FOUR-MANIFOLDS UP TO CONNECTED SUM WITH COMPLEX PROJECTIVE PLANES

DANIEL KASPROWSKI, MARK POWELL, AND PETER TEICHNER

Abstract. Based on results of Kreck, we show that closed, connected 4-manifolds up to connected sum with copies of the complex projective plane are classified in terms of the fundamental group, the orientation character and an extension class involving the second homotopy group. For fundamental groups that are torsion free or have one end, we reduce this further to a classification in terms of the homotopy 2-type.

1. Introduction

We give an explicit, algebraic classification of closed, connected 4-manifolds up to connected sum with copies of the complex projective plane $\mathbb{CP}^2$.

After the great success of Thurston's geometrisation of 3-manifolds, the classification of closed 4-manifolds remains one of the most exciting open problems in topology. The exactness of the surgery sequence and the $s$-cobordism theorem are known for topological 4-manifolds with good fundamental groups, a class of groups that includes all solvable groups [FT95, KQ00]. However, a homeomorphism classification is only known for closed 4-manifolds with trivial [Fre82], cyclic [FQ90, Kre99, HK93] or Baumslag-Solitar [HKT09] fundamental group.

For smooth 4-manifolds, gauge theory provides obstructions even to once hoped-for foundational results like simply connected surgery and $h$-cobordism, which hold in all higher dimensions. There is no proposed diffeomorphism classification in sight, indeed understanding homotopy 4-spheres is beyond us at present. Most of the invariants derived from gauge theory depend on an orientation and do not change under connected sum with $\mathbb{CP}^2$, but the differences dissolve under connected sum with $\mathbb{CP}^2$. This suggests considering 4-manifolds up to $\mathbb{CP}^2$-stable diffeomorphism.

In Section 1.1 we spell out all the details, and discuss some history, but first we would like to state our main result. The 2-type of a connected manifold $M$ consists of its 1-type $(\pi_1(M), w_1(M))$ together with the second homotopy group $\pi_2(M)$ and the $k$-invariant $k(M) \in H^3(\pi_1(M); \pi_2(M))$ that classifies the second Postnikov stage of $M$ via a fibration $K(\pi_2(M), 2) \to P_2(M) \to K(\pi_1(M), 1)$.

**Theorem A.** Two closed, connected, smooth 4-manifolds with 1-type $(\pi, w)$ are $\mathbb{CP}^2$-stably diffeomorphic if and only if their 2-types $(\pi, w, \pi_2, k)$ are stably isomorphic, provided $\pi$ is

(i) torsion-free; or
(ii) infinite with one end; or
(iii) finite with $H_4(\pi; \mathbb{Z}^w)$ annihilated by 4 or 6.

2020 Mathematics Subject Classification. 57N13, 57N65.

Key words and phrases. 4-manifolds, $\mathbb{CP}^2$-stable classification, Postnikov 2-type, $k$-invariant.
Definition 1.4 discusses the notion of a stable isomorphism of 2-types. Condition (iii) is satisfied for all \((\pi, w)\) with \(\pi\) finite and \(w: \pi \to \{\pm 1\}\) nontrivial on the centre of \(\pi\), as explained in Remark 1.5. A curious consequence of Theorem A is worth pointing out.

**Corollary 1.1.** Let \(M_1\) and \(M_2\) be two closed, connected, smooth 4-manifolds with fundamental group \(\pi\) as in Theorem A. If \(M_1\) and \(M_2\) have stably isomorphic 2-types, then the equivariant intersection forms on \(\pi_2(M_1)\) and \(\pi_2(M_2)\) become isometric after stabilisation by standard forms \((\pm 1)\).

In the simply connected case, this follows from the classification of odd indefinite forms by their rank and signature, since for two given simply connected 4-manifolds, the rank and signatures of their intersection forms can be made to coincide by \(\mathbb{C}P^2\)-stabilisation. For general fundamental groups, the underlying module does not algebraically determine the intersection form up to stabilisation, but Theorem A says that equivariant intersection forms of 4-manifolds with the appropriate fundamental group are controlled in this way.

1.1. **Definitions of various notions of stability.** The connected sum of a smooth 4-manifold \(M\) with \(\mathbb{C}P^2\) depends on a choice of embedding \(D^4 \hookrightarrow M\), where isotopic embeddings yield diffeomorphic connected sums. A complex chart gives a preferred choice of isotopy class of embeddings \(D^4 \subset \mathbb{C}^2 \hookrightarrow \mathbb{C}P^2\). We will assume that the manifolds we consider are connected unless stated otherwise. If \(M\) admits an orientation \(\mathfrak{o}\), there are two distinct isotopy classes of embeddings \(D^4 \hookrightarrow M\), exactly one of which is orientation preserving. So we obtain two manifolds \((M, \mathfrak{o})\#\mathbb{C}P^2\) and \((M, -\mathfrak{o})\#\mathbb{C}P^2 \cong (M, \mathfrak{o})\#\overline{\mathbb{C}P^2}\) that in general are not diffeomorphic. On the other hand if \(M\) is not orientable, we can isotope an embedding \(D^4 \hookrightarrow M\) around an orientation reversing loop to see that there is an essentially unique connected sum \(M\#\mathbb{C}P^2\).

While our theorems are stated for unoriented 4-manifolds, we will often make some choice of a (twisted) fundamental class of \(M\). But for our results the specific choice will not matter since we will usually factor out by the effect of this choice.

A 1-type \((\pi, w)\) consists of a group \(\pi\) and a homomorphism \(w: \pi \to \{\pm 1\}\). A connected manifold \(M\) has 1-type \((\pi, w)\) if there is a map \(c: M \to B\pi\) such that \(c_*: \pi_1(M) \to \pi_1(B\pi) = \pi\) is an isomorphism and \(w \circ c_*: \pi_1(M) \to \{\pm 1\}\) determines the first Stiefel-Whitney class \(w_1(M) \in H^1(M; \mathbb{Z}/2) \cong \text{Hom}(\pi_1(M), \mathbb{Z}/2)\). All our results are based on the following theorem.

**Theorem 1.2** (Kreck [Kre99]). Two closed, connected, smooth 4-manifolds \(M_1\) and \(M_2\) are \(\mathbb{C}P^2\)-stably diffeomorphic if and only if they have the same 1-type \((\pi, w)\) and the images of some choices of (twisted) fundamental classes \((c_1)_* [M_1]\) and \((c_2)_* [M_2]\) coincide in \(H_4(\pi; \mathbb{Z}^w)/\pm \text{Aut}(\pi)\).

The map induced on homology by the classifying map \(c: M \to B\pi\) sends the (twisted) fundamental class \([M] \in H_4(M; \mathbb{Z}^{w_1(M)})\) to \(H_4(\pi; \mathbb{Z}^w)\). Here the coefficients are twisted using the orientation characters \(w_1(M)\) and \(w\) to give \(\mathbb{Z}^{w_1(M)}\) and \(\mathbb{Z}^w\) respectively. The quotient by \(\text{Aut}(\pi)\) takes care of the different choices of identifications \(c_*\) of the fundamental groups with \(\pi\), and the sign \(\pm\) removes dependency on the choice of fundamental class. In particular, within a 1-type \((\pi, w)\) such that \(H_4(\pi; \mathbb{Z}^w) = 0\), there is a single \(\mathbb{C}P^2\)-stable diffeomorphism class. Kreck’s result also implies that if \(M_1\) and \(M_2\) are homotopy equivalent then they are \(\mathbb{C}P^2\)-stable.
diffeomorphic. We will give a self-contained proof of Theorem 1.2 in Section 2, that proceeds by simplifying a handle decomposition.

Remark 1.3. Kreck’s theorem, as well as our results, also hold for topological 4-manifolds, with the additional condition that the Kirby-Siebenmann invariants ks(M_i) ∈ Z/2 coincide for i = 1, 2 cf. [Tei92, Chapter 5]. A topological 4-manifold M has a smooth structure CP^2-stably if and only if ks(M) = 0. Using the existence of simply-connected closed 4-manifolds with non-trivial Kirby-Siebenmann invariant, one can quickly deduce the topological result from the smooth one. See Section 1.5 for more details. We therefore focus on the smooth category from now on.

A connected sum with CP^2 changes the second homotopy group by adding a free summand π_2(M # CP^2) ∼= π_2(M) ∪ Λ, where here and throughout the paper we write [Λ := Z[π_1(M)] ∼= Z[π]] for the group ring. The k-invariant k(M) ∈ H^3(π; π_2(M)) maps via (k(M), 0) to k(M # CP^2) under the composition

\[ H^3(\pi; \pi_2(M)) \to H^3(\pi; \pi_2(M)) \oplus H^3(\pi; \Lambda) \to H^3(\pi; \pi_2(M # CP^2)). \]

Definition 1.4. A stable isomorphism of 2-types is a pair (φ_1, φ_2) consisting of an isomorphism φ_2: π_1(M_1) → π_1(M_2) with φ_2(w_1(M_2)) = w_1(M_1), together with an isomorphism, for some r, s ∈ N_0,

φ_2: π_2(M_1) ∪ Λ' → π_2(M_2) ∪ Λ' satisfying φ_2(g · x) = φ_1(g) · φ_2(x)

for all g ∈ π_1(M_1) and for all x ∈ π_2(M_1) ∪ Λ'. We also require that (φ_1, φ_2) preserves k-invariants in the sense that

(φ_1^{-1}, φ_2): H^3(π_1(M_1); π_2(M_1) ∪ Λ') \to H^3(π_1(M_2); π_2(M_2) ∪ Λ'),

\[ (k(M_1), 0) \mapsto (k(M_2), 0). \]

Remark 1.5. Observe that, by design, a CP^2-stable diffeomorphism induces a stable isomorphism of 2-types, so the ‘only if’ direction of Theorem A holds for all groups. In addition, for an arbitrary fundamental group π, the stable CP^2-stable diffeomorphism class represented by those manifolds with c_4[M] = 0 ∈ H_4(π; Z^w) is always detected by the stable isomorphism class of their 2-type (π, w, π_2, k), cf. Corollary 7.2.

Condition (iii) in Theorem A is satisfied for all (π, w) with π finite and w non-trivial on the centre of π. To see this, apply [Bro82, Proposition III.8.1] for some element g in the centre of π with w(g) nontrivial, to show that multiplication by –1 acts as the identity. Hence every nontrivial element in H_4(π; Z^w) has order two.

1.2. Necessity of assumptions. Next we present examples of groups demonstrating that hypotheses of Theorem A are necessary. The details are given in Section 9.1. We consider a class of infinite groups with two ends, namely π = Z × Z/p, and closed, orientable 4-manifolds, so w = 0. In this case the 2-type does not determine the CP^2-stable diffeomorphism classification, as the following example shows.

Example 1.6. Let L_{p_1,q_1} and L_{p_2,q_2} be two 3-dimensional lens spaces, which are closed, oriented 3-manifolds with cyclic fundamental group Z/p_i and universal covering S^3. Assume that p_i ≥ 2 and 1 ≤ q_i < p_i. The 4-manifolds M_i := S^1 × L_{p_i,q_i}, i = 1, 2, have π_2(M_i) = {0}. Whence their 2-types are stably isomorphic if and only if π_1(L_{p_1,q_1}) ∼= π_1(L_{p_2,q_2}), that is if and only if p_1 = p_2. However, we will show
that the 4-manifolds $M_1$ and $M_2$ are $\mathbb{C}P^2$-stably diffeomorphic if and only if $L_{p_1,q_1}$ and $L_{p_2,q_2}$ are homotopy equivalent.

It is a classical result that there are homotopically inequivalent lens spaces with the same fundamental group. In fact it was shown by J.H.C. Whitehead that $L_{p,q_1}$ and $L_{p,q_2}$ are homotopy equivalent if and only if their $\mathbb{Q}/\mathbb{Z}$-valued linking forms are isometric. See Section 9.1 for more details and precise references.

We do not know an example of a finite group $\pi$ for which the conclusion of Theorem A does not hold. Thus the following question remains open.

**Question 1.7.** Does the conclusion of Theorem A hold for all finite groups?

In [KT21], the first and third authors showed that for 4-manifolds with finite fundamental group, if one adds the data of the stable class of the equivariant intersection form to the 2-type, then the $\mathbb{C}P^2$-stable class is determined.

### 1.3. Is the $k$-invariant required?

In Section 8, we will show that while Theorem A applies, the $k$-invariant is not needed for the $\mathbb{C}P^2$-stable classification of 4-manifolds $M$ with fundamental group $\pi$, where $\pi$ is also the fundamental group of some closed aspherical 4-manifold. A good example of such a 4-manifold is the 4-torus, with fundamental group $\mathbb{Z}^2$. More generally a surface bundle over a surface, with neither surface equal to $S^2$ nor $\mathbb{RP}^2$, is an aspherical 4-manifold. We know from Theorem 1.2 that the $\mathbb{C}P^2$-stable equivalence classes are in bijection with $\mathbb{N}_0$ because $H_4(\pi;\mathbb{Z}^w) \cong \mathbb{Z}$, but it is not obvious how to compute this invariant from a given 4-manifold $M$.

We will show in Theorem 8.1 that in this case the stable isomorphism type of the $\Lambda$-module $\pi_2(M)$ determines the $\mathbb{C}P^2$-stable diffeomorphism class of $M$. Assuming moreover that $H^1(\pi;\mathbb{Z}) \neq 0$, we will show in Theorem 8.2 that the highest torsion in the abelian group of twisted co-invariants $\mathbb{Z}^w \otimes_{\Lambda} \pi_2(M)$ detects this stable isomorphism class in almost all cases.

On the other hand, there are many cases where Theorem A applies and the $k$-invariant is indeed required, as the next example shows. This example also leverages the homotopy classification of lens spaces.

**Example 1.8.** For the following class of 4-manifolds, the $k$-invariant is required in the $\mathbb{C}P^2$-stable classification. Let $\Sigma$ be an aspherical 3-manifold. Consider a lens space $L_{p,q}$ with fundamental group $\mathbb{Z}/p$ and form the 4-manifold $M(L_{p,q}, \Sigma) := S^1 \times (L_{p,q}/\Sigma)$ with fundamental group $\pi = \mathbb{Z} \times (\mathbb{Z}/p * \pi_1(\Sigma))$.

We will show in Section 9.2 that these groups have one end and hence our Theorem A applies, so the 2-type determines the $\mathbb{C}P^2$-stable classification. Similarly to Example 1.6, we will show that two 4-manifolds of the form $M(L_{p,q}, \Sigma)$ are $\mathbb{C}P^2$-stably diffeomorphic if and only if the involved lens spaces are homotopy equivalent. However, the $\Lambda$-modules $\pi_2(M(L_{p,q}, \Sigma))$ will be shown to depend only on $p$. Since there are homotopically inequivalent lens spaces with the same fundamental group, we deduce that the stable isomorphism class of $\pi_2(M(L_{p,q}, \Sigma))$ is a weaker invariant than the full 2-type $(\pi, 0, \pi_2, k)$.

### 1.4. Extension classes and the proof of Theorem A.

In order to prove Theorem A, we will translate the image of the fundamental class $c_*[M] \in H_4(\pi;\mathbb{Z}^w)$ completely into algebra.

Let $(C_*, d_*)$ and $(C'_*, d'_*)$ be free resolutions of $\mathbb{Z}$ as a $\Lambda$-module with $C_i$ and $C'_i$ finitely generated for $i = 0, 1, 2$. See Lemma 5.8 for an explanation of the
natural isomorphism in the following proposition. Note that \( d_{w,2}' \) is the dual of \( d_{2}' \) twisted by the orientation character \( w \), see Section 3 for our conventions.

**Proposition 1.9.** There is a natural isomorphism

\[
\psi(C_*, C'_i): H_4(\pi; \mathbb{Z}^w) \xrightarrow{\cong} \text{Ext}_A^1(\ker d_{w,2}', \ker d_2).
\]

As always, \( M \) is a closed, connected, smooth 4-manifold together with a 2-equivalence \( c: M \to B\pi \) such that \( c^*(w) = w_3(M) \). We choose a (twisted) fundamental class and a handle decomposition of \( M \) and consider the chain complex \((C_*^M, d_*^M)\) of left \( \Lambda \)-modules, freely generated by the handle in the universal cover \( \tilde{M} \). Note that by the Hurewicz theorem, \( \pi_2(M) \cong H_2(M) \cong \ker d_2/\im d_3 \). Let \( M^k \) be \( M \) with the dual handle decomposition and denote its \( \Lambda \)-chain complex by \((C_*^M, d_*^M)\). Then by Poincaré duality \( C_*^M \cong C_*^M \). In particular, \( \ker d_{w,2}' \cong \ker d_3 \) and we will use this isomorphism implicitly in Proposition 1.10 below. Note that picking the other orientation of \( M \) changes this isomorphism by a sign. Thus in the next proposition the image of \( c_*[M] \) in \( \text{Ext}_A^1(\ker d_3, \ker d_2) \) is independent of the choice of \([M]\).

**Proposition 1.10.** Let \( D_* \) be a free resolution of \( \mathbb{Z} \) starting with \( D_0 = C_*^M \) for \( i = 0, 1, 2 \) and let \( D'_* \) be a free resolution of \( \mathbb{Z} \) starting with \( D'_0 = C_*^M \) for \( i = 0, 1, 2 \). The isomorphism \( \Psi(D_*, D'_*) \) from Proposition 1.9 sends \( c_*[M] \) to the extension

\[
0 \to \ker d_2 \xrightarrow{(i-p)^T} C_2 \oplus \ker d_2/\im d_3 \xrightarrow{(i'-p')} \ker d_3 \to 0
\]

where \( i, i' \) are the inclusions and \( p, p' \) are the projections. In particular, \( c_*[M] = 0 \) if and only if this extension is trivial, and hence \( \pi_2(M) \) is stably isomorphic to the direct sum \( \ker d_2 \oplus \ker d_3 \).

Proposition 1.10 is a generalisation of [HK88, Proposition 2.4], where the theorem was proven for oriented manifolds with finite fundamental groups. The fact that \( \pi_2(M) \) fits into such an extension for general groups was shown by Hambleton in [Ham09]. The above proposition implies the following, because \( c_*[M] \in H_4(\pi; \mathbb{Z}^w) \) determines the \( \mathbb{CP}^2 \)-stable diffeomorphism type by Theorem 1.2.

**Theorem 1.11.** Two closed, connected, smooth 4-manifolds \( M_1 \) and \( M_2 \) with 1-type \((\pi, w)\) are \( \mathbb{CP}^2 \)-stably diffeomorphic if and only if the extension classes determining \( \pi_2(M_1) \) and \( \pi_2(M_2) \) coincide in

\[
\text{Ext}_A^1(\ker d_{w,2}' \wedge d_2) \cong H_4(\pi; \mathbb{Z}^w)
\]

modulo the action of \( \pm \text{Aut}(\pi) \).

This result translates the \( H_4(\pi; \mathbb{Z}^w) \) invariant into algebra for all groups. There is a version of Theorem 1.11 where we do not need to divide out by \( \text{Aut}(\pi) \); there is a stable diffeomorphism over \( \pi \) if the extension classes agree (up to sign) for a specific choice of identifications \( \pi_1(M_1) \xrightarrow{\cong} \pi \).

