Abstract. In this paper the exponential life time model is used as a competing risk model. The causes of failures are assumed independent. For analysis of the data Type-I progressive interval censoring is used. Point estimation and interval estimation of the parameters and survival function are made using maximum likelihood and bootstrap methods. Non-parametric estimation is also considered. A real life example is provided to illustrate the results obtained in the paper.

Keywords: Progressive Type-I, interval censoring, maximum likelihood, bootstrap, survival function, non-parametric.

1 Introduction

Nowadays the analysis of time to event data is of great importance in the fields of medicine, engineering etc. For example, time to death of patients, and life of electrical components under test. Sometimes failure of an item or individual may be due to more than one cause. For example, Boag[1] studied the case of a breast cancer patient, where the cause of death was recorded as “cancer” or “other”; Peck[2] stated that failure of transistors may be due to electrical degradation of certain parts or by faulty bounding of the leads. When the items or individuals fail the failure time and an indicator number corresponding to the specific cause of failure were recorded. Here we assume the causes of failure are independent.

Suppose that an item exhibits \( k \) modes (causes) of failures. When the item begins operation, each failure mode simultaneously generates a random life that is independent of the other modes. Thus, in effect, \( k \) life times are denoted by \( X_1, X_2, \ldots, X_k \) which simultaneously begin, where life time \( X_i \) corresponds to the \( i^{th} \) cause of failure, \( i = 1, 2, \ldots, k \); and failure of the item occurs, as soon as any one of the \( k \) life times, say \( X_i \) is realized. Hence the life length of the unit, denoted by the random variable \( X \) is nothing but

\[
X = \min \{X_1, X_2, \ldots, X_k\} = X_{(i)}
\]

and its cumulative distribution function (cdf) of \( X \), say \( F_X(x) \) is given by

\[
F_X(x) = 1 - \prod_{i=1}^{k} [F_{X_i}(x)]
\]

(1)

Such a model is called competing risk failure model and \( F_X(x) \) becomes its cdf.

This model is different than the mixture model. In mixture model only one of the \( k \) possible causes of failure generates a random life that causes part failures.

In practice, the attributes like electrical thermal, climate and mechanical stresses applied to an item may be observed as causes of failures of an item. Mendenhall and Hader[3], Patel and Gajjar[4], Boardman and Kendell[5], Patel[6], have considered progressive type I grouped (interval) censoring for various types of mixture and compound (competing risk) life time models.

2 Competing Risk Failure Model
Suppose that the device exhibits two modes of failures and each failure mode simultaneously generates a random life time $X_i$ and $X_j$ respectively i.e. $X_i$ is the time of failure of the device due to cause $i$ and the probability density function (pdf) of $X_i$ is given by

$$f_i(x) = \frac{1}{\theta} e^{-\frac{x}{\theta}}; \quad x > 0; \quad \theta > 0; \quad i = 1, 2$$

and the corresponding cdf is

$$F_i(x) = P(X_i \leq x) = 1 - e^{-\frac{x}{\theta}}; \quad i = 1, 2$$

Let $T$ be the time of failure of the device regardless of cause, then $T = \min(X_i, X_j)$. So pdf of $T$ will be

$$h_i(t) = \frac{1}{\theta} e^{-\frac{t}{\theta}}$$

and its cdf will be

$$H_i(t) = 1 - e^{-\frac{t}{\theta}}, \quad \text{where} \quad \frac{1}{\theta} = \frac{1}{\theta_1} + \frac{1}{\theta_2} \cdot$$

Hence the survival function of the model will be

$$f(t) = 1 - H_i(t) = e^{-\frac{t}{\theta}}$$

According to Boardman & Kendall[5] the competing risk failure model can be obtained as follow:

Let $g_i(t)$ be the probability that an item fails by cause $i$ and it does not fail by the cause $i' \neq i$ up to time $t$ with two independent causes only, then

$$g_i(t) = f_i(t) [1 - F_i(t)], \quad i' \neq i = 1, 2$$

Hence the pdf of $T$ can be obtained as

$$h_i(t) = c (g_i(t) + q_i(t))$$

$$= c \left[ f_i(t) [1 - F_i(t)] + f_j(t) [1 - F_j(t)] \right]$$

$$= c \frac{1}{\theta_1} e^{-\frac{t}{\theta_1}} + c \frac{1}{\theta_2} e^{-\frac{t}{\theta_2}}$$

where $c$ is a normalizing constant, here it will be 1. We call the failure model in (6) as the exponential competing risk failure model.

