functions, the mm-Wave antennas generally have to co-exist with metal exteriors [28]–[30]. Additionally, it is very popular and mature to mobile phones to employ metal exteriors as non-mm-Wave antennas for LTE or 5G [31]–[33]; thus, the metal exteriors are quite natural to be the carriers for the integrations of mm-Wave and non-mm-Wave antennas to mobile phones. To overcome the shielding effect of the metal exteriors (on the PCB-type, module-type, and FPC-type antennas), to mitigate the antenna radome effect of dielectric superstrates over mm-wave antennas (as the filling or decoration parts for the on-metal antenna windows), and to reduce the internal occupied volumes by mm-Wave antennas, the mm-Wave antennas hence can be conformally relocated to the metal exteriors which function as non-mm-Wave antennas to accomplish the conformal integrated antenna designs. The integrated design called mm-Wave antennas in non-mm-Wave antennas (AiA) [28] based on the solution of antennas in metal exteriors (AiME) [28] was proposed in Fig. 4(a) accordingly. The uniformly-spaced mm-Wave antennas in Fig. 4(a) are in the type of stacked patches. The lower big patch is mainly for the low-band operation and the upper small one is primarily for the high-band performance. Moreover, two feeding points of each mm-Wave antenna element are set on two centerlines of orthogonal edges of the metal frame as an LTE antenna

FIGURE 3. (a) Mm-Wave and non-mm-Wave antennas integrated on an FPC [26]; (b) the exploded view of an FPC-based integration of mm-Wave and non-mm-Wave antennas [27].

FIGURE 4. (a) Mm-Wave antennas embedded in a metal frame of a mobile phone as an LTE antenna, i.e., the AiA design [28]; (b) exploded view of AiAiP solution [28].
upper small patch of the stacked patches to excite two polarizations, i.e., the vertical and horizontal ones (or the right-hand and left-hand circular ones). In terms of simulated 10-dB impedance bandwidths, the integrated mm-Wave antennas can cover 27.44−28.56 GHz and 36.92−40.22 GHz for the vertical polarization, and 27.32−28.56 GHz and 36.96−40.34 GHz for the horizontal polarization to both support the 3GPP 5G mm-Wave bands n261 and n260. To put it differently, the mm-Wave antennas are dual-band dual-polarized. Besides, in terms of simulated 6-dB impedance bandwidths, the non-mm-Wave antenna in the form of a metal frame covers 872−962 MHz and 2265−2740 MHz to accommodate LTE Band 8 (880−960 MHz), Band 40 (2300−2400 MHz), and Band 41 (2496−2690 MHz). The in-band isolation between mm-Wave and non-mm-Wave antennas is higher than 46.81 dB. Furthermore, further band isolation between mm-Wave and non-mm-Wave (2300−2400 MHz), and Band 41 (2496−2690 MHz). The in-band isolation between mm-Wave and non-mm-Wave antennas is higher than 46.81 dB. Furthermore, further derivatives of dual-polarized mm-Wave antennas integrated in metal exteriors also as non-mm-Wave antennas to cover more 3GPP 5G mm-Wave bands, such as bands n258, n257, n261, and n260 were studied as well [28]. Besides, to alleviate the feeding losses of the AiA design caused by the long feeding paths between mm-Wave antennas and mm-Wave RFIC(s), the upgraded solution named mm-Wave antennas in non-mm-Wave antennas integrating a package (AiAiP) [28] was innovatively presented in Fig. 4(b) to directly mount the AiP’s feeding package (including the IC(s), IC carrier board, IC shielding case, and connector) to the inside of the meal frame as a non-mm-Wave antenna in the AiA design.

