Abstract | This study was planned to investigate the proximate composition, quality indices, amino acids, fatty acids, volatile aromatic compounds and minerals content of blue swimmer crab meat. Blue crab (Callinectes sapidus) samples (average weight was 140.13±0.13g) were obtained from Baltim fish market, Kafar Elshalik, Egypt during July, (2019). Blue crab meat samples were stored -18°C for 12 hrs. They were washed with tap water, manually dis-carapaces, then meat obtained was rewash carefully and drained. The obtained results showed that the major constituents (wt.%) of raw crab meat were 83.59% moisture, 9.12% crude protein, 1.80% lipid, 1.22% ash and 4.27% carbohydrates content. In addition, values of quality criteria of carp flesh were 7.35 pH, 47.42 mg/100g total volatile basic nitrogen (TVB-N), 0.19 mg/100g trimethylamine nitrogen (TMA-N) and 0.15 mg Malonaldehyed/kg sample thioarbarbitric acid (TBA). Also, crab meat contained 19 volatile aromatics compounds, 8 essential amino acids (EAA), 9 nonessential amino acids (NEAA), 8 saturated fatty acids (SFAs) and 7 unsaturated fatty acids (USFAS). In addition, it contained high levels of Na, K, Ca and Mg. In general, this study confirms that blue crab meat is an important source of valuable nutrients AAS, FAs and major elements.

Keywords | Blue crab, Quality indices, Nutritive value

INTRODUCTION

Seafood is an important source of valuable nutrients, like minerals (e.g. calcium, iron, zinc, iodine, selenium, copper), vitamins, fatty acids (e.g. long chain n-3 polyunsaturated fatty acids) and high quality proteins with essential amino acids, and is low in saturated fats (Nesheim and Yaktine, 2007). Some species of crabs are edible and number of others is commercially important for fishmeal industry. The crabs are increasingly realized as a potential food source for their delicacy and nutritional richness (Ravichandran et al., 2012). Moisture, crude protein, lipid and ash content were ranged from 53.56 to 89.4%, 8.02 to 15.7%, 0.23 to 0.97% and 0.35 to 6.22%, respectively as reported by Elegbede and Fashina-Bombata (2008); Marques et al. (2010); Özden and Erkan (2011); Varadharajan and Soundarapandian (2014);Silambarasan et al. (2016); Premarathna et al. (2015) and Yogesh Kumar et al. (2019). While pH, TVB-N and TBA values were ranged from 6.16 to 8.50; 7.85 to 19.29 mg/100g and 0.25 to 0.38 MDA/kg sample, respectively as found by Ibrahim, (2010); Bello, (2013); Shimaa et al. (2014) and AbouZeed (2016). Also, total EAA and NAA were 121.29 and 241.99 mg\100g, respectively as reported by Chen et al. (2013); Fulton and Elizabeth (2014); Kathirvel et al. (2014); Lu et al. (2014); Silambarasan et al. (2016) and Moruf and Lawal-Are (2019). While values of Oleic (c18:1), Linoleic (c18:2) and Stearic (c18:0) were 35.28, 57.71 and 40.23 mg\100g, respectively. As well as total aldehydes, aromatics, N-containing compounds, ketones and hydrocarbon compounds values were 1637.67, 140.36, 489.41, ND and 45.49, respectively of male chinese mitten crab (Eriocheir...
sinensis) as reported by Gu et al. (2013). And also, Sodium, Potassium, Calcium, Magnesium and Zinc content were 102.8, 136.4, 216.8, 79.5 and 9.84 mg/100g, respectively as reported by Silambarsan et al. (2016). In Egypt, total production of crab during 2017 was estimated about 5859 tons (3.21% of total catch 1.822.800 tons) as reported by the Generally Authority of Fish Resources Development (GAFRD, 2017). Therefore, this work aims to determine the biochemical analysis of raw blue crab meat.

