This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Recombinant protein (EGFP-Protein G) coated PbS quantum dots for *in vitro* and *in vivo* dual fluorescence (visible and second-NIR) imaging of breast tumors

Akira Sasaki\(^{a,b}\), Yoshikazu Tsukasaki\(^{c}\), Akihito Komatsu\(^{z}\), Takao Sakata\(^{d}\), Hidehiro Yasuda\(^{e}\) and Takashi Jin\(^{a,b,f}\)

We report a one-step synthetic strategy for the preparation of recombinant protein (EGFP-Protein G) coated PbS quantum dots for dual (visible and second-NIR) fluorescence imaging of breast tumors at the cellular and whole-body level.

Non-invasive whole-body imaging using near-infrared (NIR) fluorescence has been broadly developed because of its low tissue absorption and scattering compared to that observed with visible fluorescence.\(^1\)–\(^3\) Recently, second-NIR fluorescence (1000–1500 nm) has been used for non-invasive *in vivo* imaging.\(^4\)–\(^6\) Second-NIR fluorescence imaging has advantages over traditional NIR fluorescence imaging (700–900 nm) such as reduced light scattering and minimal autofluorescence.\(^7\) For the second-NIR fluorescence imaging, semiconductor quantum dots (QDs) such as PbS,\(^8\)–\(^13\) PbSe,\(^10\) and Ag\(_2\)S\(^14\) are promising fluorescent probes because of their strong fluorescence and photostability at wavelengths in the range of 1000–1500 nm. However, fluorescence imaging using second-NIR QDs usually encounters two major difficulties. First, the preparation of the QD-based fluorescent probe needs multiple synthetic steps such as QD formation, surface modification and biomolecule conjugation.\(^8\)–\(^14\) Second, the fluorescence detectors of conventional microscope systems do not support second-NIR fluorescence imaging.\(^5\)–\(^7\) To overcome these problems, we have developed a dual (visible and second-NIR) emission QD probe that can be used for both cellular and non-invasive whole-body imaging. In this communication, we report a facile synthesis of recombinant protein functionalized PbS QDs with dual emission (visible and second-NIR fluorescence), which have a binding ability for antibody molecules (IgG) in aqueous solution.

We have used an enhanced green fluorescent protein (EGFP)-Protein G B1 domain\(^17\) tagged with glutathione S-transferase (GST) as a template\(^18,19\) (GST-EGFP-GB1, see ESI) to grow PbS QDs in aqueous phase (Scheme 1). The recombinant protein, GST-EGFP-GB1 was genetically designed and prepared by a conventional method for recombinant protein synthesis in *Escherichia coli*. Protein G is a cell surface protein of *Streptococcus* and its B1 domain binds to the Fc region of immunoglobulin G (IgG). It has been widely used for detecting and

**Scheme 1** A schematic representation of the synthesis of recombinant protein (GST-EGFP-GB1)-coated PbS QDs. GST-EGFP-GB1 protein is used as a template for growing PbS QDs in aqueous phase. Antibody molecules bind to the Protein G B1 domain on the QD by simply mixing the antibody with the QD solution.
purifying IgG antibodies.\textsuperscript{17} Especially in cancer molecular imaging, a receptor-targeting antibody can act as a powerful tool via the conjugation of antibodies to the QD surface. In this case, a large amount of antibody is used for conjugation to QDs.\textsuperscript{2,11,13} Since the GST-EGFP-GB1-coated QDs contain a Protein G B1 domain, they can easily bind to antibody molecules by the simple mixing of antibodies with QD solution.\textsuperscript{20-22} The fluorescent protein EGFP is chosen to add a function of visible fluorescence emission to the second-NIR emitting PbS QDs. This dual-emitting property of the QDs enables a conduction of high-resolution cellular confocal imaging by EGFP fluorescence in addition to the deep-tissue imaging by second-NIR fluorescence. Thus the GST-EGFP-GB1-coated QDs make it possible to correlate the intracellular localization of probes with bio-distribution in the whole mouse body.