In Section 6 and Section 7, we will derive Theorem A from Theorem 1.11. Since two isomorphic extensions yield stably isomorphic second homotopy groups, we seek a kind of converse by adding the datum of the \( k \)-invariant. In the purely algebraic Section 6, given a 1-cocycle \( f: C_w^1 \to \ker d_2 \) representing an extension class in \( \text{Ext}_A^1(\ker d_{w,2}' \wedge d_2) \), we construct a \( \Lambda \)-module chain complex \( C_f \) by attaching (trivial) 2-chain and (non-trivial) 3-chains to \( C_2 \to C_1 \to C_0 \). We show that \( \Theta: f \mapsto C_f \) gives a well-defined map from our extension group \( \text{Ext}_A^1(\ker d_{w,2}' \wedge d_2) \) to
stable isomorphism classes in a category $s\text{Ch}_2(\pi)$ of chain complexes over $\Lambda = \mathbb{Z}[\pi]$ that are the algebraic analogue of the 2-type. Moreover, if $f$ is the extension class coming from a 4-manifold $M$, then $\Theta(f) = C_f$ agrees in $s\text{Ch}_2(\pi)$ with the stable class determined by the chain complex of $P_2(M)$ of $M$. Recall that $P_2(M)$ is determined by 2-type of $M$, which includes the $k$-invariant. In Theorem 6.6 we then show that the stable class of $C_f$ detects our extension class modulo the action of the automorphisms of $\text{coker} d^n_2$. That is, $\Theta$ induces an injective map on the quotient of the extensions by the automorphisms of $\text{coker} d^n_2$. Finally, in Lemma 6.8 we analyse the action of such automorphisms on the extension group $\text{Ext}^1_\Lambda(\text{coker} d^n_2, \ker d_4)$ and show that under the assumptions of Theorem A, the automorphisms can change the extension class at most by a sign. Since our manifolds are unoriented, the sign ambiguity is already present, so Theorem A follows.

1.5. Additional remarks.

Topological manifolds. As mentioned in Remark 1.3, Theorem A and Theorem 1.11 hold for closed, connected topological 4-manifolds $M$, with the additional assumption that the Kirby-Siebenmann invariants $\text{ks}(M_i) \in \mathbb{Z}/2$ are equal. Here is the proof, which is well-known to the experts.

Let $M_1$ and $M_2$ be two closed, connected, topological 4-manifolds, with $\text{ks}(M_1) = \text{ks}(M_2)$, and suppose that the conditions of one of the two theorems mentioned above are satisfied. Note that all the conditions involve algebraic topological invariants, so are category independent. As explained in [FNOP19, Section 8], it follows from Kirby-Siebenmann [KS77, pp. 321–2] and Freedman-Quinn [FQ90, Sections 8.6] that a 4-manifold $M$ admits a smooth structure $S^2 \times S^2$-stably if and only if $\text{ks}(M) = 0$. Since $S^2 \times S^2$ and $S^4$ are $\mathbb{CP}^2$-stably diffeomorphic, we deduce that there exists a smooth structure on $M$ $\mathbb{CP}^2$-stably if and only if $\text{ks}(M) = 0$. To apply this, if necessary connect sum both $M_1$ and $M_2$ with the Chern manifold $\ast \mathbb{CP}^2$ with nontrivial Kirby-Siebenmann invariant [FQ90, Section 10.4], noting that $\text{ks}$ is additive [FQ90, Section 10.2B], [FNOP19, Section 8], to obtain a $\mathbb{CP}^2$-stably smoothable pair. Then the smooth result applies, so that the manifolds are $\mathbb{CP}^2$-stably diffeomorphic. Now add another copy of $\ast \mathbb{CP}^2$ to both: by the classification of simply-connected 4-manifolds [FQ90, Theorem 10.1] we have $\ast \mathbb{CP}^2 \# \ast \mathbb{CP}^2 \approx \mathbb{CP}^2 \# \mathbb{CP}^2$, so this returns us to the original $\mathbb{CP}^2$-stable homeomorphism classes, which we now know coincide.

Multiplicative Invariants. Consider an invariant $I$ of closed, oriented 4-manifolds valued in some commutative monoid, that is multiplicative under connected sum and invertible on $\mathbb{CP}^2$ and $\overline{\mathbb{CP}}^2$. For example, the generalised dichromatic invariant of [BB17], $I(M) \in \mathbb{C}$, is such an invariant.

It follows from Theorem 1.2 that every such invariant is determined by the fundamental group $\pi_1(M)$, the image of the fundamental class in $H_4(\pi; \mathbb{Z})$, its signature $\sigma(M)$ and its Euler characteristic $\chi(M)$. More precisely, given a second manifold $N$ with the same fundamental group and $c_4[N] = c_4[M] \in H_4(\pi; \mathbb{Z})$, one has

$$I(N) = I(M) \cdot I(\mathbb{CP}^2)^{\Delta \pi + \Delta \sigma} \cdot I(\overline{\mathbb{CP}}^2)^{\Delta \pi - \Delta \sigma},$$

where $\Delta \sigma := \sigma(N) - \sigma(M)$ and $\Delta \chi := \chi(N) - \chi(M)$. For example, for every manifold $N$ with fundamental group $\mathbb{Z}$ we have

$$I(N) = I(S^1 \times S^3) \cdot I(\mathbb{CP}^2)^{\chi(N) + \sigma(N)} \cdot I(\overline{\mathbb{CP}}^2)^{\chi(N) - \sigma(N)}.$$
For the generalised dichromatic invariant, the values on $\mathbb{CP}^2$, $\mathbb{CP}^2$, and $S^1 \times S^3$ are calculated in [BB17, Sections 3.4 and 6.2.1]. Moreover, in the cases that Theorem A holds, any invariant as above is equivalently determined by the 2-type, the signature and the Euler characteristic. See [Reu20] for a comprehensive extension of this discussion.

Appearance of $\mathbb{CP}^2$-stable diffeomorphisms in the literature. Manifolds up to $\mathbb{CP}^2$-stable diffeomorphism are also considered by Khan and Smith in [KS19]. There the existence of incompressible embeddings of 3-manifolds corresponding to amalgamated products of the fundamental group is studied. Note that Khan and Smith use the term bistable instead of $\mathbb{CP}^2$-stable.

Relation to the symmetric signature. We also note that the proofs of Sections 5 and 6 comprise homological algebra, combined with Poincaré duality to stably identify $\text{coker}(d_3)$ with $\text{coker} d_2^\natural$, during the passage from Proposition 1.9 to Theorem 1.11. The proofs could therefore be carried out if one only retained the symmetric signature in $L^4(\Lambda, w)$ of the 4-manifold [Ran80a, Ran80b], that is the chain cobordism class of a $\Lambda$-module handle chain complex of $M$ together with chain-level Poincaré duality structure.

Organisation of the paper. Section 2 gives a self-contained proof of Kreck’s Theorem 1.2. After establishing conventions for homology and cohomology with twisted coefficients in Section 3, we present an extended Hopf sequence in Section 4, and use this to give a short proof of Theorem A in a special case.

Section 5 proves Propositions 1.9 and 1.10, which together express the fourth homology invariant of Theorem 1.2 in terms of an extension class involving $\pi_2(M)$. Section 6 refines this in terms of the 2-type for certain groups. This is applied in the proof of Theorem A in Section 7.

We then give a further refinement in Section 8: in the special case that $\pi$ is the fundamental group of some aspherical 4-manifold, the $\mathbb{CP}^2$-stable classification is determined by the stable isomorphism class of $\pi_2(M)$, and if in addition $H^1(\pi; \mathbb{Z}) \neq 0$ then the classification can essentially be read off from $\mathbb{Z}^w \otimes_\Lambda \pi_2(M)$.

Finally, Section 9 discusses the examples mentioned in Sections 1.2 and 1.3, showing first that the hypotheses of Theorem A are in general necessary and then showing that for many fundamental groups falling within the purview of Theorem A, knowledge of the stable isomorphism class of $\pi_2(M)$ does not suffice and the $k$-invariant is required.

Acknowledgements. We are delighted to have the opportunity to thank Diarmuid Crowley, Jim Davis, Matthias Kreck, Markus Land, Wolfgang Lück, Ian Hambleton, Henrik Rüping, Mark Ullmann and Christoph Winges for many useful and interesting discussions on this work. We also thank the anonymous referee for several useful suggestions that helped improve the exposition.

The authors thank the Max Planck Institute for Mathematics and the Hausdorff Institute for Mathematics in Bonn for financial support and their excellent research environments. The second author gratefully acknowledges an NSERC Discovery Grant, and was partially supported by EPSRC New Investigator grant EP/T028335/1 and EPSRC New Horizons grant EP/V04821X/1.
2. CP²-stable classification

Let \((\pi, w)\) be a 1-type, that is a finitely presented group \(\pi\) together with a homomorphism \(w: \pi \to \mathbb{Z}/2\). Let \(\xi: BSO \times B\pi \to BO\) be a fibration that classifies the stable vector bundle obtained as the direct sum of the orientation double cover \(BSO \to BO\) and the line bundle \(L: B\pi \to BO(1)\) classified by \(w\). Let \(\Omega_4(\pi, w) := \Omega_4(\xi)\) denote the bordism group of closed 4-manifolds \(M\) equipped with a \(\xi\)-structure, namely a lift \(\tilde{\nu}: M \to BSO \times B\pi\) of the stable normal bundle \(\nu: M \to BO\) along \(\xi\), modulo cobordisms with the analogous structure extending the \(\xi\)-structure on the boundary.

**Lemma 2.1.** The map \(\Omega_4(\pi, w) \to H_0(\pi; \mathbb{Z}^w) \times H_4(\pi; \mathbb{Z}^w)\) given by sending \([M, \tilde{\nu}]\) to the pair \((\sigma(M), (p_2 \circ \tilde{\nu})_*(|M|))\) is an isomorphism. Here if \(M\) is orientable \((w = 0)\), \(H_0(\pi; \mathbb{Z}^w) \cong \mathbb{Z}\) and \(\sigma(M) \in \mathbb{Z}\) is the signature. If \(w\) is nontrivial, then \(H_0(\pi; \mathbb{Z}^w) \cong \mathbb{Z}/2\) and \(\sigma(M) \in \mathbb{Z}/2\) denotes the Euler characteristic mod 2.

We use \([M] \in H_4(M; \mathbb{Z}^w) \cong \mathbb{Z}\) for the fundamental class of \(M\) determined by \(\tilde{\nu}: M \to BSO \times B\pi\).

**Proof.** By the Pontryagin-Thom construction, the bordism group \(\Omega_4(\pi, w)\) is isomorphic to \(\pi_5(MSO \wedge Th(L))\), where \(Th(L)\) is the Thom space corresponding to the real line bundle \(L\) and \(MSO\) is the oriented Thom spectrum. Shift perspective to think of \(\pi_5(MSO \wedge Th(L))\) as the generalised reduced homology group \(\pi_5(MSO \wedge \_\_\_)\) of \(Th(L)\), isomorphic to the group \(\widetilde{\Omega}_5^{SO}(Th(L))\) of reduced 5-dimensional oriented bordism over \(Th(L)\). The Atiyah-Hirzebruch spectral sequence gives an exact sequence

\[
0 \to H_i(Th(L); \mathbb{Z}) \to \widetilde{\Omega}_5^{SO}(Th(L)) \to H_{i+5}(Th(L); \mathbb{Z}) \to 0
\]

because in the range \(0 \leq i \leq 4\) we have that \(\Omega_i^{SO} \cong \mathbb{Z}\) for \(i = 0, 4\) and zero otherwise. Since \(w_1(L) = w\), the Thom isomorphism theorem [Rud98, Theorem IV.5.7], [Lic02, Theorem 3.31] shows that

\[
H_1(Th(L); \mathbb{Z}) \cong H_0(\pi; \mathbb{Z}^w) \quad \text{and} \quad H_5(Th(L); \mathbb{Z}) \cong H_4(\pi; \mathbb{Z}^w).
\]

Using this the above short exact sequence translates to

\[
0 \to H_0(\pi; \mathbb{Z}^w) \to \Omega_4(\pi, w) \to H_4(\pi; \mathbb{Z}^w) \to 0.
\]

In the orientable case \(w = 0\), the group \(H_0(\pi; \mathbb{Z}^w) \cong H_0(\pi; \Omega_3^{SO}) \cong \Omega_3^{SO} \cong \mathbb{Z}\), while in the nonorientable case \(w \neq 0\), we have \(H_0(\pi; \mathbb{Z}^w) \cong H_0(\pi; (\Omega_3^{SO})^w) \cong \mathbb{Z} \otimes \wedge (\Omega_3^{SO})^w \cong \mathbb{Z}/2\). In both cases, the image of the inclusion \(H_0(\pi; \mathbb{Z}^w) \to \Omega_4(\pi, w)\) is generated by \([\mathbb{CP}^2]\) with trivial map to \(B\pi\).

To see that the short exact sequence splits, use that the signature is an additive invariant of oriented bordism, that the Euler characteristic mod 2 is an additive bordism invariant, and that both the signature and the Euler characteristic mod 2 of \(\mathbb{CP}^2\) equal 1.

That the Euler characteristic mod 2 is indeed a bordism invariant of closed 4-manifolds can be seen as follows. It suffices to show that every 4-manifold that bounds a 5-manifold has even Euler characteristic. By Poincaré duality, a closed 5-manifold has vanishing Euler characteristic. Now let \(M\) be the boundary of a 5-manifold \(W\), and consider the Euler characteristic of the closed 5-manifold \(W \cup_M W\). We have \(0 = \chi(W \cup_M W) = 2\chi(W) - \chi(M)\), hence \(\chi(M) = 2\chi(W)\) is even. \(\square\)
By surgery below the middle dimension, any bordism class can be represented by \((M, \nu)\) where the second component of \(\nu\), namely \(c := p_2 \circ \nu\), is a 2-equivalence, inducing an isomorphism \(c_* : \pi_1(M) \xrightarrow{\cong} \pi\). Note also that the first component of \(\nu\) is an orientation of the bundle \(\nu(M) \oplus c^*(L)\) over \(M\), and hence all the circles required in our surgeries have trivial, hence orientable, normal bundle.

**Theorem 2.2.** Let \((M_i, \nu_i)\), for \(i = 1, 2\), be closed 4-manifolds with the same 1-type \((\pi, w)\) and assume that the resulting classifying maps \(c_i : M_i \to B\pi\) are 2-equivalences for \(i = 1, 2\). If \((M_1, \nu_1)\) and \((M_2, \nu_2)\) are \(\xi\)-cobordant then there is a \(\mathbb{CP}^2\)-stable diffeomorphism

\[
M_1 \#^s \mathbb{CP}^2 \#^r \overline{\mathbb{CP}^2} \cong M_2 \#^s \mathbb{CP}^2 \#^r \overline{\mathbb{CP}^2},
\]

for some \(r, \bar{r}, s, \bar{s} \in \mathbb{N}_0\), inducing the isomorphism \((c_2)^{-1} \circ (c_1)_*\) on fundamental groups and preserving the orientations on \(\nu(M_i) \oplus (c_i)^*(L)\).

**Remark 2.3.** In the orientable case \((w = 0)\) we have \(r - \bar{r} = s - \bar{s}\), since the signatures of \(M_1\) and \(M_2\) coincide. For non-orientable \(M_i\) \((w \neq 0)\), as discussed in the introduction the connected sum operation is well-defined without choosing a local orientation, and there is no difference between connected sum with \(\mathbb{CP}^2\) and with \(\overline{\mathbb{CP}^2}\). As a consequence, when \(w \neq 0\) we can write the conclusion with \(\bar{r} = 0 = \bar{s}\). We then must have \(r \equiv s \mod 2\), since the mod 2 Euler characteristics of \(M_1\) and \(M_2\) coincide.

Before proving Theorem 2.2, we explain how Theorem 1.2 from the introduction follows from Theorem 2.2.

**Proof of Theorem 1.2.** Suppose that we are given two closed, connected 4-manifolds \(M_1, M_2\) and 2-equivalences \(c_i : M_i \to B\pi\) with \((c_i)^*(w) = w_i(M_i)\), for \(i = 1, 2\), such that for some choices of fundamental classes, \((c_1)_*, [M_1] = (c_2)_*, [M_2]\) up to \(\pm \text{Aut}(\pi)\). Change \(c_1\) and the sign of \([M_1]\), or equivalently, the orientation of \(\nu(M_1) \oplus (c_1)^*(L)\), so that the images of the fundamental classes coincide. If necessary, add copies of \(\mathbb{CP}^2\) or \(\overline{\mathbb{CP}^2}\) to \(M_1\) until the signatures (or the Euler characteristics mod 2, as appropriate) agree. By Lemma 2.1, the resulting \(\xi\)-manifolds \((M_1, \nu_1)\) and \((M_2, \nu_2)\), are \(\xi\)-bordant, and hence by Theorem 2.2 they are \(\mathbb{CP}^2\)-stably diffeomorphic.

For the converse, for a 4-manifold \(M\) define a map \(f : M \# \mathbb{CP}^2 \to M\) that crushes \(\mathbb{CP}^2 \setminus D^4\) to a point. The map \(f\) is degree one. The classifying map \(c : M \# \mathbb{CP}^2 \to B\pi\) factors through \(f\) since any map \(\mathbb{CP}^2 \to B\pi\) is null homotopic. Therefore \(c_*[M \# \mathbb{CP}^2] = c_*[M] \in H_4(\pi; \mathbb{Z})\).

**Proof of Theorem 2.2.** Let \((W, \tilde{\nu})\) be a compact 5-dimensional \(\xi\)-bordism between the two \(\xi\)-manifolds \((M_1, \tilde{\nu}_1)\) and \((M_2, \tilde{\nu}_2)\). By surgery below the middle dimension on \(W\), we can arrange that \(p_2 \circ \tilde{\nu} : W \to B\pi\) is a 2-equivalence and hence that both inclusions \(M_i \hookrightarrow W\), \(i = 1, 2\), are isomorphisms on fundamental groups. To make sure that the normal bundles to the circles we surger are trivial (so orientable), we use that \(\tilde{\nu}\) pulls back \(w\) to the first Stiefel-Whitney class of \(W\), and that we perform surgery on circles representing elements of \(\pi_1(W)\) that become null homotopic in \(B\pi\).

Pick an ordered Morse function on \(W\), together with a gradient-like vector field, and consider the resulting handle decomposition: \(W\) is built from \(M_1 \times [0, 1]\) by attaching \(k\)-handles for \(k = 0, 1, 2, 3, 4, 5\), in that order. The resulting upper boundary is \(M_2\). Since \(M_1\) and \(W\) are connected, we can cancel the 0- and 5-handles. 
Since the inclusions $M_i \hookrightarrow W$ induce epimorphisms on fundamental groups, we can also cancel the 1- and 4-handles. Both these handle cancelling manoeuvres are well-known and used in the first steps of the proof of the $s$-cobordism theorem e.g. [Wal16, Proposition 5.5.1]. No Whitney moves are required, so this handle cancelling also works in the 5-dimensional cobordism setting. We are left with 2- and 3-handles only.