MATERIALS AND METHODS

CRAB SAMPLES

About 25 kg of raw blue crab (Callinectes sapidus Rathbun, 1896) samples were purchased from Baltim Fish Market, Kafar Elshaikh, Egypt during July, 2019. The blue crab was transported immediately using ice box within 5 hours to Fish Processing and Technology Laboratory, Elqanater Elkhairia Fish Research Station, National Institute of Oceanography and Fisheries. The average weight (Mean ± SD) of blue crab was 140.13±0.13g. Crab samples were stored -18°C for 12 hrs, to remove their carapaces easily. They were washed with tap water, dis-carapaces and viscera were manually removed. Crab flesh were carefully rewashed, drained with plastic net and analyzed.

ANALYTICAL METHODS

CHEMICAL COMPOSITION

Chemical composition of crab meat; moisture content of crab meat by a drying oven, at 105°C for overnight, total crude protein (total N×6.25) by Kjeldahl apparatus, total crude fat by Soxhlet apparatus using petroleum ether, and ash content by a muffle furnace at 550°c till obtained a constant weight were determined according (AOAC, 2005).

QUALITY INDICES

pH VALUE

The pH values of raw crab meat were measured were estimated by pH meter (Orion pH meter Model 420 A) as the method described by Zaika et al. (1976).

TOTAL VOLATILE BASES-NITROGEN (TVB-N) CONTENT

TVB-N content was estimated by macro-distillation method of Person (1976) was determined as follows: Sample of 20-25mg was placed in glass hydrolysis tube containing 10 ml of 6 N HCl with 0.1% mercaptoethanol. The tube was sealed and heated in an oven at 110 °C for 24 hrs. The hydrolyzed sample was then cooled to room temperature and filtered through Whatman No. 1 filter paper. The tube and precipitate on the paper was washed with distilled water and the filtrates were then completed to a 25ml in a volumetric flask. Five ml of the filtrate were transferred to a 25ml beaker and placed under vacuum in a desiccator over Potassium hydroxide (KOH). The resulted dried residue was dissolved in one ml of sodium citrate buffer of pH 2.2 and stored at 4°C until analyzed by Beckman Amino Acid Analyzer Model 119 CL. The results obtained were expressed as g/100g sample (on dry wt. basis). This determination was done at amino acids Lab., Agricultural Research Center, Cairo, Egypt.

DETERMINATION OF FATTY ACIDS

The method of (AOAC, 2000) was conducted for lipid extraction from sample using chloroform methanol (2:1 v/v). The lipid samples were saponified over-night with
ethanoic KOH (20%) at room temperature (Vogel, 1975). In order to have more representative samples, lipid extracts from crab samples were pooled together for preparation of fatty acid methyl esters (FAME) and two such pooled samples were analyzed. The lipids were trans methylated using ethanoic Koh (20%) at room temperature to obtain FAME. FAME was analyzed by (a Pye Unicam series 304 Gas Chromatography) for identifying the individual fatty acids. The separation of fatty acid methyl esters was conducted using a coiled glass column (1.5m×4 mm) packed with Diatomite (100-20 mesh) and coated with 10% polyethylene glycol adipate (PEGA). The column oven temperature was programmed at 8 °C/min from 70°C to 190°C, then isothermally at 190°C for 25 min with nitrogen at 30 ml/min (Farag et al., 1986).

**Volatile aromatic compounds**

Volatile aromatic compounds were determination by Gas chromatography according to the methods described by Gu et al. (2013). Analytical of volatile compounds was performed by using a Perkin Elmer Auto system XL equipped with flame ionization detector (FID). A fused silica capillary column ZB5 (60m x 0.32 i.d.) was used. The oven temperature was maintained initially at 50°C to 240°C at a rate of 30°C/min. Helium was used as the carrier gas, at flow rate 1.1ml/min. The injector and detector temperatures were 230 and 250°C, respectively. This determination was done at Flavors, Taste and Smell Lab., National Research Center, Cairo, Egypt.

**Minerals composition**

Minerals composition; Na, K, Ca, ph, Fe, Mg, Mn and Zn were determined according to the methods described by Walsh (1955) using an atomic absorption spectrophotometer (ICE 3000 SERIES, England). 1g of oven-dried crab sample was put in combustion degree oven 500°C for two days. The samples were digested with 3 ml concentrated nitric acid and 1 ml of perchloric acid. The mixture was placed on a water bath till a clear colour was obtained. So the sample is ready to estimate the concentration of the elements steps measurements device. This determination was done at Central Lab., Faculty Agriculture, Zagzig University.