GST-EGFP-GB1-coated PbS QDs can be prepared by using a protein-mediated QD synthetic method (Scheme 1).\textsuperscript{18,19} The synthesis is carried out by reacting GST-EGFP-GB1 with lead acetate (Pb(Ac)_2) at ambient conditions to promote the binding of Pb\textsuperscript{2+} to GST-EGFP-GB1 (see, experimental section in ESI). The addition of an aqueous solution of sodium sulfide (NaS) immediately forms PbS QDs coated with the GST-EGFP-GB1 protein. By this synthetic method, we can easily prepare protein-coated PbS QDs within 10 minutes. To characterize the GST-EGFP-GB1-coated PbS QDs, we have measured their transmission electron microscopic (TEM) images, dynamic light scattering (DLS), and fluorescence/absorption spectra. Fig. 1a shows TEM images of GST-EGFP-GB1-coated PbS QDs. The PbS QDs have spherical shapes (ca. 5 nm) with a selected area diffraction (SAED) pattern and lattice fringes, confirming the crystalline nature of the PbS QDs with a cubic structure.\textsuperscript{23} Hydrodynamic size of the PbS QDs was determined to be ca. 30 nm in diameter by DLS (Fig. 1b). This value is ca. 20 nm larger than that determined by TEM analysis. This indicates that the GST-EGFP-GB1 fusion proteins (10 nm in diameter) surround the surface of the PbS QDs. Fluorescence spectrum of the GST-EGFP-GB1-coated PbS QDs showed dual emission, with visible emission at 515 nm and a second-NIR emission at 1150 nm, under excitation at 450 nm (Fig. 1c and Figs. S1, S2 in ESI). The visible and NIR fluorescence emissions are from EGFP proteins and PbS QDs, respectively. The quantum yield (QY) of the second-NIR fluorescence of PbS QDs (1150 nm emission peak) was measured by a relative method with CdSeTe/CdS QDs (840 nm emission, QY = 50\%) as a standard (see, experimental section in ESI). The value of QY was determined to be 10\% in water.

The binding ability of GST-EGFP-GB1-coated QDs towards antibody was confirmed using a fluorescence correlation spectroscopy (FCS).\textsuperscript{23-25} Fig. 2 shows fluorescence autocorrelation curves for the GST-EGFP-GB1 protein, GST-EGFP-GB1-coated QD, and the mixture of anti-HER2 antibody + GST-EGFP-GB1-coated QDs. Fluorescence autocorrelation curves are fitted according to the one-component diffusion model,\textsuperscript{23,24} allowing spherical shape assumption for all three samples. Binding between the Protein G B1 domain and the antibody was confirmed by the change in the diffusion time of the GST-EGFP-GB1-coated QDs (0.82 ms) and the mixture of anti-HER2 antibody + GST-EGFP-GB1-coated QDs (1.26 ms). Based on the Einstein-Stokes equation, hydrodynamic diameters were estimated to be 23 nm for GST-EGFP-GB1-coated QDs and 35 nm for the complex of anti-HER2 antibody + GST-EGFP-GB1-coated QDs. This result confirms the binding of anti-HER2 antibody to the GST-EGFP-GB1-coated QDs. It is also confirmed by the analysis of the photon counts per particle (CPP), expressing the fluorescence brightness of the single-particle. The CPP value of the GST-EGFP-GB1-coated QDs is two times higher than that of the free GST-EGFP-GB1 protein (Inset of Fig. 2), indicating that at least two GST-EGFP-GB1 molecules are included in one PbS QD. It should also be noted that the CPP value of the mixture of anti-HER2 antibody + GST-EGFP-GB1-coated QDs is four times higher than that of the free GST-EGFP-GB1 protein. This indicates that the complex of antibody + QDs contain two GST-EGFP-GB1-coated QDs due to the inter-particle binding of the GB1 domain by their respective QDs.