### 3 Interval Censoring

Interval censored data arise when observations are known to lie only in some interval between time points $a$ and $b$. Here experimental units are not monitored continuously. Such data may arise in a variety of circumstances but are commonly encountered in medical studies, where patients are only monitored at regular interval, e.g. weekly or quarterly check-up. In engineering such kind of censoring is known as group censoring. The generalization of such censoring scheme are progressive Type-I interval censoring or progressive Type-II interval censoring schemes. Several authors have considered such generalized censoring schemes in life testing experiments. Some of them are Patel & Patel[7], Shah & Patel[8], Patel and Gajjar[9], Arora, Bhimani and Patel[10]. Several authors have used such interval censoring scheme in clinical, medical, biomedical engineering studies like Odell et al[11], Samuelson and Kongerud[12], Rao[13], Aggarwala[14], etc. Recently Gajjar &Patel[15], Gadhvi and Bhimani[16], Patel & Patel[17], have considered Progressive Type-I group censoring for discrete (geometric) life time model. Patel and Gajjar[4] have considered maximum likelihood estimation for compound exponential life time model based on progressively Type-I grouped censored sample. They have assumed different parameter at each stage of censoring.
Here we consider the estimation for exponential competing risk failure model under progressive Type-I interval censoring keeping the same parameter (unchanged) at each stage of censoring. MLE and Confidence interval estimation is considered. Bootstrap methods are also used to derive the confidence intervals. Non-parametric method for estimating survival function is also considered. A real life example is used to exemplify the theory.

The setup of \( m \)-stage progressive Type-I censoring scheme is described as follows:

Let \( n \) units are put on life test at time zero and observations on each of these units is continued until the unit fails or is censored. Units are observed at pre-set times \( T_i, T_2, \ldots, T_m \), where \( m \) is a fixed integer. Thus the time axis is partitioned into mutually exclusive intervals \( \left[ 0, T_1 \right), \left[ T_1, T_2 \right), \ldots, \left[ T_{m-1}, T_m \right) \] and \( 0, T_1, T_2, \ldots, T_m \) where \( mT_m \) is the time when experimentation is scheduled to terminate.

Let \( x_i \) denote the number of units falling in \( I_i \) due to cause \( j \); \( j = 1, 2 \) and \( r_i \) be the set of live units removed at time \( T_i \); \( i = 1, 2, \ldots, m \) and \( r_m \) is equal to all the remaining units at time \( T_m \). The values \( r_1, r_2, \ldots, r_m \) may be pre-specified as positive integers or percentages \( p_1, p_2, \ldots, p_m \), with \( p_m = 100 \) of the remaining live units.

Then based on the observed data \( \{x_{i1}, x_{i2}, \ldots, x_{in}, x_{i2}, \ldots, x_{in} \} \) the joint likelihood function will be proportional to the following expression:

\[
L(\theta_1, \theta_2) \propto \prod_{i=1}^{m} \left[ G_1(T_i) - G_1(T_{i-1}) \right]^{x_i} \prod_{i=1}^{m} \left[ G_2(T_i) - G_2(T_{i-1}) \right]^{r_i} \prod_{i=1}^{m} \left[ 1 - H(T_i) \right] \tag{7}\]

with

\[
r_m = n - \sum_{i=1}^{m} x_i - \sum_{i=1}^{m} x_i - \sum_{i=1}^{m} r_i \tag{8}\]

Based on \( g_i(t) \), defined in (6), we define

\[
G_i(T) = P(X_i \leq T) = \int_0^T g_i(t) \, dt = \frac{1}{\theta_1} e^{-\frac{T}{\theta_1}} \tag{9}\]

and

\[
G_i(T) = P(X_i \leq T) = \int_0^T g_i(t) \, dt = \frac{1}{\theta_2} e^{-\frac{T}{\theta_2}} \tag{10}\]