Next, injectivity of $\pi_1(M_1) \rightarrow \pi_1(W)$ shows that the 2-handles are attached trivially to $M_1$, noting that homotopy implies isotopy for circles in a 4-manifold [Hud72]. Similarly, the 3-handles are attached trivially to $M_2$. As a consequence, the middle level $M \subset W$ between the 2- and the 3-handles is diffeomorphic to both the outcome of 1-surgeries on $M_1$ along trivial circles and the outcome of 1-surgeries on $M_2$ on trivial circles. A 1-surgery on a trivial circle changes $M_i$ by connected sum with an oriented $S^2$-bundle over $S^2$. There are two such bundles since $\pi_1(\text{Diff}(S^2)) = \pi_1(O(3)) = \mathbb{Z}/2$. The twisted bundle occurs if and only if the twisted framing of the normal bundle to the trivial circle is used for the surgery. One can prove, for example using Kirby’s handle calculus, that after connected sum with $\mathbb{CP}^2$ both $S^2 \times S^2$ and $S^2 \times S^2$ become diffeomorphic to $\mathbb{CP}^2 \# \mathbb{CP}^2 \# \mathbb{CP}^2$ [Kir89, Corollaries 4.2 and 4.3], [GS99, p. 151].

The conclusions on the fundamental groups and relative orientations follow because these aspects are controlled through the $\xi$-structure of the bordism. \hfill \Box

**Remark 2.4.** Even the null bordant class exhibits interesting behaviour. A standard construction of a 4-manifold with a given fundamental group $\pi$ and orientation character $w$ takes the boundary of some 5-dimensional manifold thickening $N(K)$ of a 2-complex $K$ with $\pi_1(K) = \pi$ and $w_1(N(K)) = w$. This is the same as doubling a suitable 4-dimensional thickening of $K$ along its boundary. By construction $W_K := \partial N(K)$ is null-bordant over $B\pi$ for any choice of $K$. Thus by Theorem 2.2 the $\mathbb{CP}^2$-stable diffeomorphism class of $W_K$ only depends on the 1-type $(\pi, w)$, and not on the precise choices of $K$ and $N(K)$.

We end this section by outlining Kreck’s original argument [Kre99, Thm. C]. The normal 1-type of a manifold is determined by the data $(\pi, w_1, w_2)$. After adding one copy of $\mathbb{CP}^2$, the universal covering becomes non-spin and then the fibration $\xi: BSO \times B\pi \rightarrow BO$ is the normal 1-type. After adding more copies of $\mathbb{CP}^2$ to $M_1$ or $M_2$ until their signatures agree, our hypothesis gives a bordism between $M_1$ and $M_2$ over this normal 1-type. By subtraction of copies of $S^2 \times D^3$ tubed to the boundary, a cobordism can be improved to an $s$-cobordism, after allowing connected sums of the boundary with copies of $S^2 \times S^2$. Therefore by the stable $s$-cobordism theorem [Qui83], the bordism class of a 4-manifold in $\Omega_1(\xi)$ determines the diffeomorphism class up to further stabilisations with $S^2 \times S^2$. As remarked above, if necessary we may add one more $\mathbb{CP}^2$ to convert all the $S^2 \times S^2$ summands to connected sums of copies of $\mathbb{CP}^2$ and $\mathbb{CP}^2$.

3. Conventions

Let $\pi$ be a group and write $\Lambda := \mathbb{Z}\pi$ for the group ring. For a homomorphism $w: \pi \rightarrow \mathbb{Z}/2$, write $\Lambda^w$ for the abelian group $\Lambda$ considered as a $(\Lambda, \Lambda)$-bimodule, via the usual left action, and with the right action twisted with $w$, so that for $r \in \Lambda$ and $g \in \pi$ we have $r \cdot g = (-1)^w(g)r$. Note that $\Lambda$ and $\Lambda^w$ are isomorphic as left or right modules, but *not* as bimodules.
Let \( R \) be a ring with involution and let \( N \) be an \((R, \Lambda)\)-bimodule. We define another \((R, \Lambda)\)-bimodule \( N^w := N \otimes_\Lambda \Lambda^w \). This is canonically isomorphic to the same left \( R \)-module \( N \) with the right \( \Lambda \) action twisted with \( w \). We consider \( \Lambda \) as a ring with involution using the \textit{untwisted} involution determined by \( g \mapsto g^{-1} \).

For a CW-complex \( X \), or a manifold with a handle decomposition, write \( \pi := \pi_1(X) \). We always assume that \( X \) is connected and comes with a single 0-cell, respectively 0-handle. The cellular or handle chain complex \( C_*(\hat{X}) \cong C_*(X; \Lambda) \) consists of left \( \Lambda \)-modules. Here we pick a base point in order to identify \( C_*(\hat{X}) \) with \( C_*(X; \Lambda) \).

Define the \textit{homology of} \( X \) with \textit{coefficients in} \( N \) as the left \( R \)-module
\[
H_*(X; N) := H_*(N \otimes_\Lambda C_*(X; \Lambda)).
\]
Define the \textit{cohomology of} \( X \) with \textit{coefficients in} \( N \) as the left \( R \)-module
\[
H^*(X; N) := H^*(\text{Hom}_\Lambda(C_*(X; \Lambda), N)),
\]
converting the chain complex into a right \( \Lambda \)-module chain complex using involution on \( \Lambda \), taking \( \text{Hom} \) of right \( \Lambda \)-modules, and using the left \( R \)-module structure of \( N \) for the \( R \)-module structure of the outcome.

Given a chain complex \( C_* \) over a ring with involution \( R \), consisting of left \( R \)-modules, the cochain complex \( C^*: := \text{Hom}_R(C_*, R) \) consists naturally of right modules. Unless explicitly mentioned otherwise, we always convert such a cochain complex into left modules using the involution on \( R \), that is \( r \cdot c = c \pi \).

We will consider closed manifolds to always be connected and smooth unless otherwise explicitly mentioned, and typically of dimension four. For an \( n \)-dimensional closed manifold \( M \) with a handle decomposition, write \( M^2 \) for the dual handle decomposition. The handle chain complex \( C_*(M; \Lambda) \) satisfies \( C_*(M^2; \Lambda) \cong \Lambda^w \otimes_\Lambda C^{n-*}(M; \Lambda) \). That is, the handle chain complex associated to the dual decomposition is equal to the cochain complex of the original decomposition defined using the twisted involution. Let \( d_i : C_i(M; \Lambda) \to C_{i-1}(M; \Lambda) \) be a differential in the chain complex. For emphasis, we write
\[
d^w_i := \text{Id}_{\Lambda^w} \otimes d^i : C^{i-1} \to C^i
\]
to indicate the differentials of the cochain complex obtained using the twisting, which coincide with the differentials of the dual handle decomposition.

A popular choice for coefficient module \( N \) will be \( \mathbb{Z}^w \), the abelian group \( \mathbb{Z} \) considered as a \((\mathbb{Z}, \Lambda)\)-bimodule via the usual left action, and with the right action of \( g \in \pi \) given by multiplication by \((-1)^{w(g)} \). An \( n \)-dimensional closed manifold \( M \), with fundamental group \( \pi \) and orientation character \( w: \pi \to \mathbb{Z}/2 \), has a \textit{twisted fundamental class} \([M] \in H_n(M; \mathbb{Z}^w)\).

\textbf{Remark 3.1.} Observe that the orientation double cover \( \hat{M} \) is canonically oriented. Nevertheless in our context there is still a choice of fundamental class to be made. This arises from the fact that the identification \( H_n(\hat{M}; \mathbb{Z}) \cong H_n(M; \mathbb{Z}[\mathbb{Z}/2]) \) requires a choice of base point. The orientation class of \( \hat{M} \) maps to either \( 1 - T \) or \( T - 1 \) times the sum of the top dimensional handles/cells of \( M \). Evaluating the generator \( T \in \mathbb{Z}/2 \) to \(-1\) yields a homomorphism \( H_n(M; \mathbb{Z}[\mathbb{Z}/2]) \to H_n(M; \mathbb{Z}^w) \) with the image of \([\hat{M}]\) equal to \( \pm 2[M] \). We see that although the double cover is canonically oriented, the twisted fundamental class obtained by this procedure depends on a choice of base point, so there is a choice required.
Twisted Poincaré duality says that taking the cap product with a fundamental class $[M] \in H_n(M;\mathbb{Z}^w)$ gives rise to an isomorphism
\[ - \cap [M] : H^{n-\tau}(M;N^w) \to H_\tau(M;N) \]
for any $r$ and any coefficient bimodule $N$. Since $N^w \cong N$, applying this to $N^w$ yields the other twisted Poincaré duality isomorphism
\[ - \cap [M] : H^{n-r}(M;N) \to H_\tau(M;N^w). \]

4. An extended Hopf sequence

We present an exact sequence, extending the well-known Hopf sequence, for groups $\pi$ that satisfy $H^1(\pi;\Lambda) = 0$, where $\Lambda := \mathbb{Z}\pi$.

Recall from Section 3 that an orientation character $w : \pi \to \mathbb{Z}/2$ endows $\mathbb{Z}^w := \mathbb{Z} \otimes_{\Lambda} \Lambda^w$ with a $(\mathbb{Z},\Lambda)$-bimodule structure. The $\mathbb{Z}^w$-twisted homology of a space $X$ with $\pi_1(X) = \pi$ is defined as the homology of the chain complex $\mathbb{Z}^w \otimes_{\Lambda} C_*(\tilde{X})$.

In the upcoming theorem, write $\pi_2(M)^w := \pi_2(M) \otimes_{\Lambda} \Lambda^w$, where we consider $\pi_2(M)$ as a $\Lambda$-right module using the involution given by $g \mapsto g^{-1}$. Then $\pi_2(M)^w$ is a $(\mathbb{Z},\Lambda)$-bimodule, so we can use it as the coefficients in homology as in Section 3.

**Theorem 4.1.** Let $M$ be a closed 4-manifold with classifying map $c : M \to B\pi$ and orientation character $w : \pi \to \mathbb{Z}/2$. If $H^1(\pi;\Lambda) = 0$ there is an exact sequence
\[
\begin{align*}
H_4(M;\mathbb{Z}^w) &\xrightarrow{c_*} H_4(\pi;\mathbb{Z}^w) \xrightarrow{\partial} H_1(\pi;\pi_2(M)^w) \\
\to H_3(M;\mathbb{Z}^w) &\xrightarrow{c_*} H_3(\pi;\mathbb{Z}^w) \xrightarrow{\partial} H_0(\pi;\pi_2(M)^w) \\
\to H_2(M;\mathbb{Z}^w) &\xrightarrow{c_*} H_2(\pi;\mathbb{Z}^w) \to 0.
\end{align*}
\]

Moreover, the maps $\partial$ only depend on the 2-type $(\pi,w,\pi_2(M),k(M))$.

**Remark 4.2.** When replacing $M$ by its Postnikov 2-type, the sequence in Theorem 4.1 remains exact even without the assumption that $H^1(\pi;\mathbb{Z}\pi) = 0$ by [McC01, Lemma 8.13.27]. The proof of Theorem 4.1 is essentially the same but we repeat it here for the reader’s convenience.

**Proof.** The Leray-Serre spectral sequence applied to the fibration $\tilde{M} \to M \to B\pi$ with homology theory $H_*(\cdot;\mathbb{Z}^w)$ has second page
\[ E^2_{p,q} = H_p(B\pi;H_q(\tilde{M};\mathbb{Z}^w)) = H_p(B\pi;H_q(\tilde{M};\mathbb{Z}) \otimes_{\Lambda} \Lambda^w). \]

Here we consider $H_q(\tilde{M};\mathbb{Z})$ as a right $\Lambda$-module and the fact that $\tilde{M}$ is simply connected means that the $w$-twisting can be taken outside the homology. The spectral sequence converges to $H_{p+q}(M;\mathbb{Z}^w)$.

First, $H_1(\tilde{M};\mathbb{Z}) = 0$, and
\[ H_3(\tilde{M};\mathbb{Z}) \cong H_3(M;\Lambda) \cong H^1(M;\Lambda^w) \cong H^1(M;\Lambda) \cong H^1(\pi;\Lambda) = 0. \]

Thus the $q = 1$ and $q = 3$ rows of the $E^2$ page vanish. Since $H_0(\tilde{M};\mathbb{Z}) \cong \mathbb{Z}$, the $q = 0$ row coincides with the group homology $E^2_{p,0} = H_p(\pi;\mathbb{Z}^w)$. We can write $H_2(\tilde{M};\mathbb{Z}) \cong \pi_2(\tilde{M}) \cong \pi_2(M)$ by the Hurewicz theorem, and the long exact sequence in homotopy groups associated to the fibration above. Therefore the $q = 2$ row reads as
\[ E^2_{p,2} = H_p(\pi;\pi_2(M)^w). \]
Since the $q = 1$ and $q = 3$ lines vanish, the $d^2$ differentials with domains of degree $q \leq 2$ vanish, so we can turn to the $E^3$ page. We have $d^3$ differentials

$$d^3_{3,0}: H_3(\pi; \mathbb{Z}^w) \to H_0(\pi; \pi_2(M^w)),$$

$$d^3_{4,0}: H_4(\pi; \mathbb{Z}^w) \to H_1(\pi; \pi_2(M^w)).$$

It is now a standard procedure to obtain the long exact sequence from the spectral sequence, whose highlights we elucidate. On the 2-line, the terms on the $E^\infty$ page yield a short exact sequence

$$0 \to \ker(d^3_{3,0}) \to H_2(M; \mathbb{Z}^w) \to H_2(\pi; \mathbb{Z}^w) \to 0.$$

On the 3-line, similar considerations give rise to a short exact sequence

$$0 \to \ker d^3_{4,0} \to H_3(M; \mathbb{Z}^w) \to \ker d^3_{3,0} \to 0.$$

Finally the 4-line gives rise to a surjection

$$H_4(M; \mathbb{Z}^w) \to \ker d^3_{4,0} \to 0.$$

Splice these together to yield the desired long exact sequence.

It remains to argue that the $d^3$ differentials in the Leray-Serre spectral sequence only depend on the $k$-invariant of $M$. To see this, consider the map of fibrations

$$\begin{array}{ccc}
\tilde{M} & \to & M \\
\downarrow & & \downarrow \\
K(\pi_2(M), 2) & \to & P_2(M) \\
\end{array}$$

induced by the 3-equivalence from $M$ to its second Postnikov section $P_2(M)$. It induces a map of spectral sequences, and since the map $\tilde{M} \to K(\pi_2(M), 2)$ is an isomorphism on homology in degrees 0, 1, and 2, it follows that the two $d^3$ differentials in the long exact sequences can be identified. Therefore, they only depend on $P_2(M)$, or equivalently, on $(\pi_1(M), \pi_2(M), k(M))$. \hfill \Box

**Corollary 4.3.** Suppose that $H^1(\pi; \Lambda) = 0$ and that $M$ is a closed 4-manifold with 1-type $(\pi, w)$. Then the subgroup generated by $c_*[M] \in H_4(\pi; \mathbb{Z}^w)$ only depends on the 2-type $(\pi, w, \pi_2(M), k(M))$.

**Proof.** The subgroup generated by $c_*[M]$ is precisely the image of $c_*: H_4(M; \mathbb{Z}^w) \to H_4(\pi; \mathbb{Z}^w)$. By Theorem 4.1 the image of $c_*$ is the same as the kernel of the map $\partial: H_4(\pi; \mathbb{Z}^w) \to H_1(\pi; \pi_2(M^w))$. Since the latter only depends on the 2-type of $M$, so does the image of $c_*$. \hfill \Box

In particular, if $H_4(\pi; \mathbb{Z}^w)$ is torsion-free and $H^1(\pi; \Lambda) = 0$, then since the subgroup generated by $c_*[M]$ determines $c_*[M]$ up to sign, Corollary 4.3 implies that the 2-type of $M$ suffices to determine its $\mathbb{CP}^2$-stable diffeomorphism class. Since a group with one end has $H^1(\pi; \Lambda)$, this proves the special case of Theorem A (ii), if in addition we assume that $H_4(\pi; \mathbb{Z}^w)$ is torsion-free. We will also make use of Corollary 4.3 to deduce Theorem A (iii), but we postpone this discussion until the end of Section 7, so that we can collect the facts needed to prove Theorem A in one place.
5. Computing Fourth Homology as an Extension

In this section we prove Proposition 1.10, relating the \( \mathbb{CP}^2 \)-stable classification to the stable isomorphism class of the second homotopy group as an extension.

**Definition 5.1.** For a ring \( R \), we say that two \( R \)-modules \( P \) and \( Q \) are *stably isomorphic*, and write \( P \cong_s Q \), if there exist non-negative integers \( p \) and \( q \) such that \( P \oplus R^p \cong Q \oplus R^q \).

First we will construct an isomorphism using a closed 4-manifold \( M \) with fundamental group \( \pi \) and later recast it in terms of homological algebra to show that it is independent of \( M \). We will use the following description of the extension group.

**Remark 5.2.** Let \( R \) be a ring and let \( N \) and \( L \) be \( R \)-modules. Recall that \( \text{Ext}^1_R(L,N) \) can be described as follows; see e.g. [HS71, Chapter IV.7]. Choose a projective resolution

\[ \cdots \rightarrow P_2 \xrightarrow{p_2} P_1 \xrightarrow{p_1} P_0 \rightarrow L \rightarrow 0 \]

of \( L \) and consider the induced dual sequence

\[ 0 \rightarrow \text{Hom}_R(L,N) \rightarrow \text{Hom}_R(P_0,N) \xrightarrow{(p_1)^*} \text{Hom}_R(P_1,N) \xrightarrow{(p_2)^*} \text{Hom}_R(P_2,N). \]

Then there is a natural isomorphism

\[ \theta : \text{Ext}^1_R(L,N) \rightarrow H_1(\text{Hom}_R(P_*,N)). \]

This isomorphism is given as follows: for an extension \( 0 \rightarrow N \rightarrow E \rightarrow L \rightarrow 0 \), choose a lift \( P_0 \rightarrow L \) to a map \( P_0 \rightarrow E \) and note that the composition \( P_1 \xrightarrow{p_1} P_0 \rightarrow E \) factors through a map \( P_1 \rightarrow N \). This element in \( \text{Hom}_R(P_1,N) \) is a 1-cocycle and represents the image of the extension \( E \) in \( H^1(\text{Hom}_R(P_*,N)) \). Its cohomology class does not depend on the choice of lift.

Let \( \Lambda = \mathbb{Z}[\pi] \), and let \( (D_*,d_2^D) \) be a free resolution of \( \mathbb{Z} \) as a \( \Lambda \)-module, where \( \pi \) acts trivially. Standard dimension shifting [Bro82, Chapter III.7] gives an isomorphism \( H_1(\pi; \mathbb{Z}^w) \cong H_1(\pi; \ker d_2^{D,w}) \). Here the superscript \( w \) denotes twisting the coefficients using \( w : \pi \rightarrow \mathbb{Z}/2 \) as described in Section 3.

Given a closed 4-manifold \( M \) with fundamental group \( \pi \) and orientation character \( w \), we have isomorphisms

\[ H_1(\pi; \ker d_2^{D,w}) \xleftarrow{c_*} H_1(M; \ker d_2^{D,w}) \xrightarrow{PD,\cong} H^3(M; \ker d_2^D), \]

where \( c : M \rightarrow B\pi \) denotes the classifying map and \( PD \) denotes Poincaré duality. Let \( P_2(M) \) be the Postnikov 2-type of \( M \).

