BEING CAYLEY AUTOMATIC IS CLOSED UNDER TAKING WREATH PRODUCT WITH VIRTUALLY CYCLIC GROUPS

DMITRY BERDINSKY\textsuperscript{A,B}, MURRAY ELDER, AND JENNIFER TABACK

Abstract. We extend work of the first author and Khoussainov to show that being Cayley automatic is closed under taking the restricted wreath product with a virtually infinite cyclic group. This adds to the list of known examples of Cayley automatic groups.

1. INTRODUCTION

Cayley automatic groups, introduced by Kharlampovich, Khoussainov and Miasnikov in \cite{7}, generalise the class of automatic groups while retaining some key algorithmic properties. Namely, the word problem in a Cayley automatic group is decidable in quadratic time, and the first order theory for a (directed, labeled) Cayley graph of a Cayley automatic group is decidable. The family of Cayley automatic groups is larger than that of automatic groups, for example it includes all finitely generated nilpotent groups of nilpotency class two \cite{7}, the Baumslag-Solitar groups \cite{1, 7}, the higher rank lamplighter groups \cite{3}, and restricted wreath products of the form $G \wr \mathbb{Z}$ where $G$ is Cayley automatic \cite{2}.

Here we add to this list by extending \cite{2} to restricted wreath products of the form $G \wr H$ where $G$ is Cayley automatic and $H$ is virtually infinite cyclic. While this result is not surprising, the proof contains some subtleties which require care, and we believe is worth recording.

2. AUTOMATIC AND CAYLEY AUTOMATIC GROUPS

We assume that the reader is familiar with the notions of regular languages, finite automata and multi-tape synchronous automata. For more details, we refer the reader to \cite{6}. We say a language $L \subseteq (X^*)^n$ is regular if it is accepted by a synchronous $n$-tape automaton where $n \in \mathbb{N}$ and $X$ is a finite set, or alphabet.

For any group $G$ with finite symmetric generating set $S = S^{-1}$, let $\pi: S^* \to G$ denote the canonical projection map. For $w \in S^*$ let $|w|_S$ denote the length of $w$ as a word in the free monoid $S^*$, that is, $|w|_S$ denotes the number of letters in the word $w$.

Definition 2.1. An automatic structure for a group $G$ is a pair $(S, L)$ where

1. $S$ is a finite symmetric generating set for $G$;
2. $L \subseteq S^*$ is a regular language;
3. $\pi|_L: L \to G$ is a bijection;
4. for each $a \in S$ the binary relation $R_a = \{(u, v) \in L \times L \mid \pi(u)a =_G \pi(v)\} \subseteq S^* \times S^*$ is regular, that is, recognised by a two-tape synchronous automaton.

A group is called automatic if it has an automatic structure with respect to some finite generating set.

The third author acknowledges support from Simons Foundation grant 31736 to Bowdoin College.
It is a standard result, see, for example [8, Theorem 2.4.1], that if \( G \) is automatic then \( G \) has an automatic structure with respect to any finite generating set.

Cayley automatic groups were introduced in [7] with the motivation of allowing the language \( L \) of normal forms representing group elements to be defined over an arbitrary alphabet \( \Lambda \) rather than a generating set \( S \) for \( G \).

**Definition 2.2.** A Cayley automatic structure for a group \( G \) is a 4-tuple \((S, \Lambda, L, \psi)\) where

1. \( S \) is a finite symmetric generating set for \( G \);
2. \( \Lambda \) is an alphabet and \( L \subseteq \Lambda^* \) is a regular language;
3. \( \psi : L \to G \) is a bijection;
4. for each \( a \in S \) the binary relation
   \[
   R_a = \{ (u, v) \in L \times L \mid \psi(u)a =_G \psi(v) \} \subseteq \Lambda^* \times \Lambda^*
   \]
   is regular, that is, recognised by a two-tape synchronous automaton.

A group is called Cayley automatic if it has a Cayley automatic structure \((S, \Lambda, L, \psi)\) with respect to some finite generating set \( S \).