E. HYBRID TYPE

As described above, due to the popular both existence of mm-Wave AiP modules and metal exteriors in mobile phones with mm-Wave wireless functions, the combinations of mm-Wave AiP modules and metal exteriors consequently make great sense as the hybrid-type integration solution for mm-Wave and non-mm-Wave antennas to mobile phones. Due to the shielding effect, the metal exteriors in nature are negative to mm-Wave antennas deployed inside the handsets. That’s the reason why mm-Wave antennas are relocated and embedded to metal exteriors as the AiME solution to avoid the shielding effect, or that’s why mm-Wave antennas should be elaborately placed with main radiation directions not blocked by metal exteriors. In the two mentioned ways, the mm-Wave antennas or mm-Wave AiP modules typically are not beneficial to metal exteriors no matter whether the metal exteriors serve as non-mm-Wave antennas or not; instead, the metal exteriors may benefit mm-Wave antennas as the antenna carriers, for examples, the ones in AiA designs, to accommodate the mm-Wave antennas. An interesting and innovative solution shown in Fig. 5 [34], on the contrary, was presented to employ a mm-Wave AiP module for supporting a non-mm-Wave antenna implemented by a metal frame through the in-between electrical connections to achieve a hybrid-type integration solution of mm-Wave and non-mm-Wave antennas. In Fig. 5, based on the referenced patent [34], the part 801a is the electrical path that operates as a legacy (i.e., non-mm-Wave) antenna, part 810a (part of 801a) is named the conductive side member which in fact can be understood as a metal frame, part 33-1 is the feeding point of the non-mm-Wave antenna, and part 160 is the 5G mm-Wave antenna module including the mm-Wave antenna arrays 161 wherein the part 161a is the patch antenna array and part 161b is the dipole antenna array. The metal frame 810a is electrically connected with the conductive region of the 5G mm-Wave antenna module 160. Through the hybrid-type integration solution combined from the mm-Wave antenna module and non-mm-Wave metal-exterior antenna, the device size is promising to get smaller with non-mm-Wave antenna performance (especially for the low bands, e.g., sub-1-GHz bands) secured or even strengthened because the length of the non-mm-Wave antenna can be innovatively elongated. In other words, now, the mm-Wave antenna module is part of and beneficial to the non-mm-wave antenna functioned by the metal exterior. In addition to this design, it’s also quite hopeful for further advanced and even more powerful hybrid solutions realized by the combinations of AiP, AiPiA, AiPaA, or AiPiA modules plus the discussed AiA designs or the AiAiP solution, i.e., the metal-exterior-based ones.

F. DISPLAY TYPE

Because of the higher and higher screen-to-body ratios (which thus significantly suppress the placement freedom and clearance areas for antennas) of mobile phones to upgrade visual experience of users, the innovative antenna-on-display (AoD) solution [35]−[38] was proposed to enable antennas compatible with displays. For the AoD solution, antennas are designed on displays (but under front cover glasses), for instance, in the form of imperceptible metal meshes so that the designed antennas are invisible to users. Moreover, through the AoD solution, lower possibility of blockage (by hands or metal) on the antennas in the main use scenarios, wider spatial coverage of beams, and good conformality to the displays can be attained as well. As shown in Fig. 6(a) [37], various separate antennas, including mm-Wave and non-mm-Wave ones, based on the AoD solution to a mobile phone are conceptually illustrated.
This article has been accepted for publication in a future issue of this journal, but has not been fully edited. Content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2022.3172321, IEEE Access

However, the shown mm-Wave and non-mm-Wave antennas are not integrated. Also, although the details or concepts of the integration designs of AoD-based mm-Wave and non-mm-Wave antennas haven't been published yet (to the best knowledge of the authors), it is quite reasonably promising to accomplish the display-type integration of mm-Wave and non-mm-Wave antennas by utilizing the common platforms, e.g., the imperceptible metal meshes laminated on the displays. Through the integrations of mm-Wave and non-mm-Wave antennas based on the AoD solution, total sizes of the integrated antennas can get smaller than the size sums of the separate AoD-based antennas, which can mitigate the negative impacts on the visual and touch experience (especially when the antennas are designed on the same metal meshes for touch panels) thanks to fewer grids needed to be broken on the metal meshes to form antennas. The above four discussed types (namely, the module type, FPC type, exterior type, and hybrid type) for integration solutions of mm-wave and non-mm-wave antennas to mobile phones are non-transparent to light and hence to sight. In comparison with the visually non-transparent (i.e., visible) types, the AoD solution is the visually transparent (i.e., invisible) type; as a result, the AoD solution is nicely beneficial for antennas (the intangible features to users) to co-exist with displays (the tangible features to users). Similarly, through the AoD solution, the functions and values of displays are also enhanced due to the empowered wireless communication capabilities.