**Lemma 5.3.** The induced map \( H^3(P_2(M); \ker d_2^D) \rightarrow H^3(M; \ker d_2^D) \) is an isomorphism.

**Proof.** Since the map \( M \rightarrow P_2(M) \) is 3-connected, the induced map \( H^3(P_2(M); A) \xrightarrow{\cong} H^3(M; A) \) is an isomorphism and the map \( H^3(P_2(M); A) \rightarrow H_3(M; A) \) is injective for any coefficient system \( A \). Using this and \( H^3(M; D_2) \cong H_1(M; D_2) = 0 \), we obtain the following diagram associated with the short exact sequence \( 0 \rightarrow \ker d_2^D \rightarrow \)
$D_2 \to \text{im } d^D_2 \to 0.$

$$
\begin{array}{ccccccccc}
 & & H^2(P_2(M); \text{im } d^D_2) & \xrightarrow{\cong} & H^3(P_2(M); \ker d^D_2) & \xrightarrow{\cong} & H^3(P_2(M); D_2) \\
H^2(M; \text{im } d^D_2) & \xrightarrow{\cong} & H^3(M; \ker d^D_2) & \xrightarrow{} & 0 \\
\end{array}
$$

It follows from commutativity of the left square that the middle vertical map $H^3(P_2(M); \ker d^D_2) \to H^3(M; \ker d^D_2)$ is surjective, and thus an isomorphism. $\square$

By the Hurewicz theorem, $0 = \pi_3(P_2(M)) \to H_3(P_2(M); \mathbb{Z}) \cong H_3(P_2(M); \Lambda)$ is onto, so $H_3(P_2(M); \Lambda)$ is the fundamental lemma of homological algebra, there is a chain map $\ast \to \mathbb{Z}$.

We obtain the chain of isomorphisms

$$
\begin{align*}
(5.4) & \quad H^3(P_2(M); \ker d^D_2) \cong \text{Ext}_1^\Lambda(\text{coker } d^P_3(M), \ker d^D_2), \\
& \text{using the description from Remark 5.2. As we can obtain } P_2(M) \text{ from } M \text{ by attaching cells of dimension } 4 \text{ and higher, we have } d^P_3(M) = \partial M.
\end{align*}
$$

We will now recast this isomorphism using homological algebra. Let $(D_*, d^D_*)$ and $(D'_*, d^{D'}_*)$ be free resolutions of $\mathbb{Z}$ as a $\Lambda$-module with $D'_i$ finitely generated for $i = 0, 1, 2$. Such a resolution exists since the fundamental group of a closed manifold is finitely presented. Using the resolution $D'_i$, we have

$$
(5.5) & \quad H_4(\pi; \mathbb{Z}^w) \cong H_1(\pi; \ker d^{D, w}_2) \\
& \cong H_1(D'_* \otimes \Lambda \ker d^{D, w}_2) \cong H_1(D'_* \otimes \Lambda \ker d^{D, w}_2) \\
& \cong H_1(\text{Hom}_\Lambda(D'_w, \ker d^D_2)).
$$

The last isomorphism uses that $D'_i$ is finitely generated for $i = 0, 1, 2$.

Let $P_* \to \text{coker } d^{D, 2}_{w}$ be a free resolution. As in Remark 5.2, we have an isomorphism

$$\theta: \text{Ext}_1^\Lambda(\text{coker } d^{D, 2}_w, \ker d^D_2) \cong H^1(\text{Hom}_\Lambda(P_*, \ker d^D_2)).$$

By the fundamental lemma of homological algebra, there is a chain map $D^{(2,-*-}_w \to P_*$, unique up to chain homotopy, as follows:

$$
\begin{array}{ccccccccc}
0 & \xrightarrow{} & D'^0_w & \xrightarrow{d^{D', 1}_w} & D'^1_w & \xrightarrow{d^{D', 2}_w} & D'^2_w & \xrightarrow{\text{coker } d^{D', 2}_w} & P_0 \\
& & \cdots & \xrightarrow{} & P_2 & \xrightarrow{} & P_1 & \xrightarrow{} & P_0 \\
\end{array}
$$

This induces a homomorphism

$$\Xi: H^1(\text{Hom}_\Lambda(P_*, \ker d^D_2)) \to H^1(\text{Hom}_\Lambda(D'^{(2,-*-}_w, \ker d^D_2)) \cong H_1(\text{Hom}_\Lambda(D'_w, \ker d^D_2)),$$

so composing this with $\theta$ we obtain a homomorphism $\text{Ext}_1^\Lambda(\text{coker } d^{D, 2}_w, \ker d^D_2) \to H_1(\text{Hom}_\Lambda(D'_w, \ker d^D_2)).$
Lemma 5.6. The homomorphism

$$\Xi : H^1(\text{Hom}_\Lambda(P_\ast, \ker d^2_2)) \to H_1(\text{Hom}_\Lambda(D'_w^\ast, \ker d^2_2))$$

is an isomorphism.

If $D'_w^0 \to D'_w^3 \to D'_w^2$ happens to be exact, in other words if $H^1(\pi; \Lambda) = 0$, then the lemma is straightforward because $D'^{2-1}_w$ is the start of another free resolution of $\ker d^2_{w}$. In general this sequence is not exact. We postpone the proof of the lemma in order to first discuss some of its consequences.

Consider the composition

$$\Psi(D_\ast, D'_\ast) : H_4(\pi; \mathbb{Z}) \cong H_1(\text{Hom}_\Lambda(D'_w^\ast, \ker d^2_2))$$

$$\cong H^1(\text{Hom}_\Lambda(P_\ast, \ker d^2_2))$$

$$\cong \text{Ext}^1_\Lambda(\text{coker } d^2_{w}, \ker d^2_2),$$

using the inverse of the isomorphism $\Xi$ from Lemma 5.6. The composition $\Psi(D_\ast, D'_\ast)$ is natural in $D_\ast$ and $D'_\ast$. This implies the following lemma.

Lemma 5.8. For all chain homotopy equivalences $D_\ast \xrightarrow{f} E_\ast$ and $D'_\ast \xrightarrow{f'} E'_\ast$ of free resolutions, with $D'_\ast, E'_\ast$ finitely generated for $i = 0, 1, 2$, the induced map

$$\text{Ext}^1_\Lambda((f')^*, f_*) : \text{Ext}^1_\Lambda(\text{coker } d^2_{w}, \ker d^2_2) \to \text{Ext}^1_\Lambda(\text{coker } d^{E'}_{w}, \ker d^{E'}_2)$$

is an isomorphism and $\Psi(E_\ast, E'_\ast) = \text{Ext}^1_\Lambda((f')^*, f_*) \circ \Psi(D_\ast, D'_\ast)$.

Lemma 5.8 together with (5.7) implies Proposition 1.9. We will now explain how (5.7) can be identified with (5.5). Let $M$ be a closed, smooth 4-manifold with a 2-equivalence $c : M \to B\pi$ and an element $w \in H^1(\pi; \mathbb{Z}/2)$ such that $c^*(w) = w_1(M)$. Consider a handle decomposition of $M$ with a single 0-handle and a single 4-handle. Let $(C^*_w, d^*_w)$ be the corresponding $\Lambda$-chain complex. Let $(C^*_i, \delta^*_i)$ denote the $\Lambda$-chain complex for the dual handle decomposition. Observe that under the canonical identification of $C^*_i = \Lambda^w \otimes_\Lambda C^{4-i} := C^{4-i}_w$, we have $\delta_i = d^{M}_{i-w}$ and $\delta^*_w = d^{M-w}_{0}$. Hence picking $D_\ast$ and $D'_\ast$, so that $D_i = C^*_i$ and $D'_i = C^w_i$ for $i = 0, 1, 2$, the isomorphism $\Psi(D_\ast, D'_\ast)$ can be identified with (5.5).

Now we begin the promised postponed proof of Lemma 5.6.

Lemma 5.9. Let $D_2 \xrightarrow{d_2} D_1 \xrightarrow{d_1} D_0$ be an exact sequence of finitely generated projective $\Lambda$-modules, and let $f : L \to D^1$ be a $\Lambda$-homomorphism such that $L \xrightarrow{f} D^1 \xrightarrow{d^2} D^2$ is exact. Then

$$D_2 \xrightarrow{d_2} D_1 \xrightarrow{f^*} \text{Hom}_\Lambda(L, \Lambda)$$

is also exact.

Proof. First note that $f^* \circ d_2 = (d^2 \circ f)^*$, and thus $\text{im } d_2 \subseteq \ker f^*$. We need to show that $\ker f^* \subseteq \text{im } d^2$. Dualise $D_2 \xrightarrow{d_2} D_1 \xrightarrow{d_1} D_0$ we have that $d^2 \circ d^1 = 0$. Using this and the hypothesis on $f$ we have a commutative diagram, showing that
both $d^1$ and $f$ factor through $\ker d^2$:

\[
\begin{array}{cccc}
D^0 & \\
\downarrow & \\
\ker d^2 & D^1 & d^2 & D^2. \\
\downarrow & \\
L & f & & \\
\end{array}
\]

Dualise, and identify $D_0$, $D_1$ and $D_2$ with their double duals, to obtain the diagram:

\[
\begin{array}{cccc}
D_2 & d_2 & D_1 & \Hom(\ker d^2, \Lambda) \downarrow \\
\downarrow & & \downarrow & \\
D_0 & & & \Hom(\Lambda, \Lambda).
\end{array}
\]

Since $\Hom(\Lambda, \Lambda)$ is left exact, $\Hom(\ker d^2, \Lambda) \to \Hom(\Lambda, \Lambda)$ is injective as shown. It now follows from the diagram that every element in the kernel of $f^* : D_1 \to \Hom(\Lambda, \Lambda)$ is also in the kernel of $d_1$, and hence by exactness of $D_*$ lies in the image of $d_2$. This shows that $\ker f^* \subseteq \im d^2$ as desired, which completes the proof of the lemma.

The next lemma implies Lemma 5.6 by taking $N := \ker d_2^0$ and $E := D'_w$.

**Lemma 5.10.** Let $E_2 \xrightarrow{d_2} E_1 \xrightarrow{d_1} E_0$ be an exact sequence of finitely generated projective $\Lambda$-modules. Let $N$ be a submodule of a finitely generated free $\Lambda$-module $F$. Let $P_* \to \coker d^2$ be a projective resolution. Then

$$
\Xi : H^1(\Hom(\Lambda(P_*, N)) \to H^1(\Hom(\Lambda(E^{2-\star}, N)) \cong H_1(\Hom(\Lambda(E^\star, N))
$$

is an isomorphism.

**Proof.** By the fundamental lemma of homological algebra, we can assume that $P_1 = E^1 \xrightarrow{d^2} P_0 = E^2$, and obtain a chain map $E^{2-\star} \to P_*$, giving a commutative diagram

\[
\begin{array}{cccc}
E^0 & d^1 & E^1 & d^2 & E^2 & \coker d^2 \\
\uparrow & & \uparrow & & \uparrow & \\
\ldots & P_2 & P_1 & P_0 & & \\
\end{array}
\]

where $\beta$ is defined by the composition $P_2 \to P_1 = E^1$. We will consider three cases: (i) $N = \mathbb{Z}\pi$; (ii) $N$ is a finitely generated free module; and (iii) $N$ is a submodule of a finitely generated free module $F$.

For case (i), we identify $\Hom(\Lambda(E^1, \mathbb{Z}\pi))$ with $E_1$, from which it follows that $H_1(\Hom(\Lambda(E^\star, \mathbb{Z}\pi)) = 0$. By Lemma 5.9 with $D_i = E_i$ for $i = 0, 1, 2$ and $L = P_2$, we deduce that $H^1(\Hom(\Lambda(P_*, \mathbb{Z}\pi))$ is also trivial.

For case (ii), using additivity of both sides under direct sum, the statement follows immediately from case (i).

Finally we consider case (iii). It suffices to show that the kernel of $\beta_N^* \cup \beta_N^*$, shown in the next diagram, agrees with the kernel of $d^1_N^* : \Hom(\Lambda(E^1, N) \to \Hom(\Lambda(E^0, N)$.
Consider the diagram whose rows come from applying $\text{Hom}_A(-, M)$ to the factorisation $d^2 = \beta \circ \alpha$ for $M = N, F$:

\[
\begin{array}{ccc}
    d^1_{N^*} : \text{Hom}_A(E^1, N) & \xrightarrow{\beta^*_{N}} & \text{Hom}_A(P_2, N) \\
    \downarrow & & \downarrow \\
    d^1_{F^*} : \text{Hom}_A(E^1, F) & \xrightarrow{\beta^*_{F}} & \text{Hom}_A(P_2, F)
\end{array}
\]

By case (ii), in the bottom row the kernels of $d^1_{F^*}$, $\text{Hom}_A(E^1, F)$, $\text{Hom}_A(P_2, F)$ both equal the image of $\text{Hom}_A(E^2, F)$, and in particular are equal. Now it follows from an easy diagram chase, using injectivity of the middle vertical map, that the kernels of $\beta^*_{N}$ and $d^1_{N^*}$ also agree, as desired. This completes the proof of case (iii) and therefore of Lemma 5.10. \qed

In order to give a uniform treatment in the following description of iterated Bockstein homomorphisms, define $d^M_0 := \varepsilon : C_0^M \rightarrow C_{-1}^M := \mathbb{Z}$ and write $d^M_i : \mathbb{Z} \rightarrow 0$. Then

\[
\begin{array}{c}
    C_3^M \xrightarrow{d_3^M} C_2^M \xrightarrow{d_2^M} C_1^M \xrightarrow{d_1^M} C_0^M \xrightarrow{d_0^M} C_{-1}^M \rightarrow 0.
\end{array}
\]

is exact at $C_i^M$ for $i \leq 1$. For every $i$ we have a short exact sequence

\[
0 \rightarrow \ker d_i^M \rightarrow C_i^M \xrightarrow{d_i^M} \text{im} d_i^M \rightarrow 0,
\]

which for $i = 0, 1, 2$ by exactness yields a short exact sequence

\[
0 \rightarrow \ker d_i^M \rightarrow C_i^M \xrightarrow{d_i^M} \ker d_{i-1}^M \rightarrow 0.
\]

The isomorphism $H_i(\pi; \mathbb{Z}^w) \rightarrow H_1(\pi; \ker d_2^{M,w})$ from dimension shifting is given by iterating the Bockstein homomorphism $H_{i+1}(\pi; \ker d_2^{M,w}) \rightarrow H_i(\pi; \ker d_2^{M,w})$ for the above short exact sequences twisted by $w$. In order to trace the effect of this isomorphism in Proposition 5.14 below, we have to understand the iterated Bockstein in the following situation.

**Lemma 5.11.** The iterated Bockstein $\beta^3 : H^0(M; \mathbb{Z}) \rightarrow H^3(M; \ker d_2^M)$ for the above short exact sequences sends the class of the augmentation $\varepsilon : C_0^M \cong \Lambda \rightarrow \mathbb{Z}$ to the class of $d_3^M : C_3^M \rightarrow \ker d_2^M$.\]

**Proof.** Let $\beta : H^i(M; \ker d_{i-1}^M) \rightarrow H^{i+1}(M; \ker d_i^M)$ be the Bockstein homomorphism. We claim that $\beta([d_i^M]) = [d_{i+1}^M]$. Then it will follow using this for $i = 0, 1, 2$ that $[\varepsilon] = [d_0^M] \in H^0(M; \ker d_1^M) = H^0(M; \mathbb{Z})$ is sent to $[d_3^M] \in H^3(M; \ker d_2^M)$, as desired. The claim follows from studying the definition of the Bockstein connecting homomorphism via the following diagram.

\[
\begin{array}{c}
    \text{Hom}_A(C_i^M, C_{i+1}^M) \xrightarrow{d_i^M} \text{Hom}_A(C_i^M, \ker d_{i-1}^M) \\
    \downarrow \text{Id}_{C_i^M} \| \text{Id}_{C_i^M} \\
    \text{Hom}_A(C_i^M, \ker d_{i-1}^M) \xrightarrow{- \circ d_i^M} \text{Hom}_A(C_i^M, C_i^M)
\end{array}
\]

Here $d_i^M \in \text{Hom}_A(C_i^M, \ker d_{i-1}^M)$ lifts to $\text{Id}_{C_i^M} \in \text{Hom}_A(C_i^M, C_i^M)$, which is sent to $d_i^M \in \text{Hom}_A(C_i^M, \ker d_{i-1}^M)$, as claimed. \qed
For the proof of Proposition 1.10, we now want to understand \( \pi_2(M) \) as an extension class. As before, let \( M \) be a closed, smooth 4-manifold with a 2-equivalence \( c: M \to B\pi \) and an element \( w \in H^1(\pi; \mathbb{Z}/2) \) such that \( c^*(w) = w_1(M) \). Consider a handle decomposition of \( M \) with a single 0-handle and a single 4-handle. Let \((C_s^*,d^M)\) be the corresponding \( \Lambda \)-chain complex. For a finite, connected 2-complex \( K \) with fundamental group \( \pi \), Hambleton showed [Ham09, Theorem 4.2] that \( \pi_2(M) \) is stably isomorphic as a \( \Lambda \)-module to an extension \( E \) of the form

\[ 0 \to H_2(K;\Lambda) \to E \to H^2(K;\Lambda^w) \to 0. \]

Note that in [Ham09, Theorem 4.2] only the oriented case was considered. To identify the equivalence class of this extension with \( c_*[M] \in H_4(\pi;\mathbb{Z}^w) \), which is the goal of this section, we need the following version of this theorem.

Let \( i: \ker d^M_2 \hookrightarrow C^M_2 \) and \( i': \ker d^M_2 / \im d^M_3 \to \coker d^M_3 \) denote the inclusions and let \( p: \ker d^M_2 \to \ker d^M_2 / \im d^M_3 \) and \( p': C^M_2 \to \coker d^M_3 \) denote the projections.

**Proposition 5.12.** There is a short exact sequence

\[ 0 \to \ker d^M_2 \to C^M_2 \oplus H_2(C^*_s) \xrightarrow{(p',i')} \coker d^M_3 \to 0. \]

**Proof.** Consider the diagram

\[
\begin{array}{ccc}
\ker d^M_2 & \xrightarrow{i} & C^M_2 \\
\downarrow{p} & & \downarrow{p'} \\
H_2(C^*_s) & \xrightarrow{i'} & \coker d^M_3
\end{array}
\]

It is straightforward to check that this square is a pullback as well as a push out. Therefore, we obtain the claimed short exact sequence. \( \square \)

We explain why Proposition 5.12 coincides with [Ham09, Theorem 4.2]. In that reference \( \coker d^M_3 \) is replaced with \( H^2(K;\Lambda^w) \), and \( \ker d^M_2 \) is replaced with \( H_2(K;\Lambda) \), where \( K \) is a finite 2-complex with \( \pi_1(K) = \pi \).

To see why one can make these replacements, we need the following lemma.

**Lemma 5.13.** Let \( K_1, K_2 \) be finite 2-complexes with 2-equivalences \( K_i \to B\pi \) for \( i = 1, 2 \). Then there exist \( p, q \in \mathbb{N}_0 \) such that \( K_1 \vee \bigvee_{i=1}^p S^2 \) and \( K_2 \vee \bigvee_{i=1}^q S^2 \) are homotopy equivalent over \( B\pi \). In particular \( H_2(K_1;\Lambda) \) and \( H_2(K_2;\Lambda) \) are stably isomorphic \( \Lambda \)-modules and so are \( H^2(K_1;\Lambda^w) \) and \( H^2(K_2;\Lambda^w) \).

