Abstract: The anion and cation deficient phase Bi$_{19.95}$In$_{0.05}$O$_{5.5}$ (Bi$_{1.5}$In$_{0.1}$O$_3$) was synthesized and experimentally investigated using X-ray diffraction and vibrational spectroscopy (Infrared and Raman). The non-stoichiometric phases are similar to sillenite family type γ-Bi$_2$O$_3$ and crystallize in the I23 space group. The crystal structure was determined by full profile Rietveld analysis of the powder diffractogram. It is formed by a sequence of BiO$_2$E polyhedra (E lone pair of bismuth) and MO$_4$ polyhedra (M = In, Mg). The set of MO$_4$ polyhedra are localized in cavities generated by BiO$_2$E polyhedra. The vibrational spectroscopic study revealed the existence of three regions; low, intermediate and high-frequency region. They are attributed to Bi-O stretching mode, In / Mg-O vibrations and cationic displacements respectively.

Key words: Sillenite; X-ray diffraction; IR; RAMAN.

1. Introduction

Recently, materials having elements with outer electronic configuration ns$^2$, particularly sillenite phases, have been extensively studied because of their remarkable properties such as; piezoelectricity, optoelectronics, photocatalysis, dielectricity ... 1-8.

Indeed the sillenite phase is isolated for the first time by Silen in 1937 and admits as formula Bi$_{12}$MO$_{20}$ (M= Si, Ti, Ge) 9. Several studies have been conducted, in particular on the crystalline structure, such as those of Levin and Roth 10, and Radev et al. 11 that have determined the crystal structure of Bi$_{12}$ (Bi$_{2/3}$Zn$_{1/3}$) O$_{19.33}$ and Bi$_{12}$ (Bi$_{3/4}$Fe$_{1/4}$)O$_{19.5}$ by neutron diffraction.

The stability of sillenite phase is achieved by adding small amounts of desired oxides such as Li$_2$O, ZnO, Ga$_2$O$_3$, As$_2$O$_3$, P$_2$O$_5$, V$_2$O$_5$...without exceeding 8 mol% 12,13. Generally, sillenites are stoichiometric or sub-stoichiometric. The defects appear in both cationic and anionic sub-lattices 14. Several structural models were established 15. The models proposed by Radev et al and confirmed later by J.C Champarnaud 16,17 seem more convincing. These models revealed that sillenite is related to the γ-Bi$_2$O$_3$ variety and is written as Bi$_{12}$ ((BiO)$_{0.8}$ (InO)$_{0.2}$) O$_{16}$ =Bi$_{12}$ Bi$_{0.8}$ O$_{19.2}$.

The sillenite compounds Bi$_{12}$ M$_x$O$_{2x}$ crystallize in the I23 space group. The crystalline structure is formed by a three-dimensional sequence of BiO$_2$E polyhedra (E lone pair). These polyhedra share the edges and the vertices by M$^{2+}$O$_4$ tetrahedra. The M$^{2+}$ cation may be a tetravalent element in the case of stoichiometric sillenite or a combination of elements with an average value of four.

In the present work, On the one hand, the new phases isolated within the Bi$_2$O$_3$-In$_2$O$_3$-MgO system have been studied and identified as belonging to sillenite family. On the other hand, these phases were examined using Infrared and Raman spectroscopy techniques. The X-ray analysis was performed using the Rietveld structure refinement by full prof program 18. The influence of dopant content; indium (single doping) or In and Mg (codoping) on the sillenite structural features has been discussed.

2. Experimental section

2.1. Preparation

The synthesized compounds have been stabilized with a solid-state method using the appropriate quantities of highly pure oxides powder α Bi$_2$O$_3$, MgO and In$_2$O$_3$ with high purity (Aldrich brand). These oxides were heated at successively higher temperatures 700°C (24h) and 800°C (24h) with several intermediate grindings and followed by quenching.

2.2. X-ray diffraction

The final products have been monitored by X-ray powder diffraction (XRD) using a Philips X’Pert PRO

DOI: http://dx.doi.org/10.13171/mjc10120011123hao
diffractometer and Cu-K-alpha (λ=1.5406Å) radiation. The structural refinements were undertaken from the powder data. The patterns were scanned through steps of 0.02° (2θ), between 10° and 70° (2θ) with a fixed time counting of 60 s. The study of the structure is conducted by analyzing the profile of X-ray diffraction diagrams of powder with the program Fullprof 18 using the pseudo-Voight function.

2.3. IR spectrum
IR spectrum was recorded by using Bruker Tensor 27 with prepared pellets (1mg + 99mg KBr) in a frequency range of 400-4000 cm⁻¹.

2.4. Raman Spectrum
Raman spectrum was recorded by using DXR RAMAN spectrometer with exciter wavelength of 663nm and a power of 6 MW.

3. Results and discussion
3.1. Structural studies
In this paper, the structural analysis was focused on three compositions, namely Bi₀.⁹₅ In₀.₀₅ O₁.₅, Bi₀.⁹₀In₀.₀₅Mg₀.₀₅O₁.₄₇₅ and Bi₀.₈₀In₀.₁₅Mg₀.₁₅O₁.₄₅. We present Bi₀.⁹₅ In₀.₀₅ O₁.₅ (Bi₁.₉ In₀.₁ O₃) as an example. The results of the other compositions will be published later.