As for automatic groups, if \( G \) has a Cayley automatic structure \((S, \Lambda, L, \psi)\) and \( Y \) is another finite generating set for \( G \), then there exists a Cayley automatic structure \((Y, \Lambda_Y, L_Y, \psi_Y)\) for \( G \). See [7, Theorem 6.9] for a proof of this fact.

3. Wreath products with virtually infinite cyclic groups

For two groups \( G \) and \( H \), let \( G^H \) be the set of all functions \( \gamma : H \to G \) with finite support, that is, such that \( \gamma(h) \neq 1_G \) for at most finitely many \( h \in H \). For a given \( \gamma \in G^H \) and \( h \in H \), we denote by \( \gamma^h \) the element of \( G^H \) for which \( \gamma^h(x) = \gamma(hx) \) for all \( x \in H \). The restricted wreath product \( G \wr H \) can be defined as the Cartesian product \( G^H \times H \) with the group multiplication given by the formula:

\[
(\gamma, h) \cdot (\gamma', h') = (\gamma(\gamma')^{-1}, hh').
\]

Equivalently, we can define \( G \wr H \) as

\[
\left\{ (\gamma, h) \mid h \in H, \gamma \in \bigoplus_{k \in H} (G)_k \text{ where } \gamma \text{ has finitely many nontrivial entries} \right\}
\]

with multiplication defined as above, where

\[
(\gamma')^{-1} = \left( \bigoplus_{k \in H} (g)_k \right)^{-1} = \bigoplus_{k \in H} (g)^{-1}_k.
\]

Note that if \( G \) is generated by \( S_0 \subseteq G \) and \( H \) is generated by \( T \subseteq H \) then \( G \wr H \) is generated by \( S_0 \cup T \).

We prove the following theorem.

**Theorem 3.1** (Wreath products with virtually infinite cyclic groups). Let \( G \) be a Cayley automatic group, and \( H \) any virtually infinite cyclic group. Then \( G \wr H \) is Cayley automatic.

**Proof.** Since \( G \) is Cayley automatic, there exists a finite symmetric generating set \( S_0 \) for \( G \), an alphabet \( \Lambda_0 \), a regular language \( L_0 \subseteq \Lambda_0^* \), a bijection \( \psi_0 : L_0 \to G \), and a 2-tape automaton \( M \) for each \( s \in S_0 \) with accepted language

\[
L(M_s) = \{ (u, v) \in L_0 \times L_0 \mid \psi_0(v) =_G \psi_0(u)s \}.
\]

Without loss of generality assume \( \psi_0(\varepsilon) = 1_G \).

Let \( H \) be a finite extension of its cyclic subgroup \( \mathbb{Z} = \langle t \rangle \) of index \( m + 1 \), and denote by \( \langle t \rangle x_0, \langle t \rangle x_1, \ldots, \langle t \rangle x_m \) the distinct right cosets of \( \mathbb{Z} \), where \( x_0 = 1_H \). Let

\[
T = \{ t, x_1, \ldots, x_m, t^{-1}, x_1^{-1}, \ldots, x_m^{-1} \}.
\]
then \( S = S_0 \cup T \) is a symmetric generating set for \( G \wr H \). We identify a particular spanning tree \( S \) of the Cayley graph \( \Gamma(H,T) \) which consists of a “spine” corresponding to \( (t) \), and at each vertex \( t^k \) there are \( m \) “spokes” terminating at the \( m \) vertices \( t^k x_j \) of \( H \), for \( k \in \mathbb{Z} \) and \( 1 \leq j \leq m \), as in Figure 1.

![Figure 1](image_url)

**Figure 1.** Part of a spanning tree \( S \) for \( \Gamma(H,T) \), where the index of \( \mathbb{Z} = (t) \) in \( H \) is 5.

As a concrete example, consider the infinite dihedral group

\[ H = D_\infty = \langle a, b \mid a^2, b^2 \rangle \]

In this case we can take \( t = ab, x_1 = a \) and \( S = \Gamma(D_\infty, T) \), as shown in Figure 2.

![Figure 2](image_url)

**Figure 2.** Part of the spanning tree \( S \) (shown in black) drawn inside \( \Gamma(D_\infty, T) \), where \( T = \{t, a, t^{-1}, a^{-1}\} \). Note \( a = a^{-1} \) and \( ata = aaba = ba = t^{-1} \).