**Proof.** After collapsing maximal trees in the 1-skeletons of \( K_i \), we can assume that both \( K_i \) have a unique 0-cell. The lemma follows from the existence of Tietze transformations that relate the resulting presentations of the group \( \pi \), by realising the sequence of transformations on the presentation by cellular expansions and collapses. See for example [HAM93, (40)]. \( \square \)

It follows that \( \ker d^M_2 = H_2(M^2;\Lambda) \) is stably isomorphic to \( H_2(K;\Lambda) \). Let \( M^3 \) be the manifold \( M \) endowed with the dual handle decomposition, and let \((C^*_3,d_3)\) be its \( \Lambda \)-module chain complex as before. Fix a choice of (twisted) fundamental class \([M]\) in \( H_4(M;\mathbb{Z}^w) \). Use this choice to identify \( \ker \delta_2 = \ker d^3_{M,w} \) and \( \coker \delta_2 = \coker d^3_{M,w} \). It then follows from Lemma 5.13 that

\[
\ker d^M_2 = H_2(M^2;\Lambda) \cong_s H_2((M^3)^{(2)};\Lambda) = \ker \delta_2 = \ker d^3_{M,w}.\]
\[
\text{coker } d_3^M = \text{coker } d_3^w = H^2((M^2; (2); \Lambda^w) \cong H^2(M(2); \Lambda^w) = \text{coker } d_{M, w}^3.
\]

We can now prove the following proposition, which is the same as Proposition 1.10. Here we use the same choice of \([M]\) that we just fixed.

**Proposition 5.14.** Let \(M\) be a closed 4-manifold with a 2-equivalence \(c: M \to B\pi\) and let \((C_*^M, d_*^M)\) be the chain complex from a handle decomposition of \(M\). Let \(D_*\) be a free resolution of \(\mathbb{Z}\) with \(D_i = C_i^M\) for \(i = 0, 1, 2\) and let \(D'_*\) be a free resolution of \(\mathbb{Z}\) with \(D'_i = C_i^3\) for \(i = 0, 1, 2\). Then the isomorphism \(\Psi(D_*, D'_*)\) takes \(c_*[M] \in H_4(\pi; \mathbb{Z}^w)\) to the equivalence class of the extension from Proposition 5.12:

\[
0 \to \ker d_3^M \to C_2^M \oplus H_2(C_*^M) \to \text{coker } d_3^M \to 0.
\]

**Proof.** We use the identification of \(\Psi(D_*, D'_*)\) with (5.5). Using the description of the extension group from Remark 5.2, the extension from Proposition 5.12 in \(\text{Ext}_A^1(\text{coker } d_3^M, \ker d_3^M)\) is represented by \(d_3^M \in \text{Hom}_A(C_3^M, \ker d_3^M)\). It remains to show that (5.5) sends \(c_*[M]\) to the class \([d_3^M]\) in \(\text{Ext}_A^1(\text{coker } d_3^M, \ker d_2^M)\).

Consider the diagram

\[
\begin{array}{c}
H_4(M; \mathbb{Z}^w) \xrightarrow{\epsilon_*} H^0(M; \mathbb{Z}) \quad \gamma^3 \quad H^3(M; \ker d_2^M) \\
\text{ } \searrow \quad \downarrow PD \quad \text{ } \downarrow PD \\
H_4(\pi; \mathbb{Z}^w) \xrightarrow{\epsilon_*} H_1(\pi; \ker d_2^* \subseteq H_1(\pi; \ker d_2^M).
\end{array}
\]

The square commutes by naturality of Poincaré duality in the coefficients. Under Poincaré duality the fundamental class \([M] \in H_4(M; \mathbb{Z}^w)\) is mapped to the class in \(H^0(M; \mathbb{Z})\) represented by the augmentation \(\epsilon: C_0^M \cong A \to \mathbb{Z}\). By Lemma 5.11, \(\gamma^3\) maps \([\epsilon]\) to \([d_3^M]\) in \(H^3(M; \ker d_2^M)\). So \([M]\) is sent by the top route to \([d_3^M]\). On the other hand the bottom-then-up route \(H_4(\pi; \mathbb{Z}^w) \to H_4(\pi; \mathbb{Z}^w)\) is the first three isomorphisms of (5.5). So by commutativity these send \(c_*[M]\) to \([d_3^M]\). Finally, since \(P_2(M)\) is obtained from \(M\) by attaching cells of dimension 4 and higher, \([d_3^M]\) in \(H^3(P_2(M); \ker d_2^M)\) is a pre-image of \([d_3^M]\) in \(H^3(M; \ker d_2^M)\). It follows that \(c_*[M]\) is mapped under (5.5) to the extension represented by \([d_3^M]\), as desired. \(\square\)

6. Detecting the Extension Class

This section is entirely algebraic. Let \(h\text{Ch}_2(\pi)\) denote the category whose objects are free \(A\)-chain complexes \(C_*\) concentrated in non-negative degrees such that \(H_n(C_*) = 0\) for \(n \neq 0, 2\), together with a fixed identification \(H_0(C_*) = \mathbb{Z}\), and whose morphisms are chain maps that induce the identity on \(H_0\), considered up to chain homotopy. Let \(\Lambda^w[2]\) denote the chain complex given by the based free \(A\)-module \(\Lambda^w\) concentrated in degree 2. We call two chain complexes \(C_*, C'_*\) stably isomorphic if there exists \(p, q\) such that \(C_* \oplus \Lambda^w[2]\) and \(C'_* \oplus \Lambda^w[2]\) are isomorphic in \(h\text{Ch}_2(\pi)\), meaning that they are chain homotopy equivalent. We denote the set of stable isomorphisms classes by \(s\text{Ch}_2(\pi)\).

For the rest of this section fix a free resolution \((C_*, d_*)\) of \(\mathbb{Z}\) as a \(A\)-module with \(C_*\) finitely generated for \(\ast = 0, 1, 2\). Also fix a complex

\[
\cdots \to B_4 \xrightarrow{b_4} B_3 \xrightarrow{b_3} B_2.
\]
of free $\Lambda$-modules that is exact at $B_n$ for $n \geq 3$, with $B_2$ and $B_3$ finitely generated. Furthermore, assume that the dual complex $B^2 \xrightarrow{b^3} B^3 \xrightarrow{b^4} B^4 \to \cdots$ is exact at $B^3$, or equivalently that $\text{Ext}^1_{\Lambda}(\text{coker } b_3, \Lambda) = 0$.

Next we define a map $\Theta: \text{Ext}^1_{\Lambda}(\text{coker } b_3, \ker d_2) \to \text{sCh}_2(\pi)$. Recall from Remark 5.2 that any element of $\text{Ext}^1_{\Lambda}(\text{coker } b_3, \ker d_2)$ can be represented by a map $f: B_3 \to \ker d_2$ with $f \circ b_4 = 0$. For such a map, let $C_f$ be the $\Lambda$-chain complex

$$\cdots \xrightarrow{b_4} B_4 \xrightarrow{(f, b_3)^T} B_3 \oplus B_2 \xrightarrow{(d_2, 0)} C_2 \oplus B_1 \xrightarrow{d_1} C_1 \to 0.$$  

Note that $H_*(C_f) = 0$ for $* \neq 0, 2$ and that $H_0(C_f) = \mathbb{Z}$, thus $C_f$ is an element in $\text{sCh}_2(\pi)$. This is our candidate for $\Theta([f])$. We need to check that it is well-defined.

**Remark 6.1.** As in Proposition 5.12, there is a short exact sequence

$$(6.2) \quad 0 \to \text{ker } d_2 \oplus B_2 \to H_2(C_f) \oplus C_2 \oplus B_2 \to \text{coker}(f, b_3)^T \to 0.$$  

In the proof of Theorem 6.6 we show that $\text{coker}(f, b_3)^T$ is isomorphic to $C_2 \oplus \text{coker } b_3$. Thus stably $H_2(C_f)$ represents an element of $\text{Ext}^1_{\Lambda}(\text{coker } b_3, \ker d_2)$. Moreover, using the free resolution

$$B_4 \to B_3 \xrightarrow{(0, b_3)^T} C_2 \oplus B_2 \to C_2 \oplus \text{coker } b_3,$$

it can be shown that $(6.2)$, considered as an element of $\text{Ext}^1_{\Lambda}(C_2 \oplus \text{coker } b_3, \ker d_2 \oplus B_2)$, is represented by $(f, b_3)^T: B_3 \to \ker d_2 \oplus B_2$, or equivalently by $(f, 0)^T: B_3 \to \ker d_2 \oplus B_2$. We will not make use of this fact.

**Lemma 6.3.** Suppose that two maps $f, g: B_3 \to \ker d_2$ differ by a coboundary $B_3 \xrightarrow{b_3} B_2 \xrightarrow{h} \ker d_2$, so represent the same extension class in $\text{Ext}^1_{\Lambda}(\text{coker } b_3, \ker d_2)$. Then $[C_f] = [C_g] \in \text{sCh}_2(\pi)$.

**Proof.** Two maps $f, g: B_3 \to \ker d_2$ represent the same extension class if and only if $f - g = h \circ b_3$, for some $h: B_2 \to \ker d_2 \subseteq C_2$. We then have the following chain isomorphism.

$$\cdots \xrightarrow{\text{Id}} B_3 \xrightarrow{(f, b_3)^T} C_2 \oplus B_2 \xrightarrow{(d_2, 0)} C_1 \xrightarrow{d_1} C_0 \xrightarrow{\text{Id}}$$  

In particular, $[C_f] = [C_g] \in \text{sCh}_2(\pi)$. □

Thus we obtain a well-defined map as follows:

$$\Theta: \text{Ext}^1_{\Lambda}(\text{coker } b_3, \ker d_2) \to \text{sCh}_2(\pi) \quad [f] \mapsto [C_f].$$  

Our next aim is to find a suitable quotient of the domain that converts this map into an injection. The inclusion $\text{coker } b_3 \to \text{coker } b_3 \oplus \Lambda$ induces an isomorphism (cf. Lemma 5.8)

$$\text{Ext}^1_{\Lambda}(\text{coker } b_3, \ker d_2) \xrightarrow{\text{Ext}^1_{\Lambda}(\text{coker } b_3 \oplus \Lambda, \ker d_2),}$$

and hence any automorphism of $\text{coker } b_3 \oplus \Lambda^n$ acts on $\text{Ext}^1_{\Lambda}(\text{coker } b_3, \ker d_2)$.

**Lemma 6.5.** The map $\Theta$ from (6.4) is invariant under the action of $\alpha \in \text{Aut}(\text{coker } b_3 \oplus \Lambda^n)$ on $\text{Ext}^1_{\Lambda}(\text{coker } b_3, \ker d_2)$, that is $\Theta(\alpha \cdot [f]) = \Theta([f])$. 

Proof. Let \( \alpha : \text{coker } B_3 \oplus \Lambda^n \to \text{coker } B_3 \oplus \Lambda^n \) be a stable automorphism of \( \text{coker } B_3 \). This can be lifted to a chain map

\[
\cdots \to B_3 \to B_2 \oplus \Lambda^n \to \text{coker } B_3 \oplus \Lambda^n \to \cdots
\]

\[
\text{ker } \alpha \to \text{coker } B_3 \oplus \Lambda^n
\]

since the top row is projective and the bottom row is exact. The action of \( \alpha \) on an extension represented by \( f : B_3 \to \text{ker } d_2 \) is given by precomposition with \( \alpha_3 : B_3 \to B_3 \). We have the following chain map:

\[
\cdots \to B_3 \to \text{coker } B_3 \oplus \Lambda^n \to \cdots
\]

\[
\to \text{ker } \alpha \to \text{coker } B_3 \oplus \Lambda^n
\]

It remains to prove that the chain map above induces an isomorphism on second homology, which since it is chain map between bounded chain complexes of f.g. projective module, implies that it is a chain homotopy equivalence.

To see surjectivity on second homology, consider a pair \( (x, y, \lambda) \in C_2 \oplus B_2 \oplus \Lambda^n \) with \( x \in \text{ker } d_2 \). Since \( \alpha \) is an isomorphism, there exists \( (y', \lambda') \in B_2 \oplus \Lambda^n \) and \( a \in B_3 \) with \( (y, \lambda) = (b_3(a), 0) + \alpha_2(y', \lambda') \). In \( H_2(C_f \oplus \Lambda^n[2]) \), i.e. the homology of the bottom row, we have

\[
[(x, y, \lambda)] = [x, b_3(a), 0] + [0, \alpha_2(y', \lambda')] = [x - f(a), \alpha_2(y', \lambda')],
\]

which is the image of \( (x - f(a), y', \lambda') \) under the above chain map.

Now, to prove injectivity on second homology, consider a pair \( (x, y, \lambda) \in C_2 \oplus B_2 \oplus \Lambda^n \) with \( x \in \text{ker } d_2 \), and assume that there exists \( a \in B_3 \) with \( f(a) = x \) and \( (b_3(a), 0) = \alpha_2(y, \lambda) \). Again since \( \alpha \) is an isomorphism, this implies that \( \lambda = 0 \) and that there exists \( a' \in B_3 \) with \( b_3(a') = y \). We have

\[
(b_3(a), 0) = \alpha_2(y, 0) = \alpha_2(b_3(a'), 0) = (b_3 \circ \alpha_3(a'), 0) \in B_2 \oplus \Lambda^n.
\]

Since \( B_3 \xrightarrow{b_3} B_3 \xrightarrow{b_3} B_2 \) is exact at \( B_3 \), there is an element \( c \in B_4 \) with \( b_4(c) = a - \alpha_3(a') \). Since \( f \circ b_4 = 0 \), we have that \( x = f(a) = f(b_4(c) + \alpha_3(a') = f(\alpha_3(a')) \).

Hence \( (x, y, 0) = ((f \circ \alpha_3)(a'), b_3(a'), 0) \) and the element \( (x, y, 0) \) is trivial in second homology as desired. \( \square \)

Let \( \text{sAut}(\text{coker } b_3) \) denote the group of stable automorphisms of \( \text{coker } b_3 \) as above. We can now state the main theorem of this section.

**Theorem 6.6.** The assignment \( \Theta \) from (6.4) descends to an injective map

\[
\Theta : \text{Ext}^1_{\Lambda}(\text{coker } b_3, \text{ker } d_2) / \text{sAut}(\text{coker } b_3) \to \text{SCh}_2(\pi).
\]

**Proof.** By Lemma 6.5, \( \Theta \) is well-defined on the quotient by \( \text{sAut}(\text{coker } b_3) \). Let \( f, g : B_3 \to \text{ker } d_2 \) represent two extensions, and suppose that their images in
sCh$_2(\pi)$ agree. Then there is a chain map

\[
\begin{array}{cccccccccc}
B_3 & \xrightarrow{(f,b_3,0)^T} & C_2 \oplus B_2 \oplus \Lambda^n & \xrightarrow{(d_2,0,0)} & C_1 & \xrightarrow{d_1} & C_0 & \xrightarrow{} & \mathbb{Z} \\
\downarrow h_3 & & \downarrow h_2 & & \downarrow h_1 & & \downarrow h_0 & & \downarrow \text{Id} \\
B_3 & \xrightarrow{(g,b_3,0)^T} & C_2 \oplus B_2 \oplus \Lambda^n & \xrightarrow{(d_2,0,0)} & C_1 & \xrightarrow{d_1} & C_0 & \xrightarrow{} & \mathbb{Z}
\end{array}
\]

that induces an isomorphism on second homology. We can assume that the chain map $h_\ast$ is the identity on $C_1$ and $C_0$.

Consider the diagram with exact rows:

\[
\begin{array}{cccccccccc}
0 & \xrightarrow{} & \ker(d_2,0,0)/\text{im}(f,b_3,0)^T & \xrightarrow{(h_2)_\ast} & \text{coker}(f,b_3,0)^T \xrightarrow{(d_2,0,0)} \text{im}(d_2,0,0) & \xrightarrow{} & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \xrightarrow{} & \ker(d_2,0,0)/\text{im}(g,b_3,0)^T & \xrightarrow{(h_2)_\ast} & \text{coker}(g,b_3,0)^T \xrightarrow{(d_2,0,0)} \text{im}(d_2,0,0) & \xrightarrow{} & 0.
\end{array}
\]

Since $h_2$ induces an isomorphism on second homology, the map $\text{coker}(f,b_3,0)^T \rightarrow \text{coker}(g,b_3,0)^T$ induced by $h_2$ is an isomorphism by the five lemma. Use the facts that the composition $B_1 \rightarrow B_3 \xrightarrow{f} C_2$ is trivial and the sequence $B^2 \rightarrow B^3 \rightarrow B^4$ is exact, to see that the dual of $f$ lifts to a map $\hat{f} : C^2 \rightarrow B^2$, as in the next diagram.

\[
\begin{array}{cccc}
C^2 & \xrightarrow{f^*} & B^2 \\
\downarrow & & \downarrow \\
\hat{f}^* & \xrightarrow{\hat{f}^*} & B^3 \\
\downarrow & & \downarrow \\
B^3 & \xrightarrow{b_3} & B^4
\end{array}
\]

Dualise again to deduce that $f : B_3 \rightarrow C_2$ factors as $B_3 \xrightarrow{b_3} B_2 \xrightarrow{\hat{f}} C_2$. This gives rise to a commutative square

\[
\begin{array}{cccc}
B_3 & \xrightarrow{\text{Id}} & B_3 \\
\downarrow (0,b_3)^T & & \downarrow \left( \begin{array}{c} \text{Id} \\ 0 \text{Id} \end{array} \right) \\
C_2 \oplus B_2 & \xrightarrow{(f,b_3)^T} & C_2 \oplus B_2
\end{array}
\]

that induces an isomorphism $C_2 \oplus \text{coker} b_3 \cong \text{coker}(0,b_3)^T \rightarrow \text{coker}(f,b_3)^T$.

Add the identity on $\Lambda^n$ to obtain an isomorphism

\[
C_2 \oplus \text{coker} b_3 \oplus \Lambda^n \cong \text{coker}(f,b_3,0)^T.
\]

Similarly, we obtain an isomorphism $C_2 \oplus \text{coker} b_3 \oplus \Lambda^n \cong \text{coker}(g,b_3,0)^T$. 
In the next diagram we show a composition of these maps that give a stable automorphism of $\text{coker } b_3$ and its resolution.

\[
\begin{array}{c}
  \cdots \rightarrow B_3 \overset{(0,b_3,0)^T}{\rightarrow} C_2 \oplus B_2 \oplus \Lambda^n \rightarrow C_2 \oplus \text{coker } b_3 \oplus \Lambda^n \rightarrow 0 \\
  \downarrow \text{Id} \quad \downarrow \text{(Id } \tilde{f} \text{, 0) } \quad \downarrow \text{(Id } \tilde{f} \text{, 0) } \quad \downarrow \text{Id} \\
  \cdots \rightarrow B_3 \overset{(f,b_3,0)^T}{\rightarrow} C_2 \oplus B_2 \oplus \Lambda^n \rightarrow \text{coker}(f, b_3, 0)^T \rightarrow 0 \\
  \downarrow h_3 \quad \downarrow h_2 \\
  \cdots \rightarrow B_3 \overset{(g,b_3,0)^T}{\rightarrow} C_2 \oplus B_2 \oplus \Lambda^n \rightarrow \text{coker}(g, b_3, 0)^T \rightarrow 0 \\
  \downarrow \text{Id} \quad \downarrow \text{(Id } \tilde{g} \text{, 0) } \quad \downarrow \text{(Id } \tilde{g} \text{, 0) } \quad \downarrow \text{Id} \\
  \cdots \rightarrow B_3 \overset{(0,b_3,0)^T}{\rightarrow} C_2 \oplus B_2 \oplus \Lambda^n \rightarrow C_2 \oplus \text{coker } b_3 \oplus \Lambda^n \rightarrow 0
\end{array}
\]

The induced action on $B_3$ is via $h_3$, so the stable automorphism shown act on a map $f: B_3 \rightarrow \ker d_2$ representing an element of $\text{Ext}^1_\Lambda(\text{coker } b_3, \ker d_2)$ by pre-composition with $h_3$, that is $f \circ h_3: B_3 \rightarrow \ker d_2$.