Using (9) and (10) in (7), the likelihood function becomes

\[
L = L(\theta_1, \theta_2) \propto \prod_{i=1}^{m} \left[ \frac{\theta_1}{\theta_2} \right]^{x_i} \left[ e^{-\frac{T_i}{\theta_1}} - e^{-\frac{T_i}{\theta_2}} \right]^{x_i} \prod_{i=1}^{m} \left[ \frac{\theta_2}{\theta_1} \right]^{r_i} \left[ e^{-\frac{T_i}{\theta_2}} - e^{-\frac{T_i}{\theta_1}} \right]^{r_i} \prod_{i=1}^{m} \left[ 1 - e^{-\frac{T_i}{\theta_1}} \right]^{y_i} \tag{11}\]

where

\[
x_i = x_{i1} + x_{i2}, S_i = T_i - T_{i-1}, y = \sum_{i=1}^{m} T_{i-1} x_i + \sum_{i=1}^{m} T_{r_i} \tag{12}\]

To obtain maximum likelihood estimate of \( \theta_1 \) and \( \theta_2 \), we would like to maximize:

\[
\log L = -\sum_{i=1}^{m} x_i \log \left( \frac{1}{\theta_1} + \frac{1}{\theta_2} \right) - \sum_{i=1}^{m} x_i \log \theta_1 - \sum_{i=1}^{m} x_i \log \theta_2 - y \left( \frac{1}{\theta_1} + \frac{1}{\theta_2} \right) + \sum_{i=1}^{m} x_i \log \left[ 1 - e^{-\frac{S_i}{\theta_1}} \right] \tag{13}\]

Thus, the equations to be solved for the maximum likelihood estimate of \( \theta_1 \) and \( \theta_2 \) are

\[
\frac{\partial \log L}{\partial \theta_1} = \sum_{i=1}^{m} \frac{x_i}{\theta_1} \left( \frac{1}{\theta_1} + \frac{1}{\theta_2} \right) - \frac{\sum_{i=1}^{m} x_i}{\theta_1} - \frac{u}{\theta_2} - \frac{1}{\theta_1} \sum_{i=1}^{m} x_i \left( S_i e^{-\frac{S_i}{\theta_2}} \right) \tag{14}\]
and
\[
\frac{\partial \log L}{\partial \theta_2} = \sum_{i=1}^{m} \frac{x_i}{\theta_2^2} - \frac{y}{\theta_2} - \frac{1}{\theta_2} \sum_{i=1}^{m} \left[ x_i S_i e^{-\frac{1}{\theta_1} \left( \frac{1}{\theta_2} \right)} \right] = 0
\]  
\tag{15}

From (14) and (15), we get
\[\theta_2 = \frac{\sum_{i=1}^{m} x_{2i}}{\sum_{i=1}^{m} x_i} \]  
\tag{16}

Again from (14) we can write,
\[\sum_{i=1}^{m} \left( \frac{x_i \theta_2}{\theta_1 + \theta_2} \right) + y - \sum_{i=1}^{m} \left[ x_i S_i e^{-\frac{1}{\theta_1} \left( \frac{1}{\theta_2} \right)} \right] \]
\[\theta_1 = \frac{\sum_{i=1}^{m} x_i}{\sum_{i=1}^{m} x_i} \]  
\tag{17}

Substituting \(\theta_2\) from (16) in (17) we get the right hand side (17) as a function of parameter \(\theta_1\) only. Thus, using (16) \& (17) we can write:
\[\theta_1 = \varphi(\theta_1) = \text{ a function of } \theta_1 \]  
\tag{18}

Solving the equation (18), by any method of iteration we get MLE of \(\theta_1\) say \(\hat{\theta}_1\), and substituting it in equation (16), we will get MLE of \(\theta_2\) say \(\hat{\theta}_2\).