We borrow some terminology from the lamplighter groups \( \mathbb{Z}_m \wr \mathbb{Z} \) to describe elements of \( G \wr H \). An element \( v \in G \wr H \) can be thought of in two equivalent ways:

1. algebraically, as an element \((\gamma, h)\) where \( \gamma \in \bigoplus_{k \in H} (G)_k \) has finitely many nontrivial entries and \( h \in H \).
2. geometrically, as a copy of \( S \) (or \( \Gamma(H,T) \)) where each vertex is marked by some element of \( G \), with all but finitely many vertices marked by \( 1_G \), and the vertex \( h \) of \( S \) is also marked with a pointer indicating the final position of the “lamplighter”. We refer to this marking as a configuration of \( S \).

Write \( v = (\gamma, h) \) where \( \gamma \in \bigoplus_{h_i \in H} (G)_{h_i} \) and \( h \in H \). Since every element \( h \) of \( H \) can be written uniquely as \( h = t^k x_q \) for some \( k \in \mathbb{Z} \) and \( 0 \leq q \leq m \), the map \( \xi : H \to \mathbb{Z} \) defined by \( \xi(t^k x_q) = k \) is well defined. Then the vertex corresponding to \( h \in H \) is an endpoint of a spoke attached to the vertex \( t^{\xi(h)} \). For \( v = (\gamma, h) \) with \( \gamma \) as above, let

1. \( k_* = \xi(h) \),
2. \( k_1 = \min \{0, \xi(h_i) \mid (g)_{h_i} \in \gamma, (g)_{h_i} \neq 1_G \} \), and
3. \( k_2 = \max \{0, \xi(h_i) \mid (g)_{h_i} \in \gamma, (g)_{h_i} \neq 1_G \} \).

Additionally, let \( m_1 = \min(k_*, k_1) \) and \( m_2 = \max(k_*, k_2) \). Define the integer support of \( v \), denoted \( \text{isupp}(v) \), to be the interval \([m_1, m_2]\). The left endpoint of the integer support is the smallest \( k \) so that either

1. \( v \) has a nontrivial entry among the copies of \( \Gamma(G, S_0) \) attached to the spine at the vertex \( t^i x_i \) for some \( 0 \leq i \leq m \),
2. the final position of the lamplighter is \( t^i x_i \) for some \( 0 \leq i \leq m \), or
3. all of \( k_* \) and \( \xi(h_i) \) are positive, that is, the lamplighter is never in a position along the spine with negative index, so \( m_1 = 0 \) denotes the starting position of the lamplighter.

The right endpoint of the integer support is defined analogously, where the 0 is included in the definition of \( k_2 \) to account for the possibility that \( k_* \) and all the \( \xi(h_i) \) are negative.
To define our normal form, we mimic the standard “left-first” representation of elements of the lamplighter group \( \mathbb{Z}_n \wr \mathbb{Z} \) (cf. [4]). Given \( v = (\gamma, h) \in G \wr H \), we describe a path traversed by the lamplighter from the vertex \( 1_H \) in \( S \) to its final vertex \( h \in S \). If \( m_1 < 0 \), the lamplighter first moves left along the spine of \( S \) to the vertex labeled \( t^{m_1} \), and marks it with a possibly trivial element of \( G \). The lamplighter then visits \( t^{m_1} x_1 \) and marks it with a possibly trivial element of \( G \) and returns to \( t^{m_1} \). This procedure is repeated for the vertices \( t^{m_1} x_2, \ldots, t^{m_1} x_m \). The lamplighter then proceeds to the vertex corresponding to \( t^{m_1+1} \) and repeats the process of visiting the vertex at the end of each spoke in order and marking it with a possibly trivial element of \( G \). This continues until the lamplighter reaches the vertex corresponding to \( t^{m_2} \), where the process is repeated one last time. If \( m_1 = 0 \), the lamplighter begins the process of marking the vertices with possibly trivial elements of \( G \) at \( 1_H \in S \), and then visits the spokes as described above, until it reaches the vertex labeled \( t^{m_2} \) and marks the vertices \( t^{m_2} x_j \) for \( 0 \leq j \leq m \) with possibly trivial elements of \( G \).