To recap, we started with the chain map $h_*$ arising from the assumption of two extensions having equal image in $\text{sCh}_2(\pi)$, and we obtained an automorphism of $\text{coker } b_3$, that acts on a representative map $B_3 \rightarrow \ker d_2$ in $\text{Ext}^1_\Lambda(\text{coker } b_3, \ker d_2)$ by pre-composition with $h_3$. To complete the proof, we have to show that $g \circ h_3$ and $f$ represent the same class in $\text{Ext}^1_\Lambda(\text{coker } b_3, \ker d_2)$.

Recall the definition of $\tilde{f}: B_2 \rightarrow C_2$ from above, and consider the composition

\[ F: B_2 \overset{(\tilde{f}, \text{Id}, 0)^T}{\rightarrow} C_2 \oplus B_2 \oplus \Lambda^n \overset{h_2}{\rightarrow} C_2 \oplus B_2 \oplus \Lambda^n \overset{\text{pr}_1}{\rightarrow} C_2. \]

Now consider the commutative diagram

\[
\begin{array}{cccccc}
  & B_3 & \overset{\text{Id}}{\rightarrow} & B_3 & \overset{h_3}{\rightarrow} & B_3 & \overset{\text{Id}}{\rightarrow} B_3 \\
  & b_3 \downarrow & \downarrow (f,b_3,0)^T & \downarrow (g,b_3,0)^T & \downarrow g & \\
  B_2 & \overset{(\tilde{f}, \text{Id}, 0)^T}{\rightarrow} C_2 \oplus B_2 \oplus \Lambda^n & \overset{h_2}{\rightarrow} C_2 \oplus B_2 \oplus \Lambda^n & \overset{\text{pr}_1}{\rightarrow} C_2 & \\
  & (d_2,0,0) \downarrow & \downarrow (d_2,0,0) & \downarrow d_2 & \\
  & C_4 & \overset{\text{Id}}{\rightarrow} C_1 & \overset{\text{Id}}{\rightarrow} C_1 & \\
\end{array}
\]

Commutativity of the three top squares shows that $g \circ h_3 = F \circ b_3$. Commutativity of the lower two squares pre-composed with $(\tilde{f}, \text{Id}, 0)^T: B_2 \rightarrow C_2 \oplus B_2 \oplus \Lambda^n$ proves that $d_2 \circ F = d_2 \circ \tilde{f}$. It follows from the first statement that $g \circ h_3 - f = F \circ b_3 - f$, which equals $(F - \tilde{f}) \circ b_3: B_3 \rightarrow C_2$ since $f = \tilde{f} \circ b_3$. This is in fact a map $(F - \tilde{f}) \circ b_3: B_3 \rightarrow \ker d_2$ since $d_2 \circ F = d_2 \circ \tilde{f}$. Thus $g \circ h_3 - f: B_3 \rightarrow \ker d_2$ factors through $B_2$ and hence represents the trivial extension class.

Next we check that the map $\Theta: \text{Ext}^1_\Lambda(\text{coker } b_3, \ker d_2) \rightarrow \text{sCh}_2(\pi)$ from (6.4) does not depend on the choice of resolution $C_*$. Let $(C'_*, d'_*)$ be another free resolution of $\mathbb{Z}$ as a $\Lambda$-module with $C'_i$ finitely generated for $i = 0, 1, 2$ and let $\alpha_*: C_* \rightarrow C'_*$ be a chain homotopy equivalence over $\mathbb{Z}$. Then $\alpha_*$ induces a map $a: \ker d_2 \rightarrow \ker d'_2$ given by restricting $\alpha_2$. 

\[ \square \]
Lemma 6.7. The diagram

\[
\begin{array}{ccc}
\Ext^1_A(\ker b_3, \ker d_2) & \xrightarrow{\Theta} & \sCh_2(\pi) \\
\downarrow{\alpha} & & \\
\Ext^1_A(\ker b_3, \ker d'_2)
\end{array}
\]

commutes.

Proof. First consider the case that \(\alpha\) restricted to degrees 0, 1, 2 is a chain homotopy equivalence. Then

\[
\begin{array}{c}
\cdots \to B_3 \xrightarrow{(f,b_3)^T} C_2 \oplus B_2 \xrightarrow{(d_2,0)} C_1 \xrightarrow{d_1} C_0 \\
\downarrow{\Id} \quad \downarrow{\alpha_2 \oplus \Id} \quad \downarrow{\alpha_1} \quad \downarrow{\alpha_0} \\
\cdots \to B_3 \xrightarrow{(a_2 \circ f,b_3)^T} C'_2 \oplus B_2 \xrightarrow{(d'_2,0)} C'_1 \xrightarrow{d'_1} C'_0
\end{array}
\]

is a chain homotopy equivalence and \(\Theta([f]) = \Theta(\alpha_*[f])\).

Next we will now reduce the lemma to the case \(C_* = C'_*\). Let \((F_i \xrightarrow{\Id} F_i)[i]\) denote the chain complex \(F_i \xrightarrow{\Id} F_i\) concentrated in degrees \(i\) and \(i+1\). Applying Schanuel’s lemma [Sta20, Tag 0003], [Bro82, Lemma VIII.4.2] inductively, for any two free resolutions \(C_*\), \(C'_*\) of \(\mathbb{Z}\), there are free \(\Lambda\)-modules \(F_i\) and \(F'_i\) such that \(C_* \oplus \bigoplus_{i \in \mathbb{N}_0} (F_i \xrightarrow{\Id} F_i)[i]\) and \(C'_* \oplus \bigoplus_{i \in \mathbb{N}_0} (F'_i \xrightarrow{\Id} F'_i)[i]\) are isomorphic over \(\mathbb{Z}\). The inclusion of \(C'_* \oplus (F'_2 \xrightarrow{\Id} F'_2)[2]\) into \(C'_* \oplus \bigoplus_{i \in \mathbb{N}_0} (F'_i \xrightarrow{\Id} F'_i)[i]\) as well as the projection of \(C_* \oplus \bigoplus_{i \in \mathbb{N}_0} (F_i \xrightarrow{\Id} F_i)[i]\) onto \(C_* \oplus (F_2 \xrightarrow{\Id} F_2)[2]\) are chain homotopy equivalences that remain chain homotopy equivalences upon restricting to degrees 0, 1, 2. It follows from the first paragraph that there is a chain homotopy equivalence \(\beta: C'_* \oplus (F'_2 \xrightarrow{\Id} F'_2)[2] \to C_* \oplus (F_2 \xrightarrow{\Id} F_2)[2]\) over \(\mathbb{Z}\) such that, taking \(b: \ker d'_2 \to \ker d_2\) to be the restriction of \(\beta_2\), we have \(\Theta = \Theta \circ b_*\).

Next we want to relate this to the chain complexes \(C_*\) and \(C'_*\) before stabilisation. The inclusion \(C_* \to C_* \oplus (F_2 \xrightarrow{\Id} F_2)[2]\) is a chain homotopy equivalence whose induced map on kernels is the inclusion \(\ker d_2 \to \ker d_2 \oplus F_2\) and similarly for \(C'_*\). By definition,

\[
\begin{array}{ccc}
\cdots \to B_3 \xrightarrow{(f_0,b_3)^T} C_2 \oplus B_2 \xrightarrow{(d_2,0,0)} C_1 \xrightarrow{d_1} C_0 \\
\cdots \to B_3 \xrightarrow{(f,b_3)^T} C_2 \oplus B_2 \xrightarrow{(d_2,0)} C_1 \xrightarrow{d_1} C_0
\end{array}
\]

represent the same element in \(\sCh_2(\pi)\). Thus composing \(C'_* \to C'_* \oplus (F'_2 \xrightarrow{\Id} F'_2)[2] \to C_* \oplus (F_2 \xrightarrow{\Id} F_2) \to C_*\) gives a chain homotopy equivalence \(\beta^!: C'_* \to C_*\) over \(\mathbb{Z}\) with induced map \(\beta^!\) such that \(\Theta = \Theta \circ b_*\).

Given any chain homotopy equivalence \(\alpha: C_* \to C'_*\) over \(\mathbb{Z}\) we can consider the composition \(\beta^! \circ \alpha\). Since \(\Theta = \Theta \circ b_*\) for \(\beta^!\), it suffices to show that \(\Theta = \Theta \circ b_* \circ \alpha\). So we may restrict to the case \(C'_* = C_*\).

Let \(\alpha_*: C_* \to C_*\) be a chain homotopy equivalence over \(\mathbb{Z}\) and let \(\alpha: \ker d_2 \to \ker d_2\) be the restriction of \(\alpha_2\). As \(\alpha_*\) is a chain homotopy equivalence over \(\mathbb{Z}\), it is chain homotopic to the identity. Let \(H_*: C_* \to C_{*+1}\) be such that \(\Id - \alpha_* = \)
Then the diagram on the left commutes. Thus also the diagram on the right commutes.

On the right the columns are short exact. Apply \( \text{Ext}^* \) to obtain the following diagram.

\[
\cdots \xrightarrow{\alpha} \text{Hom}_\Lambda(\text{coker } b_3, \text{im } d_2) \xrightarrow{1} \text{Ext}^1_\Lambda(\text{coker } b_3, \text{ker } d_2) \xrightarrow{\alpha} 0
\]

Here we use that \( \text{Ext}^1_\Lambda(\text{coker } b_3, C_2) = 0 \), which since \( C_2 \) is free follows from the assumption on \( b_3 \) that \( \text{Ext}^1_\Lambda(\text{coker } b_3, \Lambda) = 0 \). In particular, \( \alpha_* : \text{Ext}^1_\Lambda(\text{coker } b_3, \text{ker } d_2) \to \text{Ext}^1_\Lambda(\text{coker } b_3, \text{ker } d_2) \) is the identity.

Now, to apply this to the \( \mathbb{C}P^2 \)-stable classification of 4-manifolds, we need to investigate the action of \( \text{sAut}(\text{coker } b_3) \) on the extension classes for some families of 1-types. More precisely, we choose \( b_3 \) to be \( d^2_w \), the dual of \( d_2 \) twisted by \( w : \pi \to \mathbb{Z}/2 \).

**Lemma 6.8.** Assume that \( H^1(\pi; \Lambda) = 0 \) and \( \pi \) is infinite. Then \( \text{sAut}(\text{coker } d^2_w) \) acts on \( \text{Ext}^1_\Lambda(\text{coker } d^2_w, \text{ker } d_2) \) by multiplication by \( \pm 1 \).

**Proof.** Since \( \pi \) is infinite, \( H^0(\pi; \Lambda) = 0 \). As \( \Lambda \) is isomorphic to \( \Lambda^w \) as a right \( \Lambda \)-module, we also have \( H^0(\pi; \Lambda^w) = H^1(\pi; \Lambda^w) = 0 \). Hence the sequence

\[
0 \to C^0 \xrightarrow{d^1_w} C^1 \xrightarrow{(d^2_w, 0)^T} C^2 \oplus \Lambda^n \to \text{coker } d^2_w \oplus \Lambda^n \to 0
\]

is exact. Thus every stable automorphism \( \alpha \) of \( \text{coker } d^2_w \) lifts to a chain map \( \alpha^* \) as follows.

\[
\begin{array}{ccc}
C^0 & \xrightarrow{d^1_w} & C^1 \\
\alpha^0 & & \alpha^1 \\
C^0 & \xrightarrow{d^1_w} & C^1 \\
\end{array}
\begin{array}{ccc}
& (d^2_w, 0)^T & \\
\alpha^2 & \alpha & \\
& (d^2_w, 0)^T & \\
\end{array}
\begin{array}{ccc}
C^2 \oplus \Lambda^n & \xrightarrow{\alpha} & \text{coker } d^2_w \oplus \Lambda^n \\
\end{array}
\]

The action of \( \alpha \) on \( \text{Ext}^1_\Lambda(\text{coker } d^2_w, \text{ker } d_2) \) is given by pre-composition with \( \alpha^1 \). Let \( \beta^* \) be a lift of \( \alpha^{-1} \) to a chain map. Let \( H^*: C^* \to C^{*-1} \) be a chain homotopy from \( \beta^* \circ \alpha^* \) to \( \text{id} \). In particular, \( \beta^0 \circ \alpha^0 - \text{id} = H^1 \circ d^1_w \). Take duals and twist with \( w \) to obtain \( \alpha_0 \circ \beta_0 - \text{id} = d_1 \circ H_1 \). Hence \( \alpha_0 \circ \beta_0 \) induces the identity on \( \text{coker } d_1 \cong \mathbb{Z} \) and thus \( \alpha_0 \) induces multiplication by plus or minus one on \( \text{coker } d_1 \).
Dualise $\alpha^*$ and twist with $w$ again to obtain the following diagram, where the maps $\alpha_i$ are the maps dual to $\alpha^i$.

$$
\begin{array}{c}
\begin{array}{c}
C_0 \\
\downarrow d_1 \\
C_1 \\
\downarrow (d_2,0) \\
C_2 \oplus \Lambda^n
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
C_0 \\
\downarrow d_1 \\
G_0 \\
\downarrow G_1 \\
(d_3,0)
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
C_1 \\
\downarrow (d_2,0) \\
C_2 \oplus \Lambda^n
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
\alpha_0 \\
\alpha_1 \\
\alpha_2
\end{array}
\end{array}
$$

Since $\alpha_0$ induces multiplication by plus or minus one on $\text{coker } d_1$, $\alpha_0 \pm \text{Id}: C_0 \to C_0$ factors through $d_1$. That is, there exists a homomorphism $G_0: C_0 \to C_1$ with $d_1 \circ G_0 = \alpha_0 \pm \text{Id}$. This implies $d_1 \circ ((\alpha_1 \pm \text{Id}) - G_0 \circ d_1) = 0$, so there exists $G_1: C_1 \to C_2 \oplus \Lambda^n$ with $\alpha_1 \pm \text{Id} = G_0 \circ d_1 + (d_2,0) \circ G_1$.

Take duals and twist by $w$ one last time to obtain $\alpha^1 \pm \text{Id} = d^1_w \circ G^0 + G^1 \circ d^2_w$, where $G^i$ is the map dual to $G_i$ for $i = 0, 1$.

Now let $f: C^1 \to \ker d_2$ represent an extension $\text{Ext}^1_\Lambda(\text{coker } d^2_w, \ker d_2)$. In particular, $f \circ d^2_w = 0$ and thus

$$
\alpha_*[f] = [f \circ \alpha^1] = [\mp f + f \circ G^1 \circ d^2_w] = [\mp f].
$$

Hence $\alpha$ acts by multiplication by $\pm 1$ on $\text{Ext}^1_\Lambda(\text{coker } d^2_w, \ker d_2)$. This completes the proof of Lemma 6.8. \hfill \Box

7. Proof of Theorem A

Let $\text{hCW}_*$ denote the category whose objects are based connected CW-complexes and whose morphisms are based homotopy classes of maps. Let $\text{hCW}_2$ be the full subcategory of based, connected, and 3-connected (i.e. homotopy groups vanish for $i \geq 3$) CW-complexes. Taking the second stage of the Postnikov tower gives a functor $P_2: \text{hCW}_* \to \text{hCW}_2$. As discussed in the introduction, the $k$-invariant $k(X) \in H^3(\pi_4(X); \pi_3(X))$ of $X \in \text{CW}_*$ classifies the fibration

$$
K(\pi_3(X), 2) \longrightarrow P_2(X) \longrightarrow K(\pi_1(X), 1).
$$

Let $\text{hCW}_2(\pi)$ be the full subcategory of $\text{hCW}_2$ of objects with fundamental group $\pi$. For each $X \in \text{hCW}_2(\pi)$, define $\mathfrak{I}(X) \in \text{sCh}_2(\pi)$ as follows: take a $\Lambda$-module chain complex $(C_*, d_*)$ for $X$ and replace it in degrees $\geq 4$ by a free resolution of $\ker d_3$.

**Proposition 7.1.** Let $M$ be a closed 4-manifold with 1-type $(\pi, w)$ and chain complex $(C_* = C_*(M; \Lambda), d_*)$. The composition

$$
H_4(\pi; \mathbb{Z}^w) \longrightarrow \text{Ext}^1_\Lambda(\text{coker } d_3, \ker d_2)/\text{sAut}(\text{coker } d_3) \stackrel{\Theta}{\longrightarrow} \text{sCh}_2(\pi)
$$

sends the (twisted) fundamental class $c_*[M]$ to $\mathfrak{I}(P_2(M))$.

**Proof.** Fix a 4-manifold $M$ with $\pi_1(M) = \pi$ and choose a handle decomposition of $M$. Denote the associated $\Lambda$-chain complex by $(C_*, d_*)$. We apply the theory from Section 6 with $\cdots \to B_4 \to B_3 \xrightarrow{b} B_2$ as $\cdots \to B_4 \to C_3 \xrightarrow{d_3} C_2$, a free resolution for $\text{coker}(d_3)$ beginning with $d_3: C_3 \to C_2$. Any two choices of handle decomposition induce chain equivalent chain complexes $C_*$, and stably equivalent modules $\text{coker } d_3$. It follows from Lemma 6.5 and Lemma 6.7 that the image of
Consider \( \Theta \) applied to the extension class of \( \pi_2(M) \) in \( \text{Ext}^1_A(\text{coker} \, d_3, \text{ker} \, d_2) \). This extension class is represented by the homomorphism \( d_3 : C_3 \to C_2 \), we consider the chain complex \( C_{d_3} \):

\[
\cdots \to C_3(d_3, d_3)^T \xrightarrow{d_2} C_2 \oplus C_2 \xrightarrow{(d_2, 0)} C_1 \xrightarrow{d_1} C_0.
\]

Use the isomorphism \((\begin{smallmatrix}1 & 0 \\ \text{id} & \text{id} \end{smallmatrix}) : C_2 \oplus C_2 \to C_2 \oplus C_2\) to see that the previously displayed chain complex is chain isomorphic to the chain complex \( \mathbb{Z}(P_2(M)) \oplus \Lambda^{\text{rank}(C_2)}[2] \) (replace the second \( d_3 \) in \( (d_3, d_3) \) with \( 0 \)). Hence in \( \text{sCh}_2(\pi) \), \( \Theta([d_3]) \) agrees with \( \mathbb{Z}(P_2(M)) \) as desired. \( \square \)

Note that each stable automorphism of \( \text{coker} \, b_3 \) induces an automorphism of the extension group and hence the trivial element is fixed by the action. Therefore, combining Theorem 6.6 and Proposition 7.1 with Theorem 1.11 yields the following corollary.