The MLE of survival function at time \(t_0\) is given by
\[\hat{S}(t_0) = e^{-\frac{1}{\hat{\theta}_1} \left( \frac{1}{\hat{\theta}_2} \right)} \]  
\tag{19}

4 Standard Error of the Estimators

The asymptotic variances and covariance of the MLE of the parameters \(\theta_1\) and \(\theta_2\) can be obtained from the elements of the inverse of the Fisher information matrix (I) given by:
\[I^{-1} = \begin{bmatrix}
-E \left( \frac{\partial^2 \log L}{\partial \theta_1^2} \right) & -E \left( \frac{\partial^2 \log L}{\partial \theta_1 \partial \theta_2} \right) \\
-E \left( \frac{\partial^2 \log L}{\partial \theta_1 \partial \theta_2} \right) & -E \left( \frac{\partial^2 \log L}{\partial \theta_2^2} \right)
\end{bmatrix}
\]
\[= \begin{bmatrix}
V(\hat{\theta}_1) & \text{cov}(\hat{\theta}_1, \hat{\theta}_2) \\
\text{cov}(\hat{\theta}_1, \hat{\theta}_2) & V(\hat{\theta}_2)
\end{bmatrix}
\]

The exact mathematical expressions for the above expectations are difficult to obtain, therefore, we calculate observed asymptotic variance-covariance for the MLE by dropping the expectation ‘E’.
\[\begin{bmatrix}
V(\hat{\theta}_1) & \text{cov}(\hat{\theta}_1, \hat{\theta}_2) \\
\text{cov}(\hat{\theta}_1, \hat{\theta}_2) & V(\hat{\theta}_2)
\end{bmatrix} = \begin{bmatrix}
-\frac{\partial^2 \log L}{\partial \theta_1^2} & -\frac{\partial^2 \log L}{\partial \theta_1 \partial \theta_2} \\
-\frac{\partial^2 \log L}{\partial \theta_1 \partial \theta_2} & -\frac{\partial^2 \log L}{\partial \theta_2^2}
\end{bmatrix}(\hat{\theta}_1, \hat{\theta}_2) \]  
\tag{20}

where
competing risk failure model. The main steps of the algorithm are given below:

On the basis of the algorithm given in Aggarwal [14] for simulating a sample under progressive censoring, the asymptotic variance of survival function can be obtained from the equation

\[ V\left(S\left(t_{ni}\right)\right) = \left(\frac{\partial S}{\partial \theta_1}\right)^2 V(\hat{\theta}_1) + \left(\frac{\partial S}{\partial \theta_2}\right)^2 V(\hat{\theta}_2) + 2\frac{\partial S}{\partial \theta_1} \frac{\partial S}{\partial \theta_2} \text{cov}(\hat{\theta}_1, \hat{\theta}_2) \]

Hence the asymptotic variance of survival function can be obtained from the equation

\[ V\left(S\left(t_{ni}\right)\right) = \left(\frac{\partial S}{\partial \theta_1}\right)^2 V(\hat{\theta}_1) + \left(\frac{\partial S}{\partial \theta_2}\right)^2 V(\hat{\theta}_2) + 2\frac{\partial S}{\partial \theta_1} \frac{\partial S}{\partial \theta_2} \text{cov}(\hat{\theta}_1, \hat{\theta}_2) \]

5 Simulation Algorithm

A study of properties of maximum likelihood estimators based on progressively Type-I interval censored samples involves simulation. A short algorithm for simulating a random sample of size \( n \) put on a life test at time 0 is given below. Here we use the following properties of the progressive interval censoring

\[ X_{1i} \sim B\left(n, G_1\left(T_1\right)\right) \quad \text{and} \quad X_{ni} = B\left(n, G_i\left(T_i\right)\right) \]

where \( G_1\left(T_1\right) \) and \( G_i\left(T_i\right) \) are defined in (9) and (10) respectively and for \( i = 2, 3, \ldots, m \)

\[ X_{j} / X_{j-1}, X_{j-2}, X_{j-3}, \ldots, X_{1i}, R_{1i}, \ldots, R_{j} \sim B\left(n - \sum_{i=1}^{j-1} \left(X_{1i} + X_{2i} + \cdots + X_{j-1i} + R_{j-1i}\right), \frac{G_j\left(T_j\right) - G_j\left(T_{j-1}\right)}{1 - G_j\left(T_{j-1}\right)} \right) \]

\[ = B\left(n - \sum_{i=1}^{j-1} \left(X_{1i} + X_{2i} + \cdots + X_{j-1i} + R_{j-1i}\right), \frac{G_j\left(T_j\right) - G_j\left(T_{j-1}\right)}{1 - G_j\left(T_{j-1}\right)} \right) \quad : \quad j = 1, 2 \]

Here \( B\left(n, p\right) \) denotes the binomial distribution with parameters \( n \) and \( p ; \quad 0 < p < 1 \).

