Skull Reconstruction with Custom Made Three-Dimensional Titanium Implant

INTRODUCTION

A cranial bone defect can occur from trauma, infection, and tumor surgery and result in aesthetic and functional deficiencies [1-3]. Depressed scalp or asymmetry of calvaria can affect social relationship. In functional terms, patients can suffer from varied neurologic symptoms like dizziness, irritability, anxiety, and intolerance [2,3].

Background: Source material used to fill calvarial defects includes autologous bones and synthetic alternatives. While autologous bone is preferable to synthetic material, autologous reconstruction is not always feasible due to defect size, unacceptable donor-site morbidity, and other issues. Today, advanced three-dimensional (3D) printing techniques allow for fabrication of titanium implants customized to the exact need of individual patients with calvarial defects. In this report, we present three cases of calvarial reconstructions using 3D-printed porous titanium implants.

Methods: From 2013 through 2014, three calvarial defects were repaired using custom-made 3D porous titanium implants. The defects were due either to traumatic subdural hematoma or to meningioma and were located in parieto-occipital, fronto-temporo-parietal, and parieto-temporal areas. The implants were prepared using individual 3D computed tomography (CT) data, Mimics software, and an electron beam melting machine. For each patient, several designs of the implant were evaluated against 3D-printed skull models. All three cases had a custom-made 3D porous titanium implant laid on the defect and rigid fixation was done with 8 mm screws.

Results: The custom-made 3D implants fit each patient’s skull defect precisely without any dead space. The operative site healed without any specific complications. Postoperative CTs revealed the implants to be in correct position.

Conclusion: An autologous graft is not a feasible option in the reconstruction of large calvarial defects. Ideally, synthetic materials for calvarial reconstruction should be easily applicable, durable, and strong. In these aspects, a 3D titanium implant can be an optimal source material in calvarial reconstruction.

Keywords: Skull / Titanium / Three-dimensional printing
METHODS

From 2013 through 2014, three calvarial defects were repaired using custom-made 3D porous titanium implants by a single reconstructive surgeon at a tertiary academic hospital. The titanium implants were manufactured by Medyssey Company (Dongducheon, Korea) using three-dimensional (3D) computed tomography (CT) data, Mimics software, and an electron beam melting machine (Figs. 1, 2). For each patient and calvarial defect, the engineer and surgeon tried several different implant designs against 3D-printed skull models. Design factors (thickness, fixation type, porosity, etc.) were considered before this step. The final implant design incorporated 2 mm thickness for bone-like rigidity. After manufacturing the 3D implant, we simulated the operation with it to the patient’s rapid prototyping (RP) model. The defects were secondary to traumatic subdural hematoma or meningioma and were located in parieto-occipital, fronto-temporo-parietal, and parieto-temporal areas. Intraoperatively, an incision was made on the scalp and the dissection was made under the periosteum. For each patient, the 3D-printed titanium implant was laid into the defect and rigidly fixed with 8 mm screws.

RESULTS

During the operation, we were able to confirm that the custom-made 3D implants fit each skull defect precisely without any perceptible dead spaces. The operation times were 4 hours 20 minutes, 5 hours 20 minutes and 5 hours. The blood loss was 300 mL, 260 mL, and 300 mL, respectively (Table 1). Scalp depressions were eliminated with return of a more normal contour, and all of the patients expressed satisfaction. Postoperative CT confirmed accurate positioning of the implant. There were no complications.

Case 1

The first patient was a 41-year-old female with a calvarial defect secondary to meningioma resection one year ago. The $12 \times 14$ cm$^2$ defect was located in the left parieto-occipital area and crossed the midline into the right parietal area. Intraoperatively, a coronal incision was made and the dura was exposed. The 3D-printed titanium implant was laid on the skull defect and rigid fixation was done with 8 mm screws. The postoperative follow-up was six months without any complications (Fig. 3).