We refer to the subpath which starts at the vertex \( t^{m_1} \) and ends at the vertex \( t^{m_2} \) after having marked the vertices \( t^i x_j \) for \( m_1 \leq i \leq m_2, 0 \leq j \leq m \) with possibly trivial elements of \( G \) as the positive path, because when written as a word in the group generators, the exponents of \( t \) are defined so that these are unique positions along the positive path.

Figure 3. The element \( t^{-2} x_2 g_1 x_2^{-1} x_4 g_2 x_4^{-1} t^3 g_3 x_1 g_4 x_1^{-1} t^{-2} x_3 \) as a configuration of \( S \). The integer support of this configuration is \([-2, 1]\) and the red arrow denotes the final position of the lamplighter. The positive path for this element is \( x_1 x_1^{-1} x_2 g_1 x_2^{-1} x_3 x_3^{-1} x_4 g_2 x_4^{-1} (tx_1 x_1^{-1} x_2 x_2^{-1} x_3 x_3^{-1} x_4 x_4^{-1})^2 t g_3 x_1 g_4 x_1^{-1} x_2 x_2^{-1} x_3 x_3^{-1} x_4 x_4^{-1} \) is shown in green.

Upon completing the positive path, one of two things will occur. It may be that the lamplighter is in its final position, and the path simply ends. If not, the lamplighter moves to its final position via a subpath of the form \( t^k \) or \( t^k x_q \) where \( k \in \mathbb{Z}, k \leq 0 \). Note that since \( m_2 \), the right endpoint of \( \text{isupp}(v) \), is the maximum of \( k_2 \) and \( k_s \), the lamplighter will never be in a position along \( \mathbb{Z} = \langle t \rangle \) to the right of \( m_2 \), so the exponent \( k \) is non-positive.

As the lamplighter travels along its positive path, we will wish to indicate two special positions: the first time the lamplighter is at the vertex corresponding to \( 1_H = t^0 \), and the first time the lamplighter is at the vertex which will be its final position. The integer support and the positive path are defined so that these are unique positions along the positive path.

The normal form for the Cayley automatic structure on \( G \wr H \) will be constructed in stages. We define a normal form \( N_0 \subseteq (A_0 \cup T)^* \) for elements of \( G \wr H \) as follows. Given \( v \in G \wr H \) with \( \text{isupp}(v) = [m_1, m_2] \), the above description allows us to uniquely represent \( v \) as a word either of the form

\[
(1) \quad v = t^n x_q \quad \text{or} \quad v = t^{m_1} v_1 t v_2 \cdots t v_s t^j x_q
\]

where \( n, j, q, s \in \mathbb{Z}, j \leq 0, s \geq 0, 0 \leq q \leq m, m_1 + (s - 1) = m_2 \) and

\[
(2) \quad v_i = v_{i,0} x_1 v_{i,1} x_1^{-1} x_2 v_{i,2} \cdots x_{m-1} v_{i,m} x_{m-1} x_m v_{i,m} x_m^{-1}
\]

with \( v_{i,t} \in L_0 \). If \( m_1 = k_s \) then we allow \( v_1 \) to be trivial, otherwise \( v_1 \) must be nontrivial. If \( m_2 = k_s \) we allow \( v_s \) to be trivial, otherwise \( v_s \) must be nontrivial. Each word \( v_i \) encodes a sequence of words \( (v_{i,0}, \ldots, v_{i,m}) \) in \( L_0^{m+1} \) with \( \psi_0(v_{i,0}) \) labeling the vertex at position \( t^{m_1+i} x_i \) in \( S \) and \( \psi_0(v_{i,m}) \) labeling the end of the spoke at position \( t^{m_1+i} x_i \) for \( 1 \leq i \leq m \). Note that in
Equation (1), the $v_i$ are separated by instances of $t$ as the lamplighter moves along the positive path. Let $N_0 \subseteq (\Lambda_0 \cup T)^*$ denote the set of words of this form.

