ABSTRACT

Astrocytomas of Conus-Cauda equina region are rare. Astrocytomas, which are intramedullary tumors, may rarely have an extramedullary component. However, primary intradural extramedullary astrocytomas are extremely rare, with very few cases reported in the literature. We describe a giant extramedullary pilocytic astrocytoma of Cauda equina in a 20-year-old male. To the best of our knowledge, this is the first report of such a case in the available literature. This case highlights the fact that astrocytomas can be primarily extramedullary and emphasizes the need to consider pilocytic astrocytoma in the differential diagnosis of cystic Cauda equina tumors.

Key words: Cauda equina, extramedullary, giant, pilocytic astrocytoma

Introduction

Primary spinal cord tumors account for 4-8% of central nervous system tumors. In adults, ependymoma is the most common primary spinal cord tumor followed by astrocytomas, which are rare tumors constituting 6-8% of spinal cord tumors. Cervical and thoracic regions of the spine are the most common locations for spinal astrocytomas to occur, with only 4% of all spinal astrocytomas occurring in the conus-Cauda equina region. It is thus rare for astrocytomas to occur in the Conus-Cauda region, where myxopapillary ependymomas account for 80% of the tumors. Astrocytomas are typically intramedullary tumors and occurrence of a predominantly extramedullary astrocytoma is extremely rare.

We describe such a rare case of giant extramedullary pilocytic astrocytoma of Cauda equina. To the best of our knowledge, giant extramedullary pilocytic astrocytoma of Cauda equina has not been previously described in the available English literature.
Kumar, et al.: Giant pilocytic astrocytoma of the Cauda equina

in the suprasellar region suggestive of hypothalamic glioma [Figure 2].

Patient was operated in the prone position. Midline incision was made. The posterior bony elements were absent in the sacral region. A large intradural cystic lesion, with a thin cyst wall formed by the tumor tissue, was present in the lumbosacral region. The cyst contained xanthochromic fluid. Yellowish, soft, mildly vascular tumor was covering the nerve roots of Cauda equina and the filum terminale. The wall of the tumor and the filum terminale covered with the tumor were removed. The tumor draping the nerve roots was left behind as it entailed the risk of causing neurological deficits.

Figure 1: Cauda equina pilocytic astrocytoma. T1-weighted sagittal (a) and axial (d) images show a hypointense intradural lesion within the spinal canal extending from L4 to S4 spinal segments, causing scalloping of the posterior surface of vertebral bodies and expansion of the canal. In T2-weighted sagittal (b) and axial (e) images, the mass is predominantly hyperintense. The cord is reaching up to L4 vertebral bodies and is low-lying. The mass is not seen separate from the cord. Following contrast administration, mass lesion shows peripheral enhancement (c and f).

Figure 2: Brain magnetic resonance imaging showing associated right acoustic schwannoma (a) and suprasellar contrast enhancing lesion suggestive of hypothalamic glioma (b-d). Screening MRI whole spine did not reveal any other spinal lesion (e).
Post-operative course was uneventful. Patient developed no fresh neurological deficits. Histopathological examination showed features consistent with pilocytic astrocytoma [Figure 3]. As the patient was asymptomatic for intracranial lesions a decision to conservatively follow the patient was taken.

During follow-up, patient’s bladder dysfunction improved gradually and presently patient is able to void himself. However, patient’s motor and sensory symptoms showed neither improvement nor deterioration during 2 years follow-up.

Follow-up MRI revealed recurrence of the lesion [Figure 4]. The intracranial lesions did not increase in size during follow-up. Patient is currently awaiting second surgery.

Discussion

Spinal astrocytomas constitute 6-8% of spinal cord tumors. Only 4% of spinal astrocytomas occur in Conus-Cauda region.[5,6] Spinal astrocytomas can be classified histologically into diffuse fibrillary and pilocytic types.[8] Pilocytic astrocytomas of Conus-Cauda region are very rare. In a study of 79 patients with intramedullary astrocytomas by Minehan et al.[8] none of the patients had pilocytic astrocytoma in the Conus-Cauda region. Rarely astrocytomas may have an exophytic component;[9] however, extramedullary gliomas of Cauda equina region are extremely rare with only few cases reported in the literature[2,10-13] and a giant pilocytic astrocytoma of Cauda equina has not been previously described in the available English literature.

The extramedullary gliomas likely arise from heterotopic nests in pia and arachnoid membranes.[9] Bailey[14] was the first to suggest the glial heterotopias as the site of origin of extramedullary gliomas. Cushing and Eisenhardt[15] first reported an extramedullary spinal glioma. Patient was operated with a clinical impression of meningioma, but histopathology revealed its true identity to be an astrocytoma. In our case also, there was a preoperative diagnostic dilemma with regard to nature of the lesion and a possibility of giant cystic schwannoma was considered, though lack of involvement of foramina was against this diagnosis. The histopathological report surprised us with the diagnosis being pilocytic astrocytoma. This case emphasizes the need to consider pilocytic astrocytoma in the differential diagnosis of cystic Cauda equina tumors.

To the best of our knowledge, this is the first case of a giant Cauda equina pilocytic astrocytoma in the literature; though, there have been few reports of extramedullary astrocytoma of conus region.[10,12,16] Singh et al.[18] reported an extramedullary astrocytoma of conus region with no attachment to surrounding neural structures. It adds another differential in the list of differential diagnoses of cystic Cauda equina lesions.

The management of pilocytic astrocytomas of spinal cord involves surgery with or without adjuvant radiation...
therapy. As these lesions are benign, the patients can be followed-up after surgery and radiation therapy can be given in case of recurrence/regrowth.