**Corollary 7.2.** The \( \mathbb{CP}^2 \)-stable diffeomorphism class represented by the trivial extension is detected by the stable 2-type \((\pi, w, \pi_2, k)\). More precisely, let \( K \) be a 2-complex representing \((\pi, w)\). For every 1-type \((\pi, w)\), a closed 4-manifold \( M \) with this 1-type is \( \mathbb{CP}^2 \)-stably diffeomorphic to the double \( N := \nu K \cup -\nu K \) if and only if the 2-types \([\pi_2(M), k(M)] = [\pi_2(N), k(N)]\) are stably isomorphic.

**Proof of Theorem A.** By [Geo08, Proposition 13.5.3 and Theorem 13.5.5], a group \( \pi \) with one end is infinite and has \( H^1(\pi; \Lambda) = 0 \). Hence Theorem A (ii) follows by combining Theorem 1.11 with Theorem 6.6, Proposition 7.1 and Lemma 6.8. In more detail, recall that Theorem 1.11 says that the extension class of \( \pi_2(M) \) in \( \text{Ext}(H^2(K; \Lambda^w), H_2(K; \Lambda)) \cong H_4(\pi; \mathbb{Z}^w) \) determines \( c_4[M] \) up to sign, which by Theorem 1.2 determines \( \mathbb{CP}^2 \)-stable diffeomorphism. By Theorem 6.6 and Proposition 7.1 the pair \((\pi_2(M), k(M))\) determines the extension class, up to the action of \( \text{sAut}(\text{coker} \, d_3^w) \). By Lemma 6.8, the action of \( \text{sAut}(\text{coker} \, d_3^w) \) is just multiplication by \( \pm 1 \), so altogether \((\pi_2(M), k(M))\) determines \( c_4[M] \) up to sign.

If \( \pi \) is torsion-free, then by Stalling’s theorem [Sta68, Theorems 4.11 and 5.1], \( \pi \) has more than one end if and only if \( \pi \cong \mathbb{Z} \) or \( \pi \) is a free product of two non-trivial groups. For \( \pi = \mathbb{Z} \), \( H_4(\pi; \mathbb{Z}^w) = 0 \), hence every pair of closed 4-manifolds is with a fixed 1-type is \( \mathbb{CP}^2 \)-stably diffeomorphic. Hence the conclusion of Theorem A holds for \( \pi = \mathbb{Z} \) for trivial reasons.

For \( \pi \cong G_1 \ast G_2 \), we have \( H_4(\pi; \mathbb{Z}^w) \cong H_4(G_1; \mathbb{Z}^{w_1}) \oplus H_4(G_2; \mathbb{Z}^{w_2}) \), where \( w_i \) denotes the restriction of \( w \) to \( G_i \), \( i = 1, 2 \). Hence \( \mathbb{CP}^2 \)-stably any closed 4-manifold with fundamental group \( \pi \) is the connected sum of manifolds with fundamental group \( G_1 \) and \( G_2 \). Therefore, Theorem A (i) follows in this case by induction, with base cases \( \pi = \mathbb{Z} \) or the groups with one end of (ii).

If \( \pi \) is finite then \( H^1(\pi; \Lambda) = 0 \) by [Geo08, Proposition 13.3.1]. If multiplication by 4 or 6 annihilates \( H_4(\pi; \mathbb{Z}^w) \), then the subgroup generated by \( c_4[M] \) is cyclic of order 2, 3, 4 or 6. In each case it has a unique generator up to sign and hence it determines \( c_4[M] \) up to a sign. As a consequence, Theorem A (iii) follows from Corollary 4.3, which shows that the subgroup generated by \( c_4[M] \) is determined by the 2-type of \( M \). \( \square \)
8. Fundamental groups of aspherical 4-manifolds

In this section, we fix a closed, connected, aspherical 4-manifold $X$ with orientation character $w$ and fundamental group $\pi$. We can identify

$$H_4(\pi; \mathbb{Z}^w)/\pm \operatorname{Aut}(\pi) \cong H_4(X; \mathbb{Z}^w)/\pm \operatorname{Aut}(\pi) \cong \mathbb{Z}/\pm \cong \mathbb{N}_0$$

and write $|c_4[M]|$ for the image of $c_4[M]$ under this sequence of maps.

**Theorem 8.1.** Let $M$ be a closed 4-manifold with 1-type $(\pi, w)$ and classifying map $c: M \to X = B\pi$.

1. If $|c_4[M]| \neq 0$, then $H_1(\pi; \pi_2(M)^w)$ is a cyclic group of order $|c_4[M]|$.

2. If $|c_4[M]| = 0$, then $H_1(\pi; \pi_2(M)^w)$ is an isomorphism. Thus two closed 4-manifolds $M_1$ and $M_2$ with fundamental group $\pi$ and orientation character $w$ are $\mathbb{CP}^2$-stably diffeomorphic if and only if they have stably isomorphic second homotopy groups $\pi_2(M_1) \oplus \Lambda^{r_1} \cong \pi_2(M_2) \oplus \Lambda^{r_2}$ for some $r_1, r_2 \in \mathbb{N}_0$.

**Proof.** For the proof, we fix twisted orientations on $M$ and $X$. In particular this determines an identification $H_4(X; \mathbb{Z}^w) = \mathbb{Z}$.

Since $c: M \to X$ induces an isomorphism on fundamental groups, the map $c^*: H^1(X; \mathbb{Z}) \to H^1(M; \mathbb{Z})$ is an isomorphism. Consider the following commutative square.

$$\begin{array}{ccc}
H_3(M; \mathbb{Z}^w) & \xrightarrow{c_*} & H_3(X; \mathbb{Z}^w) \\
-\cap[M] & \cong & -\cap c_4[M] \\
H^1(M; \mathbb{Z}) & \xrightarrow{c^*} & H^1(X; \mathbb{Z})
\end{array}$$

Since $H^1(X; \mathbb{Z})$ is torsion free and capping with $[X]$ is an isomorphism, capping with $c_4[M]$ is injective if $c_4[M] \neq 0$. Thus from Theorem 4.1 we directly obtain the isomorphism $\mathbb{Z}/|c_4[M]| \cong H_1(\pi; \pi_2(M)^w)$.

If $c_4[M] = 0$, then it also follows from Theorem 4.1 that $\mathbb{Z} \cong H_4(\pi; \mathbb{Z}^w)$ is a subgroup of $H_4(\pi; \pi_2(M)^w)$, and hence the latter is infinite. \qed

We can also show that under certain assumptions, $|c_4[M]|$ can be extracted from the stable isomorphism class of $\mathbb{Z}^w \otimes_\Lambda \pi_2(M)$, an abelian group that is frequently much easier to compute than the $\Lambda$-module $\pi_2(M)$.

**Theorem 8.2.** In the notation of Theorem 8.1, assume that $H^1(X; \mathbb{Z}) \neq 0$. Then

1. If $c_4[M] \neq 0$, then $|c_4[M]|$ is the highest torsion in $\mathbb{Z}^w \otimes_\Lambda \pi_2(M)$, that is the maximal order of torsion elements in this abelian group.

2. If $H^2(X; \mathbb{Z})$ has torsion, then $|c_4[M]|$ is completely determined by the torsion subgroup of $\mathbb{Z}^w \otimes_\Lambda \pi_2(M)$. This torsion subgroup is trivial if and only if $|c_4[M]| = 1$.

3. If $H^2(X; \mathbb{Z})$ is torsion-free, then $|c_4[M]| = 1$ if and only if $\pi_2(M)$ is projective, and otherwise $|c_4[M]|$ is completely determined by the torsion subgroup of $\mathbb{Z}^w \otimes_\Lambda \pi_2(M)$. This torsion subgroup is trivial if and only if $|c_4[M]| \in \{0, 1\}$.

Except for the statement that $c_4[M]$ corresponds to the highest torsion in $\mathbb{Z}^w \otimes_\Lambda \pi_2(M)$, the above theorem can be proven more easily using the exact sequence from Theorem 4.1. But since we believe that this statement is worth knowing, we take a different approach and start with some lemmas. For the lemmas we do not yet need
the assumption that $H^1(\pi; \mathbb{Z}) = H^1(X; \mathbb{Z}) \neq 0$; we will point out in the proof of Theorem 8.2 where this hypothesis appears. Choose a handle decomposition of $X$ with a single 4-handle and a single 0-handle and let $(C_*, d_4)$ denote the $\Lambda$-module chain complex of $X$ associated to this handle decomposition.

**Lemma 8.3.** The group $\text{Ext}^1_A(\text{coker} \, d_3, \text{ker} \, d_2) \cong H_4(\pi; \mathbb{Z}^w) \cong \mathbb{Z}$ is generated by

$$0 \to \text{ker} \, d_2 \overset{i}{\to} C_2 \overset{p}{\to} \text{coker} \, d_3 \to 0.$$  

**Proof.** By Proposition 1.10 the extension $0 \to \text{ker} \, d_2 \overset{i}{\to} C_2 \overset{p}{\to} \text{coker} \, d_3 \to 0$ corresponds to $c_*[X] \in H_4(\pi; \mathbb{Z}^w)$, where $c : X \to B\pi$ is the map classifying the fundamental group. Since in this case $X$ is a model for $B\pi$, we can take $c = \text{Id}_X$ with $[X]$ a generator of $H_4(X; \mathbb{Z}^w)$. □

**Lemma 8.4.** Using the generator from Lemma 8.3, the extension corresponding to $m \in \mathbb{Z}$ is given by

$$0 \to \text{ker} \, d_2 \xrightarrow{(0,1)d^T} (C_2 \oplus \text{ker} \, d_2)/\{(i(a), ma) \mid a \in \text{ker} \, d_2\} \xrightarrow{p \circ p_1} \text{coker} \, d_3 \to 0,$$

where $p_1$ is the projection onto the first summand.

Note that $m = 0$ gives the direct sum $E_0 = \text{ker} \, d_2 \oplus \text{coker} \, d_3$.

**Proof.** In the case $m = 1$, the group $(C_2 \oplus \text{ker} \, d_2)/\{(i(a), a) \mid a \in \text{ker} \, d_2\}$ is isomorphic to $(C_2 \oplus \text{ker} \, d_2)/\{(0, a) \mid a \in \text{ker} \, d_2\} \cong C_2$, where this isomorphism is induced by the isomorphism $C_2 \oplus \text{ker} \, d_2 \to C_2 \oplus \text{ker} \, d_2$ given by $(c, a) \mapsto (c - i(a), a)$. Under this isomorphism the extension from the lemma is mapped to the extension from Lemma 8.3. Hence it suffices to show that the Baer sum of two extension for $m, m'$ as in the lemma is isomorphic to the given extension for $m + m'$.

Let $L$ be the submodule of $C_2 \oplus \text{ker} \, d_2 \oplus C_2 \oplus \text{ker} \, d_2$ consisting of all $(c_1, a_1, c_2, a_2)$ with $p(c_1) = p(c_2)$, let $L' := L/L'$. The Baer sum [Wei94, Definition 3.4.4.] of the extensions for $m$ and $m'$ is given by

$$0 \to \text{ker} \, d_2 \to E \to \text{coker} \, d_3 \to 0,$$

where the map $\text{ker} \, d_2 \to E$ is given by $a \mapsto [0, a, 0, 0]$ and the map $E \to \text{coker} \, d_3$ is given by $[(c_1, a_1, c_2, a_2)] \mapsto p(c_1)$. The map

$$f : L \to C_2 \oplus \text{ker} \, d_2 \oplus \text{ker} \, d_2 \oplus \text{ker} \, d_2 \quad (c_1, a_1, c_2, a_2) \mapsto (c_1, a_1 + a_2 + m'(c_1 - c_2), c_2 - c_1, a_2)$$

defines an isomorphism, and the subset $L'$ is mapped to

$$f(L') = \{(i(a), (m + m')a, a' - a, m'a' - b) \mid a, a', b \in \text{ker} \, d_2\}$$

$$= \{(i(a), (m + m')a, a', b) \mid a, a', b \in \text{ker} \, d_2\}.$$  

Hence $f$ induces an isomorphism

$$E \cong (C_2 \oplus (\text{ker} \, d_2)^3)/f(L') \cong (C_2 \oplus \text{ker} \, d_2)/\{(i(a), (m + m')a) \mid a \in \text{ker} \, d_2\}.$$

This defines an isomorphism from the Baer sum to the extension for $m + m'$ from the statement of the lemma. □
Lemma 8.5. Let $0 \rightarrow \ker d_2 \rightarrow E_m \rightarrow \coker d_3 \rightarrow 0$ be the extension for $m \in \mathbb{Z}$ from Lemma 8.4. Then

$$\mathbb{Z}^w \otimes_{\Lambda} E_m \cong \{(\mathbb{Z}^w \otimes_{\Lambda} C_2) \oplus (\mathbb{Z}^w \otimes_{\Lambda} C_3) \mid \text{a } a \in \mathbb{Z}^w \otimes_{\Lambda} C_3\}.$$  

Proof. Note that $\text{Id}_{\mathbb{Z}^w} \otimes d_4 = 0$, since $X$ has orientation character $w$ and thus $H_4(X; \mathbb{Z}^w) \cong \mathbb{Z}^w \otimes_{\Lambda} C_4 \cong \mathbb{Z}$. By exactness, $\ker d_2 = \text{im} d_3 \cong \text{coker} d_4$. By right exactness of the tensor product, it follows that $\mathbb{Z}^w \otimes_{\Lambda} \ker d_2 \cong \text{coker}(\text{Id}_{\mathbb{Z}^w} \otimes d_4) \cong \mathbb{Z}^w \otimes_{\Lambda} C_3$. Tensor the diagram

$$\begin{array}{ccc}
C_3 & \xrightarrow{d_3} & C_2 \\
\downarrow \text{ker} d_2 & & \\
\end{array}$$

with $\mathbb{Z}^w$ over $\Lambda$, to obtain

$$\begin{array}{ccc}
\mathbb{Z}^w \otimes_{\Lambda} C_3 & \xrightarrow{\text{Id}_{\mathbb{Z}^w} \otimes d_3} & \mathbb{Z}^w \otimes_{\Lambda} C_2 \\
\downarrow \cong & & \downarrow \text{Id}_{\mathbb{Z}^w} \otimes 1 \\
\mathbb{Z}^w \otimes_{\Lambda} \ker d_2
\end{array}$$

The lemma now follows from right exactness of the tensor product. \hfill \Box

Proof of Theorem 8.2. Let $E_m$ be as in Lemma 8.5. By Proposition 1.9 and Proposition 1.10, $\pi_2(M)$ is stably isomorphic to $E_m$ as a $\Lambda$-module if $c_4[M] = \pm m$. All of the conditions appearing in Theorem 8.2 are invariant under adding a free $\Lambda$-summand to $\pi_2(M)$. Since for any extension and its negative, the middle groups are isomorphic, we have $E_m \cong E_{-m}$. Hence we can only obtain a distinction up to sign.

The boundary map $\text{Id}_{\mathbb{Z}^w} \otimes d_4 : \mathbb{Z}^w \otimes_{\Lambda} C_3 \rightarrow \mathbb{Z}^w \otimes_{\Lambda} C_3$ vanishes since $H_4(X; \mathbb{Z}^w) \cong \mathbb{Z}$ and $X$ has a unique 4-handle. Hence $H_3(X; \mathbb{Z}^w) \cong \ker(\text{Id}_{\mathbb{Z}^w} \otimes d_3)$. By Poincaré duality

$$H^1(\pi; \mathbb{Z}) \cong H^1(X; \mathbb{Z}) \cong H_3(X; \mathbb{Z}^w) \cong \ker(\text{Id}_{\mathbb{Z}^w} \otimes d_3).$$

Claim. The cokernel of $\text{Id}_{\mathbb{Z}^w} \otimes d_3 : \mathbb{Z}^w \otimes_{\Lambda} C_3 \rightarrow \mathbb{Z}^w \otimes_{\Lambda} C_2$ is stably isomorphic to $H_2(\pi; \mathbb{Z}^w) \cong H^2(\pi; \mathbb{Z})$.

We have a cochain complex:

$$\begin{array}{ccc}
\mathbb{Z}^w \otimes_{\Lambda} C_3 & \xrightarrow{\text{Id}_{\mathbb{Z}^w} \otimes d_3} & \mathbb{Z}^w \otimes_{\Lambda} C_2 \\
\downarrow \text{Id}_{\mathbb{Z}^w} \otimes d_2 & & \downarrow \text{Id}_{\mathbb{Z}^w} \otimes d_2 \\
\mathbb{Z}^w \otimes_{\Lambda} C_1
\end{array}$$

whose cohomology $\ker(\text{Id}_{\mathbb{Z}^w} \otimes d_2)/\text{im}(\text{Id}_{\mathbb{Z}^w} \otimes d_3)$ is isomorphic to $H_2(\pi; \mathbb{Z}^w)$. There is an exact sequence:

$$0 \rightarrow \ker(\text{Id}_{\mathbb{Z}^w} \otimes d_2)/\text{im}(\text{Id}_{\mathbb{Z}^w} \otimes d_3) \rightarrow \mathbb{Z}^w \otimes_{\Lambda} C_2 \rightarrow \mathbb{Z}^w \otimes_{\Lambda} C_2 \rightarrow 0.$$ 

Since $\mathbb{Z}^w \otimes_{\Lambda} C_2/\ker(\text{Id}_{\mathbb{Z}^w} \otimes d_2) \cong \text{im}(\text{Id}_{\mathbb{Z}^w} \otimes d_3)$, and $\text{im}(\text{Id}_{\mathbb{Z}^w} \otimes d_3)$ as a submodule of the free abelian group $\mathbb{Z}^w \otimes_{\Lambda} C_1$ is free, we see that there is a stable isomorphism of the central group

$$H_2(\pi; \mathbb{Z}^w) = \ker(\text{Id}_{\mathbb{Z}^w} \otimes d_3 : \mathbb{Z}^w \otimes_{\Lambda} C_3 \rightarrow \mathbb{Z}^w \otimes_{\Lambda} C_2)$$

with $H_2(\pi; \mathbb{Z}^w)$, as claimed.
By applying elementary row and column operations, \( \text{Id}_{\mathbb{Z}^w} \otimes d_3 : \mathbb{Z}^w \otimes_{\Lambda} C_3 \to \mathbb{Z}^w \otimes_{\Lambda} C_2 \) can be written as
\[
\mathbb{Z}^a \oplus \mathbb{Z}^k \xrightarrow{\begin{pmatrix} 0 & 0 \\ 0 & D \end{pmatrix}} \mathbb{Z}^b \oplus \mathbb{Z}^k,
\]
with \( a \geq 1, b \geq 0 \) and \( D \) a diagonal matrix with entries \( \delta_1, \ldots, \delta_k \in \mathbb{N} \setminus \{0\} \).

In order to see that \( a \geq 1 \), we use that the kernel is \( H^1(\pi; \mathbb{Z}) \) together with the hypothesis that \( H^1(X; \mathbb{Z}) \cong H^1(\pi; \mathbb{Z}) \neq 0 \).

Using the description from Lemma 8.5, stably
\[
\mathbb{Z}^w \otimes_{\Lambda} E_m \cong_s (\mathbb{Z}/m\mathbb{Z})^a \oplus \bigoplus_{i=1}^k \mathbb{Z}/\gcd(\delta_i, m)\mathbb{Z}.
\]
If \( m \neq 0 \), then the highest torsion in \( \mathbb{Z}^w \otimes_{\Lambda} E_m \) is \( m \)-torsion. Thus \( E_m \) is not isomorphic to \( E_{m'} \) whenever \( m \neq m' \) and both are nonzero. It remains to distinguish \( E_0 \) from \( E_m \) for \( m \neq 0 \) (recall \( \gcd(\delta_i, 0) = \delta_i \)).