On the basis of the algorithm given in Aggarwala [14] for simulating a sample under progressive Type-I interval censoring scheme, Gadhvi and Bhimani [16] have modified the simulation scheme for competing risk failure model. The main steps of the algorithm are given below:
Algorithm 1.

1: Set \( i = 0, X_{1\text{sum}} = 0, X_{2\text{sum}} = 0, R_{\text{sum}} = 0 \)
2: Next \( i \)
3: If \( i = m + 1 \), exit the algorithm.
4: Generate \( X_{1i} \) and \( X_{2i} \) as binomial random variables with parameters \( (n, G_{1}(T_{i})) \) and \( (n, G_{2}(T_{i})) \) respectively.
5: Generate \( X_{1i} \) and \( X_{2i} \) as binomial random variables with parameter \( \left( n - X_{1\text{sum}} - X_{2\text{sum}} - R_{\text{sum}}, 1 - G_{1}(T_{i}) \right) \) and \( \left( n - X_{1\text{sum}} - X_{2\text{sum}} - R_{\text{sum}}, 1 - G_{2}(T_{i}) \right) \) respectively.
6: Calculate \( \left( \frac{1}{2} \right) \text{Floor} \left[ \frac{p_{i} \left( n - X_{1\text{sum}} - X_{2\text{sum}} - R_{\text{sum}} + X_{i} \right)}{\min(R_{1}, n - X_{1\text{sum}} - X_{2\text{sum}} - R_{\text{sum}} - X_{i})} \right] \) or \( \min(R_{1}, n - X_{1\text{sum}} - X_{2\text{sum}} - R_{\text{sum}} - X_{i}) \)
7: Set \( X_{1\text{sum}} = X_{1\text{sum}} + X_{1i}, X_{2\text{sum}} = X_{2\text{sum}} + X_{2i}, R_{\text{sum}} = R_{\text{sum}} + R_{i} \)

This algorithm generates \( m \) binomial random variables. Here either the values \( p_{1}, p_{2}, \ldots, p_{m-1} \) or proposed values of \( R_{1}, R_{2}, \ldots, R_{m} \) are fixed in advance by the experimenter. Here \( p_{m} = 1 \) and \( R_{m} = n - \sum_{1}^{m} X_{1i} - \sum_{i}^{m} X_{2i} - \sum_{1}^{m-1} R_{i} \).

6 Confidence Interval Estimation

A. Asymptotic Confidence Interval

Using the asymptotic normality property of maximum likelihood estimator, confidence interval for MLE can be obtained for parameters \( \theta_{1}, \theta_{2} \) and for survival function \( S(t_{0}) \) as follows:

\((1- \alpha)100\% \) asymptotic confidence interval for \( \hat{\theta}_{i} \) becomes

\[ \hat{\theta}_{i} \pm Z_{\alpha/2} \sqrt{V(\hat{\theta}_{i})}, i = 1, 2 \]

and for \( S(t_{0}) \):

\[ \hat{S}(t_{0}) \pm Z_{\alpha/2} \sqrt{V(\hat{S}(t_{0}))} \]

where \( V(\hat{\theta}_{i}) \) and \( V(\hat{S}(t_{0})) \) can be obtained from equations (20) & (24) and \( Z_{\alpha/2} \) is \( \left( \frac{\alpha}{2} \right)^{\text{th}} \) percentile of standard normal distribution.