Fig. 1 (a) TEM image of protein (GST-EGFP-GB1)-coated PbS QDs (scale bar: 10 nm). The inset shows the SAED pattern of the QDs. The right image shows a high-resolution TEM image of the PbS QDs (scale bar: 5 nm). (b) Distributions of the hydrodynamic diameter of free GST-EGFP-GB1 protein and the QDs measured by DLS. (c) Fluorescence and absorption spectra of protein-coated QDs with emission peaks at 515 nm (EGFP) and 1150 nm (QD).
To demonstrate the capability of GST-EGFP-GB1-coated QDs, we first performed the fluorescence imaging of breast tumor cells in the visible and second-NIR regions. For fluorescence imaging, we have used a human breast tumor cell line (KPL-4) overexpressing HER2 on its cell membrane. Fig. 3a shows a high-resolution confocal fluorescence image (excitation: 473 nm, emission: 515 nm, at 60x magnification) of KPL-4 cells stained with anti-HER2 antibody and GST-EGFP-GB1-coated QDs. Green fluorescence of the EGFP is clearly observed on the cell surface, indicating that GST-EGFP-GB1-coated QDs bind to the HER2 receptors via anti-HER2 antibody on the KPL-4 cell surface (Fig. 3a and Fig. S3 in ESI). For the second-NIR fluorescence imaging, we have used a home-built wide-field dissecting microscope equipped with an InGaAs detector (see experimental section in ESI). Fig. 3b shows a second-NIR fluorescence image of KPL-4 cells stained with anti-HER2 antibody and GST-EGFP-GB1-coated QDs. Second-NIR fluorescence (excitation: 670 nm, emission: 1300 nm, 6.3x magnification) is clearly observed after a 30 min incubation of KPL-4 cells with anti-HER2 antibody and GST-EGFP-GB1-coated QDs (Fig. 3b). Each bright spot represents a single-cell. These results show that the GST-EGFP-GB1-coated QDs act as a dual-emission molecular targeting probe with visible and second-NIR fluorescence. GST-EGFP-GB1-coated QDs showed low cytotoxicity in HeLa cells at the concentration (≥250 nM) used for in vitro and in vivo fluorescence imaging (Fig. S4 in ESI).

Next, we performed a second-NIR fluorescence imaging of the breast tumor implanted KPL-4 cells in a nude mouse. An aqueous solution (200 μL) of GST-EGFP-GB1-coated QDs (1 μM) mixed with anti-HER2 antibody was injected into the tail vein, and second-NIR fluorescence images (excitation: 670 nm, emission: 1300 nm) of a live mouse were taken after 48 hours of the QD injection (Fig. 4). As shown in Fig. 4c, intense second-NIR fluorescence from the breast tumor is clearly observed, compared to the control without QD injection (Fig. S5 in ESI). This indicates the accumulation of anti-HER2 antibody binding QDs in the tumor. In contrast, there is no significant second-NIR fluorescence in the area without tumors (Fig. 4b). To confirm actual accumulation of the QDs in the breast tumor cells, we carried out ex vivo fluorescence imaging of an isolated tumor at a higher magnification by the confocal microscope and the second-NIR microscope (Figs. 4d, 4e, and Fig. S6 in ESI). Compared with the negative control without QDs injection (Fig. 4d), intense fluorescence of EGFP emitting from the anti-HER2 antibody-conjugated QDs was observed in the breast tumor (Fig. 4e). This finding indicates that the conjugates of anti-HER2 antibody and GST-EGFP-GB1-coated QDs pass through the blood vessels of the breast tumor and bind to the HER2 receptors on the tumor cells.

In summary, we have demonstrated a one-step facile method for preparing GST-EGFP-GB1 protein-coated PbS QDs with a dual emission of visible (515 nm) and second-NIR fluorescence (1150 nm). PbS QDs have two molecules of GST-EGFP-GB1 protein per QD particle, and they can easily bind IgG antibodies via their GB1 domain. We demonstrate that the GST-EGFP-GB1-coated PbS QDs have a dual-color probe capability for the fluorescence molecular imaging of breast tumors at the cellular and whole-body level. An important feature of this work is that the GST-EGFP-GB1-coated QDs make it possible to correlate the cellular distribution of QD probes with their bio-distribution in the whole body. These dual emission PbS QDs with antibody binding ability can be extended to a variety of in vitro and in vivo tumor imaging techniques by constructing conjugates between specific antibodies for tumors and the GST-EGFP-GB1 protein-coated PbS QDs.