For example, the element in Figure 3 has $N_0$ normal form

$$t^{-2}x_1^{-1}x_2v_1,2x_2^{-1}x_3x_3^{-1}x_4v_1,4x_4^{-1}tx_1^{-1}x_2x_2^{-1}x_3x_3^{-1}x_4x_4^{-1}tx_1^{-1}x_2x_2^{-1}x_3x_3^{-1}x_4x_4^{-1}t^{-2}x_3$$

where $\psi_0(v_{1,2}) = g_1$, $\psi_0(v_{1,4}) = g_2$, $\psi_0(v_{4,0}) = g_3$, $\psi_0(v_{4,1}) = g_4$, and in all other cases, $v_{i,j} = \varepsilon$ where $\psi_0(\varepsilon) = 1_G$.

Next, we insert special symbols into the words in $N_0$ to obtain the intermediate language $N_1$.

Let $\Lambda_1 = \Lambda_0 \cup T \cup \{B, C, B_0, C_0\}$ and $\Lambda = \Lambda_0 \cup \{B, C, B_0, C_0\}$. Let $v = (\gamma, h) \in G \cap H$ be written in the form of Equation (1). Notice that all terms of the form $v_i$ are part of the positive path. With $v_i$ as in Equation (2), before each $v_{i,j}$ we place the symbol $C$, with one exception. If $v_{i,j}$ is the label of the vertex $h$ of $S$ which is the final position of the lamplighter, then precede $v_{i,j}$ by the symbol $C_0$. Before each term $v_i$ we place the symbol $B$, with one exception. If $m_1 + \varsigma - 1 = 0$ we place the symbol $B_0$ in front of $v_i$, indicating the unique positive path where the lamplighter is at the vertex $1_H \in S$.

Let $N_1 \subseteq \Lambda_1^*$ denote the set of all words in $N_0$ where the symbols $\{B, C, B_0, C_0\}$ have been inserted as described. The word in $N_1$ for the element in Figure 3 is then

$$t^{-2}BCv_1,2CCv_1,4BCCCCC,v_4,0CCCBv_4,1CCC.$$  

To obtain the final normal form which will be the basis of the Cayley automatic structure for $G \cap H$, let $N \subseteq \Lambda^*$ denote the set of words in $N_1$ where all instances of the letters $t, x_1, \ldots, x_m, t^{-1}, x_1^{-1}, \ldots, x_m^{-1}$ from the set $T$ are removed. The word in $N$ for the element in Figure 3 is then

$$BCCCCCv_1,2CCv_1,4BCCCCC,v_4,0CCCBv_4,1CCC.$$  

Define the language

$$L_1 = \left\{ \prod_{i=1}^{p} (\beta_i \Gamma_{i,0} v_{i,0} \Gamma_{i,1} v_{i,1} \Gamma_{i,2} v_{i,2} \ldots \Gamma_{i,m} v_{i,m}) \left| \begin{array}{c} v_{i,j} \in L_0, \\ \beta_i \in \{B, B_0\}, \\ \Gamma_{i,j} \in \{C, C_0\}, \\ p \geq 1 \end{array} \right. \right\}.$$  

As $L_0$ is a regular language, it follows that $L_1$ is a regular language.

Recall that when $v \neq t^k x_q$, if $m_1 = k_q$ we allow $v_1$ to be trivial, otherwise $v_1$ must be nontrivial, and if $m_2 = k_q$ we allow $v_3$ to be trivial, otherwise $v_3$ must be nontrivial. These conditions are easily verified by a finite state automaton inspecting, respectively, the first and last expressions in the product representing an element of $L_1$ according to the following rules:

1. if $C_q$ occurs in the first factor in the product as expressed in Equation (3) then all $v_{i,j}$ may be $\varepsilon$ for $0 \leq j \leq m$; if not, at least one $v_{i,j}$ must be nontrivial.
2. if the $C_q$ occurs in the last factor in the product as expressed in Equation (3) then all $v_{i,j}$ may be $\varepsilon$ for $0 \leq j \leq m$; if not, at least one $v_{i,j}$ must be nontrivial.