III. EVOLUTION

As shown in Fig. 7, rather than follows the time sequence of the publication, the evolution of the above analyzed integration solutions of mm-Wave and non-mm-Wave antennas to mobile phones actually is inspiring depicted mainly based on the straightforwardness of the solution generation, that is, based on the easiness and rationality to trigger the thought extension, in the order from the reported to promising ones. The vertical axis shows primary advantages or the salient philosophy of the solutions; also, four horizontal axes are illustrated to represent the carriers, locations, (visual) transparency, and conformity of the mentioned solutions, respectively. As described in the subsection A of the Sec. II, because the PCBs are the fundamental and necessary platforms to past and current mobile phones, the antenna integration evolution thus naturally debuts from the PCB type with the PCBs reused as the solution carrier.

Nonetheless, the PCB-type antennas (and hence their integration) generally are not so practical to competitive mobile phones due to the typical needs of large clearance areas and of modifications (e.g., slots) on the system PCBs which carry lots of components and traces. The integration evolution thus transitions to the current mainstream type of mm-Wave antennas to mobile terminals, that is, the module type with the mm-Wave AiP modules as the solution carrier. To put it differently, it is quite reasonable to reuse the current mainstream solution to expand capabilities of conventional or presently commercialized mm-Wave AiP modules for covering non-mm-Wave bands by integrating physical or/and functioning as virtual equivalent non-mm-Wave antennas.

Additionally, due to the good maturity, wide applications, and decent conformity, the FPCs are very straightforward to be considered as the appealing carriers for the mm-Wave and non-mm-Wave antenna integrations accordingly.

Besides, due to the popularity of the metal exteriors of mobile phones, the prevailing applications of the metal exteriors as non-mm-Wave antennas for mobile phones, and the avoidance of metal shielding (on the PCB-type, module-type, and FPC-type), to integrate mm-Wave and non-mm-Wave antennas with the metal exteriors as the carrier to be the exterior-type solution for realizing metal compatibility therefore is the next progress.

Furthermore, in view of the prevalent both existence of the two parts (i.e., two resources), the mm-Wave AiP modules and metal exteriors in mobile phones with mm-Wave wireless functions, the interesting and inspiring integration to combine the two existing resources as the hybrid-type solution with both the mm-Wave AiP modules and metal exteriors as the solution carriers is thus presented so that the mm-Wave AiP modules can innovatively benefit the non-mm-Wave antennas in the form of metal exteriors. What’s more, likewise, based on the philosophy of resource combination, it is also hopeful and practical that FPC-type solution can be combined with the module-type solution, such as the AiP, AiPiA, AiPaA, or AiPiaA, or the exterior-type solution as well to trigger even more novel, more competitive, and more advanced new hybrid integration solutions of mm-wave and non-mm-wave antennas to mobile phones.
The described integration solutions of the module type, FPC type, exterior type, and hybrid type in principle are not placed to face users. By contrast, the innovative and promising display-type integration based on the AoD solution deploying invisible antennas on the displays (i.e., the solution carrier) to achieve the compatibility of displays, the salient and kernel features of current mobile phones, where the antennas can be located to face users for more creative applications (in addition to the mentioned cellular communications), e.g., the mm-wave radio detection and ranging (Radar) for gestures, faces, or motion recognition, emerges after the mentioned hybrid-type solution.

As for the solution locations, the PCB-type, module-type, and FPC-type solutions normally are inside mobile phones; the exterior-type solution is on the outsides of mobile phones. The hybrid-type solution is both inside and on outsides of mobile phones, and the display-type one is laminated between the front cover glass and the display (an exposed part). In other words, the solution locations move from inside to the exposed parts of the mobile phones.