B. Bootstrap Confidence Interval

B-I: Percentile Bootstrap Method
Algorithm 2.
1: From the original data $X$ compute the ML estimates of the parameters say $\hat{\theta}_1$ and $\hat{\theta}_2$ from (18) and (16).
2: Use $\hat{\theta}_1$ and $\hat{\theta}_2$ to generate a bootstrap sample $X^*$ with the same values of $T_i$, $r_i$ and $m$, $i = 1, 2, ..., m$ using the algorithm given in section 5.
3: As discussed in step 1, based on $X^*$ compute the bootstrap sample estimator of $\theta_1$, $\theta_2$ and $S(t_j)$, say $\hat{\theta}_1^*$, $\hat{\theta}_2^*$ and $\hat{S}^*(t_j)$.
4: Repeat steps 2 and 3, $S$ times representing $S$ bootstrap MLE’s of $(\theta_1, \theta_2, S(t_j))$ based on $S$ different bootstrap samples.
5: Arrange all $\hat{\theta}_1^*$, $\hat{\theta}_2^*$ and $\hat{S}^*(t_j)$ in an ascending order to obtain bootstrap sample $(\phi^{[1]}, \phi^{[2]}, ..., \phi^{[s]})$, $l = 1, 2, 3$ where $\phi_1 = \hat{\theta}_1^*$, $\phi_2 = \hat{\theta}_2^*$ and $\phi_l = \hat{S}^*(t_j)$.
6: Let $G(Z) = P(\phi \leq Z)$ be the cumulative distribution function of $\phi$. Define $\phi_{\text{boot}} = G^{-1}(Z)$ for given $Z$. The approximate bootstrap $100(1 - \alpha)$% confidence interval of $\phi_l$ is given by
$$\left[\phi_{\text{boot}}\left(\frac{\alpha}{2}\right), \phi_{\text{boot}}\left(1 - \frac{\alpha}{2}\right)\right].$$

B-II. Bootstrap-t Method

Algorithm 3.
1: From the original data $x$ compute the MLE of the parameters say, $\hat{\theta}_1, \hat{\theta}_2$ and $\hat{S}(t_j)$.
2: Use $\hat{\theta}_1$ and $\hat{\theta}_2$ to generate bootstrap sample $X^*$ with the same values of $T_i$, $r_i$ and $m$, $i = 1, 2, ..., m$ using the algorithm given in B-I.
3: Based on $X^*$ compute the bootstrap sample estimates of $\theta_1$, $\theta_2$ and $S(t_j)$, say $\hat{\theta}_1^*$, $\hat{\theta}_2^*$ and $\hat{S}^*(t_j)$.
4: Compute the following statistics:
$$T_1^* = \frac{\sqrt{n}(|\hat{\theta}_1^* - \hat{\theta}_1|)}{\sqrt{V(\hat{\theta}_1)}}, T_2^* = \frac{\sqrt{n}(|\hat{\theta}_2^* - \hat{\theta}_2|)}{\sqrt{V(\hat{\theta}_2)}}, T_3^* = \frac{\sqrt{n}(|\hat{S}^*(t_j) - \hat{S}(t_j)|)}{\sqrt{V(\hat{S}(t_j))}}.$$
5: Repeat steps 3 and 4 $S$ (boot) times.
6: From the values of $T_i^*, i = 1, 2, 3$ obtained in step 4, determine the upper and lower bounds of the $100(1 - \alpha)$% confidence interval of the parameters and survival function as follows:
Let $H(x) = P(T_i^* \leq x)$, $i = 1, 2, 3$ be the cdf of $T_i^*$. For a given $x$ define $(\hat{\theta}_{\text{Boot-1}}\left(\frac{\alpha}{2}\right), \hat{\theta}_{\text{Boot-1}}\left(1 - \frac{\alpha}{2}\right))$. Similarly we can define other parameters.
7 Non-Parametric Estimation of Survival Function

Kaplan Meier estimate of survival function \( S(t_i) \) can be obtained according to Miller et al\[18\]. Its estimate and the estimate of the variance can be obtained as follow:

\[
\hat{S}(t_i) = \prod_{j \leq i} \left( \frac{n - i}{n - i + 1} \right)
\]  

and

\[
\text{Asy} \hat{V}(\hat{S}(t_i)) = \hat{S}^2(t_i) \sum_{j \leq i} \frac{\delta_j}{(n - i)(n - i + 1)}
\]

Using the results (7.1) & (7.2), the \((1- \alpha)100\%\) asymptotic confidence interval for \( \hat{S}(t_i) \) can be obtained

\[
\hat{S}(t_i) \pm Z_{\alpha/2} \sqrt{\text{Asy} \hat{V}(\hat{S}(t_i))}
\]