Note that a finite state automaton can also easily verify that when all $v_i$ are trivial, we have a normal form corresponding to $t^k x_q$. Let $L_2 \subseteq L_1$ be the set of all strings in $L_1$ for which all three of these conditions are satisfied. Since these conditions are easily checked by a finite state automaton, and $L_1$ is a regular language, it follows that $L_2$ is a regular language.

Finally, we verify that the string has only one occurrence each of $B_q$ and $C_q$. Let

$$L = L_2 \cap \{pB_0 qC_r pC_q B_0 r \mid p, q, r \in (\Lambda \setminus \{B_0, C_q\})^* \}.$$  

It follows that $L$ is regular and that $L = N$.

As a further example, note that if $v = t^k x_q$, the corresponding word in $L$ is as follows:
(1) when \( n > 0 \), we have \( \text{isupp}(t^n x_q) = [0, n] \) and the corresponding word is 
\[ B_0 C^{m+1} (BC^{m+1})^{n-1} B C^n C^{m-q}; \]
(2) when \( n = 0 \), we have \( \text{isupp}(x_q) = [0, 0] \) and the corresponding word is 
\[ B_0 C^n C^{m-q}; \]
(3) when \( n < 0 \), we have \( \text{isupp}(t^n x_q) = [n, 0] \) and the corresponding word is 
\[ B C^n C^{m-q} (BC^{m+1})^{n-1} B_0 C^{m+1}. \]

Given a word \( \sigma \in L \), the symbols \( B_0 \) and \( C \) allow us to reconstruct the integer support of the corresponding element, as well as the final position of the lamplighter, that is, the coordinate \( h \). The words \( u_i,j \) correspond (via \( \psi_0 \)) to elements of \( G \) listed in a specified order. That is, we can deterministically reconstruct \( \gamma \in \bigoplus_{h \in H} (G)_h \) and \( h \in H \) from \( \sigma \). Formally, let \( \psi : L \rightarrow G \times H \) be the bijective map defined by 
\[ \psi(u) = \psi \left( \prod_{k=1}^{s} (\beta_k \Gamma_{k,0} u_{k,0} \Gamma_{k,1} u_{k,1} \Gamma_{k,2} u_{k,2} \cdots \Gamma_{k,m} u_{k,m}) \right) = t^m p_1 t p_2 \cdots t p_s t^j \]
where 
\[ p_i = \psi_0(v_i,0)x_1 \psi_0(v_i,1)x_2 \psi_0(v_i,2) \cdots x_{m-1} x_m \psi_0(v_i,m)x_m^{-1}, \]
with \( u_{i,j} = v_{i,j}, \beta_k \in \{B, B_0\}, \Gamma_{k,j} \in \{C, C_s\} \) and \( m_1 \) calculated from the positions of \( B_0 \) and \( C_s \) as described above.

We claim that \((\mathcal{S}, \Lambda, L, \psi)\) is a Cayley automatic structure for \( G \times H \). To prove this, we must show that for every generator \( s \in \mathcal{S} = S_0 \cup T \) the set 
\[ R_s = \{(u, v) \in L \times L | \psi(u)s =_{G \times H} \psi(v)\} \]
is a regular language, that is, recognised by a 2-tape synchronous automaton. It suffices to do this for \( s \in S_0 \cup \{x_1, \ldots, x_m, t\} \); see, for example, [3] Lemma 9.