First let us assume that the torsion subgroup \( TH^2(\pi; \mathbb{Z}) \) is nontrivial. Then the cokernel of \((8.6)\) is not free, and hence there exists \( 1 \leq j \leq k \) with \( \delta_j > 1 \). Thus \( \mathbb{Z}^w \otimes_{\Lambda} E_0 \cong \bigoplus_{i=1}^k \mathbb{Z}/\delta_i \mathbb{Z} \) is not torsion free. Since \( \mathbb{Z}^w \otimes_{\Lambda} E_m \) can only contain \( \delta_i \)-torsion if \( \delta_i \) divides \( m \), \( \mathbb{Z}^w \otimes_{\Lambda} E_0 \) and \( \mathbb{Z}^w \otimes_{\Lambda} E_m \) can only be stably isomorphic if all the \( \delta_i \) divide \( m \). This already implies \( |m| > 1 \). But in this case
\[
\mathbb{Z}^w \otimes_{\Lambda} E_m \cong (\mathbb{Z}/m\mathbb{Z})^a \oplus \bigoplus_{i=1}^k \mathbb{Z}/\delta_i \mathbb{Z} \cong (\mathbb{Z}/m\mathbb{Z})^a \oplus \mathbb{Z}^w \otimes_{\Lambda} E_0,
\]
and so \( \mathbb{Z}^w \otimes_{\Lambda} E_0 \) and \( \mathbb{Z}^w \otimes_{\Lambda} E_m \) are not stably isomorphic, since \( a \geq 1 \). This completes the proof of case where \( TH^2(\pi; \mathbb{Z}) \) is nontrivial.

If \( H^2(\pi; \mathbb{Z}) \) is torsion free, then all the \( \delta_i \) are 1 and \( \mathbb{Z}^w \otimes_{\Lambda} E_m \cong_s (\mathbb{Z}/m\mathbb{Z})^a \).
This already distinguishes the cases \( |m| > 1 \) and \( m \in \{0, \pm 1\} \). For \( m = \pm 1 \), we have \( E_m \cong C_2 \) is free and for \( m = 0 \) we have \( E_0 = \ker d_2 \oplus \ker d_3 \). Note that \( \ker d_2 \) is not projective, since otherwise
\[
0 \to \ker d_2 \to C_2 \to C_1 \to C_0
\]
would be a projective \( \Lambda \)-module resolution for \( \mathbb{Z} \), which cannot be chain equivalent to the \( \Lambda \)-module chain complex of a closed aspherical 4-manifold with fundamental group \( \pi \). Therefore, \( E_0 \) is not projective.

\[ \blacksquare \]

**Remark 8.7.** Note that the assumption that \( H^1(X; \mathbb{Z}) \cong H^1(\pi; \mathbb{Z}) \neq 0 \) is equivalent to the abelianisation \( \pi_{ab} \) being infinite, since \( H^1(\pi; \mathbb{Z}) = \text{Hom}(\pi_{ab}, \mathbb{Z}) \) and \( \pi_{ab} \) is finitely generated. This assumption is crucial; without it there exist \( m > m' \geq 0 \) with \( \mathbb{Z}^w \otimes_{\Lambda} E_m \cong \mathbb{Z}^w \otimes_{\Lambda} E_{m'} \). For example this would happen for \( m = \prod_{i=1}^k \delta_i \) and \( m' = 2m \), where the \( \delta_i \) are as in the proof of Theorem 8.2.

9. **Examples demonstrating necessity of hypotheses**

In the preceding sections we saw that for large classes of finitely presented groups, such as infinite groups \( \pi \) with \( H^1(\pi; \Lambda) = 0 \), the quadruple \( (\pi_1, w, \pi_2, k) \) detects the \( \mathbb{CP}^2 \)-stable diffeomorphism type. Moreover for fundamental groups of aspherical 4-manifolds even \( (\pi_1, w, \pi_2) \) suffices. In this section we give examples where the data \( (\pi_1, w, \pi_2, k) \) does not suffice to detect the \( \mathbb{CP}^2 \)-stable diffeomorphism classification, showing that the hypothesis \( H^1(\pi; \Lambda) = 0 \) is required. We also provide
examples where the data is sufficient to detect the classification, but the $k$-invariant is relevant, so all of the data is necessary.

9.1. The 2-type does not suffice in general. In this section, as promised in Section 1.2, we give examples of orientable manifolds that are not $\mathbb{C}P^2$-stably diffeomorphic, but with isomorphic 2-types.

It will be helpful to recall the construction of 3-dimensional lens spaces $L_{p,q}$. Start with the unit sphere in $\mathbb{S}^3$ and let $\xi$ be a $p$th root of unity. On the unit sphere, $\mathbb{Z}/p$ acts freely by $(z_1,z_2) \mapsto (\xi z_1, \xi^q z_2)$ for $0 < q < p$ such that $p,q$ are coprime. The quotient of $S^3 \subset \mathbb{C}^2$ by this action is $L_{p,q}$.

Now fix an integer $p \geq 2$, let $\pi := \mathbb{Z}/p \times \mathbb{Z}$ and consider the 4-manifolds $N_{p,q} := L_{p,q} \times S^1$. Note that $\pi_2(N_{p,q}) = \pi_2(\tilde{N}_{p,q}) = \pi_2(S^3 \times \mathbb{R}) = 0$. Thus the stable Postnikov 2-type is trivial for all $p,q$, and the number $q$ cannot possibly be read off from the 2-type.

Nevertheless, we will show below that for most choices of $p$, there are $q, q'$ for which the resulting manifolds $N_{p,q}$ and $N_{p,q'}$ are not $\mathbb{C}P^2$-stably diffeomorphic. The smallest pair is $N_{5,1}$ and $N_{5,2}$, corresponding to the simplest homotopically inequivalent lens spaces $L_{5,1}$ and $L_{5,2}$ with isomorphic fundamental groups. In general, compute using the equivalence of (i) and (iv) of Proposition 9.2 below.

Although $\pi$ is infinite, by the following lemma the group $\pi$ has two ends, so these examples are consistent with our earlier investigations.

Lemma 9.1. We have that $H^1(\pi; \Lambda) \cong \mathbb{Z}$.

Proof. We compute using the fact that the manifold can be made into a model for $B\pi$ by adding cells of dimension 3 and higher, which do not alter the first cohomology.

$$H^1(\pi; \Lambda) \cong H^1(N_{p,q}; \Lambda)^{PD} \cong H_3(N_{p,q}; \Lambda) \cong H_3(\tilde{N}_{p,q}; \mathbb{Z}) \cong H_3(S^3 \times \mathbb{R}; \mathbb{Z}) \cong \mathbb{Z}. \square$$

Proposition 9.2. The following are equivalent:

(i) $N_{p,q}$ and $N_{p,q'}$ are $\mathbb{C}P^2$-stably diffeomorphic;
(ii) $c_*(N_{p,q}) = c_*(N_{p,q'}) \in H_3(\mathbb{Z}/p \times \mathbb{Z})/\pm \text{Aut}(\mathbb{Z}/p \times \mathbb{Z})$;
(iii) $c_*(L_{p,q}) = c_*(L_{p,q'}) \in H_3(\mathbb{Z}/p)/\pm \text{Aut}(\mathbb{Z}/p)$;
(iv) $q \equiv \pm r^2 q' \mod p$ for some $r \in \mathbb{Z}$;
(v) $L_{p,q}$ and $L_{p,q'}$ are homotopy equivalent;
(vi) The $\mathbb{Q}/\mathbb{Z}$-valued linking forms of $L_{p,q}$ and $L_{p,q'}$ are isometric.

Proof. Items (i) and (ii) are equivalent by Theorem 1.2. By the Künneth theorem,

$$H_3(\mathbb{Z}/p \times \mathbb{Z}) \cong H_3(\mathbb{Z}/p) \otimes_{\mathbb{Z}} H_1(\mathbb{Z}) \cong H_3(\mathbb{Z}/p) \cong \mathbb{Z}/p.$$

The image of $c_*(L_{p,q}) \in H_3(\mathbb{Z}/p)$ under this identification is precisely $c_*(N_{p,q})$, since $B\mathbb{Z} = S^3$. Thus (iii) and (ii) are equivalent by the construction of $N_{p,q}$.

Let $m$ be such that $mq = 1 \mod p$. Then there is a degree $m$ map $g: L_{p,q} \to L_{p,1}$ that induces an isomorphism on fundamental groups, given by $[z_1, z_2] \mapsto [z_1, z_2^m]$. Take $c_*(L_{p,1})$ as the generator of $H_3(\mathbb{Z}/p)$. Then $c_* \circ g_*[L_{p,q}] = mc_*[L_{p,1}]$ corresponds to the element $m = q^{-1} \in \mathbb{Z}/p \cong H_3(\mathbb{Z}/p)$. An element $r \in (\mathbb{Z}/p)^\times \cong \text{Aut}(\mathbb{Z}/p)$ acts on $H_1(\mathbb{Z}/p) \cong \mathbb{Z}/p$ and hence also on $H^2(\mathbb{Z}/p) \cong \text{Ext}_{\mathbb{Z}}^1(\mathbb{Z})(H_1(\mathbb{Z}/p), \mathbb{Z}) \cong \mathbb{Z}/p$ by taking the product with $r$. Since $H^4(\mathbb{Z}/p) \cong \mathbb{Z}[x]/(px)$, where the generator $x$ lies in degree two [Hat02, Example 3.41], $r$ acts on $H^4(\mathbb{Z}/p) \cong \text{Ext}_{\mathbb{Z}}^1(\mathbb{Z})(H_3(\mathbb{Z}/p), \mathbb{Z})$
via multiplication by \( r^2 \). Therefore, the action of \( r \) on \( H_3(\mathbb{Z}/p) \cong \mathbb{Z}/p \) is also multiplication by \( r^2 \). Hence (iii) and (iv) are equivalent.

Items (iv) and (v) are equivalent by [Whi41, Theorem 10]. Seifert [Sei33] computed that the linking form \( H_1(L_{p,q}) \times H_1(L_{p,q}) \to \mathbb{Q}/\mathbb{Z} \) is isometric to

\[
\mathbb{Z}/p \times \mathbb{Z}/p \to \mathbb{Q}/\mathbb{Z},
\]

\[(x, y) \mapsto -qx y/p.\]

For \( q \) and \( q' \), the associated forms are isometric up to a sign if and only if (iv) is satisfied. Thus (iv) and (vi) are equivalent.

\[\Box\]

### 9.2. The \( k \)-invariant is required in general

In this section we give examples where the \( \mathbb{C}P^2 \)-stable classification is determined by the 2-type, but in contrast to the case that \( \pi \) is the fundamental group of some aspherical 4-manifold, here the stable isomorphism class of the second homotopy group is not sufficient to determine the classification. As with the examples in the previous section, these examples can be compared with [Tei92, Conjecture A], although we remark that this conjecture was only made for finite groups.

Let \( X \) be a closed, oriented, aspherical 3-manifold with fundamental group \( G \). Let \( p \geq 2 \), let \( 1 \leq q < p \), and let \( X_{p,q} := L_{p,q} \# X \) and \( M_{p,q} := X_{p,q} \times S^1 \). Then \( M_{p,q} \) is a closed 4-manifold with fundamental group \( \pi := (\mathbb{Z}/p \ast G) \times \mathbb{Z} \).

**Lemma 9.3.** The group \( \pi \) is infinite and has \( H^1(\pi; \Lambda) = 0 \). In particular, the pair \((\pi_2, k)\) suffices for the \( \mathbb{C}P^2 \)-stable classification over \( \pi \) of oriented manifolds.

**Proof.** Certainly \( \pi = (\mathbb{Z}/p \ast G) \times \mathbb{Z} \) is infinite. Since \( \pi_1(X) = G \) is nontrivial, \( \pi_1(X_{p,q}) = \mathbb{Z}/p \ast G \) is infinite, and hence \( \tilde{X}_{p,q} \) is a noncompact 3-manifold, so \( H_3(\tilde{X}_{p,q}; \mathbb{Z}) = 0 \). Since \( \pi_1(M_{p,q}) = \pi \), we see that

\[
H^1(\pi, \Lambda) = H^1(M_{p,q}; \Lambda) \cong H_3(M_{p,q}; \Lambda) \cong H_3(\tilde{X}_{p,q} \times \mathbb{R}; \mathbb{Z}) \cong H_3(\tilde{X}_{p,q}; \mathbb{Z}) = 0.
\]

The second sentence of the lemma then follows from Theorem A (ii).

\[\Box\]

**Lemma 9.4.** The second homotopy group \( \pi_2(X_{p,q}) \) is independent of \( q \).

**Proof.** We show the following statement, from which the lemma follows by taking \( Y_1 = L_{p,q} \) and \( Y_2 = X \): let \( Y_1, Y_2 \) be closed, connected, oriented 3-manifolds with \( \pi_2(Y_1) = \pi_2(Y_2) = 0 \). Suppose that \( G_1 := \pi_1(Y_1) \) is finite and \( G_2 := \pi_1(Y_2) \) is infinite. Then \( \pi_2(Y_1 \# Y_2) \) depends only on \( G_1 \) and \( G_2 \).

To investigate \( \pi_2(Y_1 \# Y_2) = \pi_2(Y_1 \# Y_2; \mathbb{Z}[G_1 \ast G_2]) \), we start by computing \( H_2(\text{cl}(Y_1 \setminus D^3); \mathbb{Z}[G_1 \ast G_2]) \). For the rest of the proof we write

\[
R := \mathbb{Z}[G_1 \ast G_2].
\]

Consider the Mayer-Vietoris sequence for the decomposition \( Y_1 = \text{cl}(Y_1 \setminus D^3) \cup S^2 D^3 \):

\[
0 \to H_3(Y_i; R) \to H_2(S^2; R) \to H_2(\text{cl}(Y_i \setminus D^3); R) \oplus H_2(D^3; R) \to H_2(Y_i; R).
\]

We have \( H_2(Y_i; R) \cong R \otimes \mathbb{Z}[G_i] \), \( \pi_2(Y_i) = 0 \), \( H_2(S^2; R) \cong R \otimes \mathbb{Z}[G_1] \otimes \mathbb{Z}[G_1] \) and

\[
H_3(Y_i; R) = \begin{cases} R \otimes \mathbb{Z}[G_i] & |G_i| < \infty \\ 0 & |G_i| = \infty. \end{cases}
\]

In the case that \( G_i \) is finite, the boundary map is given by

\[
\text{Id} \otimes N: R \otimes \mathbb{Z}[G_i] \to R \otimes \mathbb{Z}[G_i],
\]
where $N: 1 \mapsto \sum_{g \in G} g$ sends the generator of $\mathbb{Z}$ to the norm element of $\mathbb{Z}[G_i]$. Thus

$$H_2(\text{cl}(Y_1 \setminus D^3); R) = \begin{cases} \text{coker}(\text{Id} \otimes N) & |G_i| < \infty \\ R & |G_i| = \infty. \end{cases}$$

Now, as in the hypothesis of the statement we are proving, take $G_1$ to be finite and $G_2$ infinite. Then the Mayer-Vietoris sequence for $Y_1 \# Y_2$,

$$0 \to H_3(Y_1 \# Y_2; R) \to H_2(\text{cl}(Y_1 \setminus D^3); R) \oplus H_2(\text{cl}(Y_2 \setminus D^3); R) \to H_2(Y_1 \# Y_2; R) \to 0$$

becomes

$$0 \to R \xrightarrow{\text{coker}(\text{Id} \otimes N) \oplus R} H_2(Y_1 \# Y_2; R) \to 0.$$ 

From the first Mayer-Vietoris sequence above, in the case that $G_i$ is infinite, we see that the map $R \xrightarrow{\text{coker}(\text{Id} \otimes N) \oplus R}$ $\xrightarrow{\text{pr}_2}$ $R$ is an isomorphism, where $\text{pr}_2$ is the projection to the $R$ summand. It follows that

$$\pi_2(Y_1 \# Y_2) \cong H_2(Y_1 \# Y_2; R) \cong \text{coker} \left( \text{Id} \otimes N: R \otimes \mathbb{Z}[G_i] \mathbb{Z} \to R \otimes \mathbb{Z}[G_i] \mathbb{Z}[G_i] \right).$$

This $R$-module depends only on the groups $G_1$ and $G_2$, as desired. \hfill $\square$

**Proposition 9.5.** For $\pi = (\mathbb{Z}/p \ast G) \times \mathbb{Z}$ as above, the stable isomorphism class of the pair $(\pi_2, k)$ detects the $\mathbb{CP}^2$-stable diffeomorphism type of closed, orientable 4-manifolds with fundamental group isomorphic to $\pi$, but the stable isomorphism class of the second homotopy group does not. That is, there exists a pair of closed 4-manifolds $M$ and, $M'$ with fundamental group $\pi$ such that $\pi_2(M)$ and $\pi_2(M')$ are stably isomorphic but $M$ and $M'$ are not $\mathbb{CP}^2$-stably diffeomorphic.

**Proof.** Let $t: \mathbb{Z}/p \ast G \to \mathbb{Z}/p$ be the projection. Then under the induced map $t_*: \Omega_3(\mathbb{Z}/p \ast G) \to \Omega_3(\mathbb{Z}/p)$ the manifold $X_{p,q}$ becomes bordant to $L_{p,q}$, because $\pi_1(X) = G$ maps trivially to $\mathbb{Z}/p$ under $t$. Cross this bordism with $S^1$ to see that $M_{p,q} = X_{p,q} \times S^1$ is bordant over $\mathbb{Z}/p \times \mathbb{Z}$ to $L_{p,q} \times S^1$.

If the manifolds $M_{p,q}$ and $M_{p,q'}$ are $\mathbb{CP}^2$-stably diffeomorphic, they are bordant over $\pi$, for some choice of identification of the fundamental groups with $\pi$, because both $M_{p,q}$ and $M_{p,q'}$ have signature zero. Therefore the two 4-manifolds are bordant over $\mathbb{Z}/p \times \mathbb{Z}$. Combine this with the previous paragraph to see that $L_{p,q} \times S^1$ is bordant to $L_{p,q'} \times S^1$ over $\mathbb{Z}/p \times \mathbb{Z}$. As we have seen in Section 9.1, this implies that $q = \pm r^2 q'$ mod $p$ for some $r \in \mathbb{N}$ by Proposition 9.2. But there are choices of $p, q$ and $q'$ such that this does not hold, so there are pairs of manifolds in the family \{M_{p,q}\} with the same $p$ that are not $\mathbb{CP}^2$-stably diffeomorphic to one another.

On the other hand, we have $\pi_2(M_{p,q}) = \pi_2(X_{p,q} \times S^1) = \pi_2(X_{p,q})$. By Lemma 9.4, $\pi_2(X_{p,q})$ is independent of $q$. Hence $\pi_2(M_{p,q}) \cong \pi_2(M_{p,q'})$ as $\Lambda$-modules for any $q, q'$ coprime to $p$ with $1 \leq q, q' < p$.

We remark that by Lemma 9.3, we know that Theorem A applies, and so the $k$-invariants must differ for $q$ and $q'$ such that $L_{p,q}$ and $L_{p,q'}$ fail to be homotopy equivalent to one another. \hfill $\square$