Case 2

The second patient was a 32-year-old female with a calvarial defect in the right fronto-temporo-parietal area. Due to a subdural hematoma after a traffic accident, she had a craniectomy one year ago. The defect size was $14 \times 11$ cm$^2$. Intraoperatively, a coronal incision was made and the previously inserted implant was removed. Reconstruction was done using the same method as above with 3D titanium implant. The postoperative follow-up was six months without any complications (Fig. 4).

Case 3

The third patient was a 21-year-old female with a calvarial defect in the left parieto-temporal area. She also had a craniectomy two years ago due to an epidural hematoma after a traffic accident. Before then, she previously had a cranioplasty with MedPor at another hospital and the implant had been removed due to infection. The defect size was $15 \times 15$ cm$^2$ and reconstruction was done with a 3D titanium implant. The postoperative follow-up was two months without complications (Fig. 5).

DISCUSSION

In this study, we report three cases successful calvarial reconstruction using custom-made 3D titanium implants. Although the number of cases was small with short follow-up period, custom-made
Implants are highly reasonable options for skull reconstruction. The method has many advantages including shorter operating time, decreased technical demand, and the lack of need for a donor graft.

Autologous bone is widely used in calvarial reconstruction. It has excellent osteoconductive properties and has been the gold standard [7]. However, it requires meticulous harvesting technique. Donor site morbidity is an issue, and bone grafts cannot be used to fill large defects. In some studies, bone resorption has been reported at rates from 3% to 12% [8-10], which often necessitate secondary interventions to compensate for the loss [11,12].

Plastic surgeons have searched for an ideal material to use in skull reconstruction. Such material should be easy to manufacture, be durable, strong, lightweight, non-ferromagnetic, and non-carcinogenic. Materials such as polymethylmethacrylate (PMMA), hydroxyapatite (HA) and polyethylene have proven to be biocompatible but have individual shortcomings. Compared to titanium, PMMA and HA are associated with an increased risk of infection. Polyethylene is not as strong [11,13].

The biocompatibility of titanium is well established [14,15]. It is robust enough to resist secondary trauma while providing maximal stability of the cranial vault. Furthermore, titanium implants generally cause less inflammation and conduct well with surrounding mineralized bone [16]. In a previous experience with porous titanium implants (not custom made), we found tissue ingrowth into the implant. However, these off-the-shelf implants were too hard to be altered during an operation, and it was necessary to be able to prefabricate custom implant using computer-assisted design and manufacturing. Like other metallic implants, it may produce imag-

A major concern in calvarial reconstruction has been the complex geometry which can affect preoperative planning and aesthetic outcomes [17]. With advancement in computer-assisted manufacturing processes, titanium implants could be fabricated using electron beams to print titanium structure in 3D [18]. In our experience, the implants fit the defect precisely without any dead space. A disadvantage of alloplastic materials is its high susceptibility to infection [19]. However, titanium is resistant to bacterial colonization and causes less inflammation. Though our experience represents only three cases, none of the titanium implants became infected during the follow up period. We feel that proper perioperative antibiotic prophylaxis and adequate soft tissue coverage was helpful in minimizing these complications.

In South Korea, the cost of manufacturing custom-made implants is not currently covered by the national health insurance, and the cost borne by patients for each implant was expensive. In Europe, the costs of implants range from €2500 to €5050 (mean, €3733) [20]. Despite this, patients were satisfied with the choice to receive custom titanium implants and did not complain regarding the cost of implant.

The limitations of this study are small sample size and lack of long-term follow-up data. Although there are no early complications and patients remain satisfied, long-term follow up is needed for signs of infection and impaired wound healings as reported in previously published cases [20]. The ideal material for skull reconstruction remains controversial [20]. Biomechanical stability, cerebral protection, and cosmetic outcome are significant factors to consider when selecting a source material. In these aspects, custom-made 3D titanium implants can be a great option for skull reconstruction.