First let \( s \in S_0 \) and suppose \((u, v) \in R_s \). Viewing \( \psi(u) \) as a configuration of \( \mathcal{S} \) with finitely many vertices marked with elements of \( G \) and a distinguished position for the lamplighter, we can easily see the effect of multiplication by \( s \) on the normal form. Let \( t^k x_q \) denote the vertex of \( \mathcal{S} \) which is the final position of the lamplighter in \( u \), marked by the element \( g_u \in G \). Let \( \rho_u \in L_0 \) be such that \( \psi_0(\rho_u) = g_u \). To obtain the normal form word for \( \psi(u)s \) we simply multiply \( \rho_u \) by \( s \) and verify that the multiplication is correct using the multiplier automaton \( M_s \) given as part of the given Cayley automatic structure on \( G \). Therefore we need to accept pairs of strings \((u, v) \in L \times L \) of the following form:
\[ u = (\Pi_{i=1}^{p} \beta_i \Pi_{j=0}^{m_{\alpha_{i,j}}} C_{\alpha_{i,j}}) \Theta_u \left( \Pi_{i=p+2}^{s} \beta_i \Pi_{j=0}^{m_{\alpha_{i,j}}} C_{\alpha_{i,j}} \right) \]
and
\[ v = (\Pi_{i=1}^{p} \beta_i \Pi_{j=0}^{m_{\alpha_{i,j}}} C_{\alpha_{i,j}}) \Theta_v \left( \Pi_{i=p+2}^{s} \beta_i \Pi_{j=0}^{m_{\alpha_{i,j}}} C_{\alpha_{i,j}} \right) \]
where \( \beta_i \in \{B, B_0\}, \alpha_{i,j} \in L_0 \),
\[ \Theta_u = \beta_{p+1}^{+} C_{\alpha_{p+1,0}} \cdots C_{s} \alpha_{p+1,r} \cdots \alpha_{p+1,m} \]
and
\[ \Theta_v = \beta_{p+1}^{+} C_{\alpha_{p+1,0}} \cdots C_{s} \alpha_{p+1,r} \cdots \alpha_{p+1,m} \]
where \((\alpha_{p+1,0}, \alpha_{p+1,r})\) is accepted by the multiplier automaton \( M_s \) given as part of the given Cayley automatic structure on \( G \). The bold highlighted symbols represent the only difference between the two words.

By [7] (see also [5] Lemma 8) the language \( L_0 \) is necessarily quasigeodesic. It follows that the difference between the lengths of \( \alpha_{p+1,0} \) and \( \alpha_{p+1,r} \) is uniformly bounded. As it is regular to check that two words are identical with a bounded shift, it follows that we can construct a 2-tape automaton which checks that the prefixes of \( u \) and \( v \) are identical, then calls \( M_s \) to read \((\alpha_{p+1,0}, \alpha_{p+1,r})\), and finally checks that the suffixes of \( u \) and \( v \) are identical (with a bounded shift). Thus \( R_s \) is a regular language.
Next let $x_i \in \{x_1, \ldots, x_m\}$, and suppose $(u, v) \in R_{x_i}$. Writing $\psi(u)$ as in Equation (1), we see that $\psi(u)x_i$ ends in the letters $x_qx_i$. The product $x_qx_i \in H$ is an element of some right coset \((t)x_r\). That is, $x_qx_i = t^kx_r$ for some $k$ and $r$. Viewing $\psi(u)$ and $\psi(v)$ as configurations in $S$, this means that the configurations are identical except for the final position of the lamplighter which is indicated by $C_s$ in the normal form. Note that as $x_q$ and $x_i$ vary among the finite set of coset representatives, there are only a finite number of possible values of $(k, r)$ which arise.

The elements $\psi(u)$ and $\psi(v)$ may or may not have identical integer support. For example if $\psi(u) = t^{-10}g_1 t^{20}g_2 t^{-5}x_q$ and $x_qx_i = t^{-7}x_r$ then $\text{isupp}(\psi(u)) = \text{isupp}(\psi(v))$, whereas if $\psi(u) = t^{-10}g_1 t^{20}g_2 t^{-5}x_q$ and $x_qx_i = t^{-17}x_r$ then $\text{isupp}(\psi(u)) \neq \text{isupp}(\psi(v))$.

If $\text{isupp}(\psi(u)) = \text{isupp}(\psi(v))$, then we simply need to check the two strings are identical except for the location of $C_s$. If $\psi(u)$ ends in $x_q$ when written as in Equation (1), we have $x_qx_i = t^kx_r$. Let $\pi: \Lambda^* \to \{C, C_s, B_0\}^*$ be a homomorphism which is the identity on $C, C_s, B_0$ and sends all other letters to $\varepsilon$. Then $\pi(u)$ and $\pi(v)$ are identical strings except for the location of $C_s$ in each string. Observe the letter $B_0$ is in the same position in each string since the integer supports of $\psi(u)$ and $\psi(v)$ are the same. Further observe that there exists an integer $s_{q, i}$ such that for every pair $(u, v) \in R_{x_i}$ which have the same integer support, if $C_s$ is the $x$th letter of $\pi(u)$ and the $y$th letter of $\pi(v)$, then $x - y = s_{q, i}$.