**Statistical analysis**

The results obtained were subjected to descriptive statistics and tested using analysis of variance and Duncan's multiple range tests using SPSS version 20 Statistical Package for Windows (Differences were considered to be significant when p<0.05).

**RESULTS AND DISCUSSION**

Table 1 shows the proximate analysis and quality criteria of raw blue crab flesh. The chemical composition (ww) of crab meat was 83.59% moisture, 9.12% crude protein, 1.80% lipid, 1.22% ash and 4.27% carbohydrates content. Our results are lower content of crude protein, lipid and ash than 18.53%, 3.27%, 5.74%, respectively of crab (Chironomantes boulengeri) (Khaled and Khafaji, 2018) and 15.30%, 2.30%, 5.70%, respectively of crab (Atergatis rosea) (Salama and Mona, 2018). However, moisture was higher content than (73.50 – 76.40%) those findings by the same authors. Concerning carbohydrates, it is lowest content than 2.70% of estuarine crab (Scylla serrata) (Jelin and Keerthika, 2017) and also 2.10% of swimming crab (Charybdis smithii) (Yogesh et al., 2019).

| Item                     | Value (%)          |
|--------------------------|--------------------|
| Moisture                 | 83.59±0.16        |
| Protein                  | 9.12±072           |
| Lipid                    | 1.80±076           |
| Ash                      | 1.22±081           |
| Carbohydrate             | 4.27±005           |
| pH value                 | 7.35±006           |
| TVB-N (mg/100 g)         | 47.42±9.69         |
| TMA-N (mg/100 g)         | 0.19±001           |
| TBA (mg MA/kg sample)    | 0.15±036           |

(VTVB: total volatile basic nitrogen; TMA-N: trimethylamin nitrogen; TBA: thiobarbituric acid.)

This variation in chemical composition of crab is affected by season and location of catch, feeding, crab species, age, sex etc. (Barrento et al., 2010). With regard to quality indices of crab meat (Table 1), values of pH, TVB-N, TMA-N and TBA of crab flesh were 7.35, 47.42 mg/100g, 0.19mg/100g and 0.15mgMDA/kg sample, respectively. The pH value was higher than 6.60 (Mehta and Nayak, 2017), 6.16 (AbouZeed, 2016) and 8.50 (Ibrahim, 2017) of some different crustaceans species. Also, the TVB-N content was higher than 4.06 and 4.86 mg/100g of crayfish and shrimp, respectively (Ibrahim, 2017). TBA content was lower than 0.63 and 0.79 mg/100g of crayfish and shrimp, respectively (Ibrahim, 2017). Also, the TBA content was lower than 0.25 MDA/kg sample (Shimaa et al., 2014). Our data showed that TVB value was high compared with previous studies, may be refer to handling steps of crab from catch to marketing.

**Amino acids composition of raw blue crab meat**

Amino acids composition (DW) of raw blue crab meat is presented in Table 2. It could be found that total essential amino acids (EAAs) composition of raw blue crab meat was 21.8mg/sample and included 7 AAs. The values of EAAs were threonine 2.92, valine 2.94, methionine 1.86,
Table 2: Essential (EAAs) and Nonessential (NEAAs) amino acids of crab meat (DW).

| EAAs          | mg/100g | NEAAs          | mg/100g |
|---------------|---------|----------------|---------|
| Threonine     | 2.92    | Serine         | 2.39    |
| Valine        | 2.94    | Glutamic       | 9.96    |
| Methionine    | 1.86    | Glycine        | 4.58    |
| Leucine       | 4.71    | Aspartic       | 5.75    |
| Phenylalanine | 2.69    | arginine       | 6.18    |
| Histidine     | 1.55    | Proline        | 3.04    |
| Lysin         | 5.13    | Alanine        | 4.76    |
|               |         | Tyrosine       | 2.50    |
|               |         | Cysteine       | 0.98    |
| Total EAAs    | 21.8    | Total non-EAAs | 40.14   |

EAA: Essential amino acids; NEAA: Nonessential amino acids.