8 Application

The data about the failure time of radio transceivers considered by Mendenhall and Hader\[3\] is given below. Failures are classified as one of the two types: those confirmed on arrival at the maintenance centre (Type-I) and those unconfirmed (Type-II). The data consist of a failure time (in hours) and type for each failure until when observations cease after 600 hours. We have modified the data considering the withdrawals at the end of each failure time interval.

| Number | Time interval | Type – I Failures: | Type – II Failures: | Withdrawals |
|--------|---------------|-------------------|-------------------|-------------|
|        | (T_{i-1}, T_i) | x_{1i} | x_{0i} | R_{i} |
| 1      | 0-50          | 26    | 15    | 3    |
| 2      | 50-100        | 27    | 14    | 2    |
| 3      | 100-150       | 28    | 20    | 0    |
| 4      | 150-200       | 35    | 13    | 0    |
| 5      | 200-250       | 17    | 11    | 0    |
| 6      | 250-300       | 20    | 8     | 1    |
| 7      | 300-350       | 10    | 7     | 1    |
| 8      | 350-400       | 11    | 5     | 1    |
| 9      | 400-450       | 11    | 3     | 0    |
| 10     | 450-500       | 7     | 4     | 0    |
| 11     | 500-550       | 6     | 1     | 0    |
| 12     | 550-600       | 9     | 2     | 51   |

As per our notations we have \( S_i = T_i - T_{i-1} = 50, m =12, T_m = 600, T_0 = 0, n = 369, r_m = 51. \)

Solving the equations (16) to (17) of section 3 we find MLEs of \( \theta_1 \) and \( \theta_2 \) as

\[
\hat{\theta}_1 = 468.568470 \quad \text{and} \quad \hat{\theta}_2 = 941.686148
\]

From (3.13) we get MLE for survival function at time \( t_0 = 150 \) as

\[
\hat{S}(t_0 = 150) = 0.619147
\]

Using (20) the asymptotic variance –covariance matrix of the MLEs for parameter \( \theta_1 \) and \( \theta_2 \) is given by

\[
\begin{pmatrix}
V(\hat{\theta}_1) & \text{Cov}(\hat{\theta}_1, \hat{\theta}_2) \\
\text{Cov}(\hat{\theta}_1, \hat{\theta}_2) & V(\hat{\theta}_2)
\end{pmatrix} =
\begin{pmatrix}
228.490456 & 64.098690 \\
64.098690 & 1854.391245
\end{pmatrix}
\]
Hence the asymptotic standard errors of the MLEs of the parameters will be
\[ SE(\hat{\theta}_1) = 15.115901 \quad \text{and} \quad SE(\hat{\theta}_2) = 43.062643 \]

Hence from (24) we get
\[ SE\left( \hat{S}(t_0 = 150) \right) = 0.008179. \]

To apply bootstrap confidence interval estimation for the parameters we have made 1000 simulations based on the MLEs of \( \hat{\theta}_1 \) and \( \hat{\theta}_2 \) given in (28) with the other values fixed as follows:

\[ S_i = T_i - T_{i-1} = 50, \quad m = 12, \quad T_m = 600, \quad T_0 = 0, \quad n = 369 \]

of the given real life data.

The summary statistics for our simulation are given in the following table:

| Parameter | min | 0.025 | 0.25 | 0.50 | 0.75 | 0.975 | max |
|-----------|-----|-------|------|------|------|-------|-----|
| \( \hat{\theta}_1 \) | 453.881921 | 534.49941 | 600.519587 | 635.009587 | 666.823853 | 738.014578 | 815.657104 |
| \( \hat{\theta}_2 \) | 1103.24111 | 1196.47891 | 1380.32981 | 1490.57503 | 1605.86791 | 1888.97570 | 2276.43244 |
| \( \hat{S}(t_0) \) | 0.460287 | 0.674061 | 0.701207 | 0.714147 | 0.723910 | 0.744047 | 0.763701 |
| \( T\hat{\theta}_1 \) | -19.556925 | 70.818664 | 123.872344 | 146.354047 | 163.912440 | 195.743508 | 216.159550 |
| \( T\hat{\theta}_2 \) | 58.444155 | 83.146751 | 118.733825 | 134.023486 | 146.362393 | 166.596258 | 177.334380 |
| \( T\hat{S}(t_0) \) | 50.028425 | 136.05393 | 213.647116 | 252.157978 | 283.773046 | 349.591892 | 427.982516 |