Consider the language $X_{q, i} \subseteq \{C, C_s, B_0\}^* \times \{C, C_s, B_0\}^*$ consisting of all pairs of strings, each of which contains exactly one $C_s$ letter and one $B_0$ letter, where $C_s$ is the $x$th letter of the first string and the $y$th letter of the second string with $x - y = s_{q, i}$, and $B_0$ is in the same position in both strings. Since these conditions are regular to check, $X_{q, i}$ is a regular language.

Let
\[
\kappa: \Lambda^* \times \Lambda^* \to \{C, C_s, B_0\}^* \times \{C, C_s, B_0\}^*
\]
be the map which in each coordinate is the identity on $C, C_s$ and $B_0$ and sends all other letters to $\varepsilon$. Let $Y \subseteq \Lambda^* \times \Lambda^*$ be the language consisting of all pairs of strings such that for every positive integer $z$ the $z$th letter of the first string and the second string is the same unless one of these letters is $C_s$ and the other is $C$. The language $Y$ is regular. Then the language
\[
\kappa^{-1}(X_{q, i}) \cap (L \times L) \cap Y
\]
is regular, and the union of these languages for $0 \leq q \leq m + 1$ is exactly the subset of $R_{x_i}$ for which multiplication by $x_i$ does not change the integer support for the first entry.

Now consider all the possible ways that the integer support of $\psi(u)$ can change upon multiplication by $x_i$. Again assume $\psi(u)$ ends in $x_q$ when written as in Equation (1), and $x_qx_i = t^kx_r$. We must consider the following cases.

1. $\psi(u) = t^n x_q$ and $k \neq 0$.
2. $\psi(u) = t^{m_1} v_1 t^{m_2} \ldots t^{m_j} x_q$ with $\text{isupp}(\psi(u)) = [m_1, m_2], j \leq 0$ and
   a. $k > -j$; in this case the integer support of $v$ extends further to the right of $m_2$,
   b. $k < m_1 - m_2 - j$; in this case the integer support of $v$ extends further to the left of $m_1$.

Each of these cases can be handled in a manner similar to the above case, by considering the relative positions of $C_s$ and $B_0$ in $\pi(u), \pi(v)$. For the first case, if $n > 0, k > -n$ then
\[
u = B_0 C_{s}^{m+1} (B C_{s}^{m+1})^{n-1} B C_{s}^{n} C_{s}^{m-n}.
\]
and if $n > 0, k < -n$ then
\[
u = B_0 C_{s}^{m+1} (BC_{s}^{m+1})^{n-1} B C_{s}^{n-k-1} C_{s}^{m-n}.
\]
Analogous pairs of expressions can be worked out for $n \leq 0$; clearly all such pairs can be recognised by 2-tape automata since $q, i, k, r$ are fixed. We leave details of the remaining cases to the reader.

Finally, suppose $(u, v) \in R_t$. Writing $\psi(u)$ as in Equation (1), we see that $\psi(u)t$ ends in the letters $x_q t$. Once again, we can consider the case where the integer support of $\psi(u)$ does not
change, in which case we merely need to check the location of the $C_s$ letters in each word, and separately the case where the integer support of $\psi(u)$ differs at one endpoint from the integer support of $\psi(v)$. We follow the same reasoning as in the previous case of multiplication by $x_i$; note that $x_q t$ is in some right coset of $Z$ in $H$, so we can write $x_q t = t^k x_r$, for a possibly different coset representative $x_r$. We can therefore show that $R_t$ is a regular language as well. The regular languages $R_s$, $R_{x_i}$ and $R_t$ complete the construction of the Cayley automatic structure $(S, A, L, \psi)$ for $G \wr H$. □