Moreover, for the solution conformality, a very critical characteristic to mobile phones, the PCB type is planar and conformal to boards, basically not to the discussed curved and sleek shapes of mobile phones (for attractiveness and competitiveness reinforcement). For the module and hybrid types, currently, they are not conformal; generally, the FPC type is the best at conformality with the exterior and display types good at this.

In terms of visual transparency of solutions, the PCB-type, module-type, FPC-type, exterior-type, and hybrid-type ones typically are visually non-transparent; that is, visible and light blocking. The display-type solution, however, is invisible, i.e., visually transparent, to users so that the optical properties of the displays can be better ensured. To put it differently, the integration solutions progress from visual non-transparency to visual transparency.

What’s more, to prevent the blockage by hands, heads, and metal, multiple antennas, especially the mm-Wave antennas (and hence their integrations with non-mm-Wave antennas), typically are deployed at multiple locations (for a mobile phone) with the switching algorithm applied for antenna triggering to ensure wireless performance [39]–[41].
Last but not least, the red dashed frame in Fig. 7 stands for the fundamental and prime framework and the core goal, namely, miniaturized device sizes with satisfied antenna performance, for all the proposed and predicted integration solutions of mm-Wave and non-mm-Wave antennas to mobile phones.

VI. CONCLUSION
By integrating mm-Wave and non-mm-Wave antennas to mobile phones, in addition to securing the original functions, the precious synergy of reduction in total occupied volumes by the originally separate antennas can be also elegantly attained so that the product competitiveness can be well strengthened. The systematic and informative retrospective on the four reported integration solutions (the PCB type, module type, FPC type, exterior type, and hybrid type) and the enlightening and interesting prospect on the two promising solutions (the display type, and advanced new hybrid one) are both insightfully proposed from diverse and pragmatic perspectives. Future developments and researches on the attractive and critical topic can hence be greatly excited, benefited, and facilitated.

HUAN-CHU HUANG received the double B.S. degrees in power mechanical engineering and electrical engineering from National Tsing Hua University (NTHU), Hsin-Chu, Taiwan, in 2001, the M.S. degree in electronics engineering from National Chiao Tung University (NCTU), Hsin-Chu, Taiwan, in 2003, the M.B.A. degree in 2006 and the Ph.D. degree in communication engineering in 2015 both from National Taiwan University (NTU), Taipei, Taiwan.

Since 2005, he has been with several global leading smartphone companies, such as HTC (Taoyuan, Taiwan), Nokia (Beijing, China), Huawei (Shanghai, China), Apple (Shanghai, China), and Vivo (Dongguan, China), all in the area of antenna designs. To date, he has published 42 IEEE papers, held 80 international granted patent families, and co-authored three whitepapers for the wireless communication industry. Presently, he is the Senior Antenna Technical Expert and Antenna Team Leader at the Innovation Research Institute of Visionox Technology Co., Ltd., China. His current research interests mainly involve antenna designs for terminal devices.

JIAGUO LU was born in Lujiang, Anhui, China, the research fellow and doctoral supervisor serving in University of Science and Technology of China (USTC) and Anhui University. He has been Vice Chief Engineer and Vice President of East China Research Institute of Electronics Engineering, President of East China Research Institute of Microelectronics, Member of National High-tech R&D Program of China (863 Program), Expert of National Reconnaissance Early Warning System and Spacecraft Payload, Member of Radar Sub-council and Microwave Sub-council of China Institute of Electronics (CIE), and Vice Chair-person of Antenna Sub-council.

Lu has performed the research on microwave imaging radar and antenna technology for a long time. He has recognized and addressed the emerging issues in the development of high resolution, multi-polarization and multi-bands microwave imaging radar and active array antennas by means of microwave electro-magnetic fields, making systematic and creative contributions in imaging radar and antenna technology.

Lu has won one Second Prize of National Science & Technology Progress, and dozens of Special Prize, First Prize and Second Prize of National Defense Science & Technology Progress. He has authored three publications and more than 80 papers in core journals, holding more than 40 invention patents.