Based on the simulation results the confidence interval based on MLE and the bootstrap confidence intervals for parameters and the survival function are computed using the methods described in Section 6, which are given in the following table:

| Method | Parameter | Estimate | Confidence Interval | Length of the Interval |
|--------|-----------|----------|---------------------|------------------------|
| MLE    | \( \theta_1 \) | 634.857929 | (591.910652, 677.805205) | 85.894553 |
|        | \( \theta_2 \) | 1502.724540 | (1345.933796, 1659.515285) | 313.581489 |
|        | \( S(t_0 = 150) \) | 0.712668 | (0.698474, 0.726863) | 0.028389 |
| Percentile Bootstrap | \( \theta_1 \) | 634.857929 | (534.499419, 738.014578) | 203.515159 |
|        | \( S(t_0 = 150) \) | 0.712668 | (0.694061, 0.744047) | 0.069986 |
| Bootstrap - t  | \( \theta_1 \) | 634.857929 | (524.295848, 622.599502) | 98.303654 |
|        | \( S(t_0 = 150) \) | 0.712668 | (0.677079, 0.768004) | 0.090925 |

The following tables give estimate of the survival (Reliability) function \( S(t_0) \) of an item at time \( t_0 \). Its asymptotic variance and asymptotic 95% confidence interval of \( S(t_0) \) based on MLE and nonparametric estimation are calculated as discussed in sections 6 and 7.
Table 3. Estimate of survival (Reliability) function ($\hat{S}(t_0)$), with its asymptotic variance and asymptotic confidence interval calculated using MLE

| $t_0$ | $\hat{S}(t_0)$ | AsyV($\hat{S}(t_0)$) | 95% Confidence interval for $\hat{S}(t_0)$ | Length of CI |
|-------|----------------|------------------------|---------------------------------------------|--------------|
|       |                |                        | Lower limit                                  | Upper limit  |
| 50    | 0.852311       | 1.408663E-05           | 0.84954                                     | 0.859667     | 0.014713 |
| 100   | 0.726433       | 4.093199E-05           | 0.713894                                    | 0.739873     | 0.025079 |
| 150   | 0.619147       | 6.609232E-05           | 0.603115                                    | 0.635178     | 0.032063 |
| 200   | 0.527705       | 8.400141E-05           | 0.509486                                    | 0.545924     | 0.036438 |
| 250   | 0.449769       | 9.806867E-05           | 0.430359                                    | 0.469179     | 0.038822 |
| 300   | 0.383343       | 0.000103               | 0.363491                                    | 0.403195     | 0.039704 |
| 350   | 0.326727       | 0.000101               | 0.306987                                    | 0.346467     | 0.039480 |
| 400   | 0.278473       | 9.624045E-05           | 0.259245                                    | 0.297701     | 0.038456 |
| 450   | 0.237345       | 8.848273E-05           | 0.218909                                    | 0.255782     | 0.036873 |
| 500   | 0.202292       | 7.35409E-05            | 0.184832                                    | 0.219752     | 0.034920 |
| 550   | 0.172416       | 6.97510E-05            | 0.156046                                    | 0.188785     | 0.032739 |
| 600   | 0.146952       | 6.30084E-05            | 0.131732                                    | 0.162171     | 0.030439 |

Here we see that up to 450 hours asymptotic variance of the estimate of survival function and length of confidence interval based on MLE are smaller than that based on non-parametric estimation.

Table 4. Estimate of survival (Reliability) function ($\hat{S}(t_0)$), with its asymptotic variance and asymptotic confidence interval calculated using nonparametric estimation

| $t_0$ | $\hat{S}(t_0)$ | AsyV($\hat{S}(t_0)$) | 95% Confidence interval for $\hat{S}(t_0)$ | Length of CI |
|-------|----------------|------------------------|---------------------------------------------|--------------|
|       |                |                        | Lower limit                                  | Upper limit  |
| 50    | 0.888889       | 0.000268               | 0.856823                                    | 0.920955     | 0.064132 |
| 100   | 0.776752       | 0.000268               | 0.744665                                    | 0.808839     | 0.066174 |