In this study, total EAAs of blue crab meat was higher than 2.657 mg/100g (Silambarasan et al., 2016) and also 5.56 mg/100g (Wilson et al., 2017). However, total content is lower than 22.34 mg/100g (El-Gendy et al., 2018) and also 34.70 mg/100g (Moruf and Lawal-Are, 2019). Moreover, total nonessential amino acids (NEAAs) composition of crab meat was 40.41 mg/100g sample and involved 9 AAs. The values of NEAAs were serine 2.39, glutamic 9.96, glycine 4.58, aspartic 5.75, arginine 6.18, proline 3.04, alanine 4.76, tyrosine 2.50 and cysteine 0.98 mg/100g.

Our results are higher than 3.705 mg/100g for only 7 NEAAs of rainbow crab (Silambarasan et al., 2016) and 5.92 mg/100g of swimming crab (Wilson et al., 2017) however, they are lower content than 19.98 mg/100g of green tiger prawn (Penaeus Semisulcatus) (El-Gendy et al., 2018) and 26.15 mg/100g of crab (Callinectes amnicola) (Moruf and Lawal-Are, 2019) for only glutamic, aspartic and cysteine.

Fatty acids composition of raw blue crab meat

Data in Table 3 show the saturated (SFAs) and unsaturated (UFAs) fatty acids of raw blue crab meat. Total SFAs of crab meat was 2733.67 mg/100g sample, included 8 FAs. Values of SFs were stearic 2354.63, arachidic 46.28, pelargonic 91.66, heneicosanoic 3.63, lignoceric 174.47 and behenic 63.00 mg/100g while both Undecylic and tridecylic were not detected. On the other side, total USFAs was 1061.93 mg/100g, included also 8 FAs. Values of USFs were nondecylic 274.41, eicosenoic 8.82, nervonic 319.50, oleic 56.69, linolenic 24.60, Linoleic 196.79, eicosadienoic 179.90 and tricosanoic 1.22 mg/100g of crab meat.

Volatile aromatics compounds of blue crab meat

Figure 1 and Table 4 and show that 23 components of volatile aromatic compounds (ww) of raw blue crab meat were determined and identified. These compounds could be divided into 7 groups.
Compounds were 34.91, 0.15, 0.06, 0.03, 29.76, 34.75 and 0.05, respectively. The groups compounds were taken the following order; aldehydes, ketones, N-containing compounds. These results are within several authors; Giogios et al. (2013) and Gu et al. (2013) who found that the values of total volatile aromatic compounds ranged 0.45-1637.67 aldehydes, 0.29-140.36 aromatics and not detected-45.49 hydrocarbon, respectively of shrimp (Parapenaeus longirostris) and male Chinese mitten crab (Eriocheir sinensis).

Table 4: Volatile compounds of blue crab meat.

| Compound          | Relative area (%) |
|-------------------|-------------------|
| **Aldehydes**     |                   |

*ND: not detected.

Table 5: Minerals of crab meat.

| Element          | mg/100g |
|------------------|---------|
| Sodium           | 1.98    |
| Potassium        | 1.23    |
| Calcium          | 0.29    |
| Magnesium        | 0.22    |
| Phosphorous      | 0.44    |
| Zinc             | 0.01    |

**CONCLUSION**

Based on the results obtained, total volatile basic nitrogen (TVB-N) of crab meat was a high content but it does not exceed the permissible level of crustaceans. Crab meat contained 19 volatile aromatics compounds, 7 essential amino acids (EAAs), 9 nonessential amino acids (NAAs), 8 saturated fatty acids (SFAs) and 7 unsaturated fatty acids (USFAs). Also, total SFAs (was higher than total USFAs). In addition, it contained accepted levels of Na, K, P, Ca and Mg. Generally, this study recommends that blue crab meat is an important source of valuable nutrients, AAS, FAs and major elements.