On the basis of γBi₂O₃ phase structure previously determined by Radev¹¹, we carried out our structural study by distributing the cations on the possible sites. The chemical form of this compound can be written: Bi₁₂ [(Bi₀.₁₆ In₀.₆₄) □ O₃] ₀.₈ (□O₄)₀.₂ O₁₆. Table 1 contains the experimental conditions and the structural parameters of this composition.

- **First case:**
  Bi₁ → 24f, Bi₂, In →2a, O₁ →24f, O₂ →8c, O₃ →8c
  Many refinement cycles are performed and lead to good reliability values (Table 1). However, the calculated distances of coordination polyhedra are incorrect.

- **Second case:**
  Bi₁ → 24f, In →2a, O₁→24f, O₂→8c, O₃→8c
  The final refinement led to an occupancy rate of Bi atom >1 on 24f site, which contradicts the total filling on this site.

- **Third case:**
  The atoms Bi and In, initially occupying the sites 24f and 2a respectively (according to the first case), were redistributed in the nearby sites admitting, therefore, the atomic positions given in Table 2.

The final refinement seems to be in good agreement with the occupancy rates and the calculated distances (Tables 2 and 3).

3.2. Structure
The structure of Bi$_{0.95}$In$_{0.05}$O$_{1.5}$ (Bi$_{1.9}$In$_{0.1}$O$_3$) is illustrated in Figure 2.

Figure 2. Three-dimensional view of Bi$_{0.95}$In$_{0.05}$O$_{1.5}$

Note: We have simplified the structure representation by placing In/Bi2 on the same site.

Figure 3. The octahedral arrangement of Bi$_{3+}$ with five atoms of oxygen and the lone pair of bismuth

Figure 4. View of the In$_{3+}$ environment
Figure 5. View of the Bi$_2^{3+}$ environment

Figure 6. Three-dimensional environment of octahedron Bi$_1$O$_3$E and tetrahedron (In/Bi$_2$) O$_4$
The structure consists of a three-dimensional sequence of BiO$_3$E (E lone pair) polyhedra (Fig.3) stereochemically active of Bi$^{3+}$ sharing alternatively edges and vertices.

This lattice system contains tetrahedral cavities occupied by Bi$^{3+}$/ In$^{3+}$. The substitution of bismuth by indium of a smaller size will cause a decrease of lattice parameter a ($\gamma$ Bi$_2$O$_3$ = 10.25Å) to 10.10Å.

Some changes have been observed in this structure in comparison with the ideal sillenite structure Bi$_{12}$MO$_{20}$ (Bi$_{12}$SiO$_{20}$) (Fig.7).

These modifications are manifested by a mutual displacement of Bi and In atoms and also oxygen atoms located in the equatorial plane of BiO$_3$E polyhedra (Fig. 6). Three types of polyhedra surrounding Bi$^{3+}$ (24f site) are envisaged.

- **Bi$_4$O$_3$E** environment (Fig.3) is a distorted polyhedra. Bi-O distances vary from 2.02 Å to 2.88Å; the average distance Bi-O is of the order of 2.43Å as established by Shannon 20 RBi$^{3+}$+ RO$^2$=$1.03+1.40$ Å.

- **Bi$_2$O$_4$ and InO$_4$** polyhedra: This type of polyhedron is similar to that encountered for many compounds of sillenite structure 21. Bi$_3$ atom is surrounded by 4 oxygens at distances varying between 1.93Å and 2.04Å (Fig.5). The longest distance Bi-O leads to a modification of the lone pair E orientation on the one hand and the environment of the connected coordination polyhedra on the other hand.

The Bi/In environment is a regular tetrahedra, as shown in Figures 5 and 6, the In-O$_x$ distance is 1.95Å. The distribution of Bi$^{3+}$/In$^{3+}$ on the tetra 8c and 2a sites, respectively, generates the creation of anionic vacancies. If this bond is excluded, the environment Bi$_2$O$_3$ E will be surrounded by three oxygens and E. The lone pair E is directed to the missing vertex of the Bi$_2$O$_3$ E tetrahedra.

Furthermore, the existence of anionic and cationic vacancies in 8c site leads to changes in bond lengths within the polyhedra in Bi$_{12}$O$_{16}$ lattice. In Table 4, we have grouped the main distances obtained in certain sillenite phases (Bi$_{12}$GeO$_{20}$ and $\gamma$Bi$_2$O$_3$) compared to the distance of the new phase isolated in the Bi$_{12}$O$_{20}$ In$_{0.05}$ – MgO system.

|         | Bi$_2$GeO$_{20}$ | $\gamma$Bi$_2$O$_3$ | Bi$_{10.95}$In$_{0.05}$O$_{1.5}$ |
|---------|------------------|---------------------|----------------------------------|
| Bi-O1   | 2.072            | 2.045               | 2.023                            |
| Bi-O1   | 2.221            | 2.402               | 2.423                            |
| Bi-O1   | 2.622            | 2.456               | 2.523                            |
| Bi-O2   | 2.2141           | 2.2788              | 2.216                            |
| Bi-O3   | 2.6241           | 2.561               | 2.535                            |

**3.2. Raman spectroscopy analysis**

Raman spectrum of the crystal Bi$_{10.95}$In$_{0.05}$O$_{1.5}$ is illustrated in Figure.8. We have also reported the Raman spectrum of Bi$_{12}$TiO$_{20}$ as a comparison (Table 5). The spectrum was recorded in 100-800 cm$^{-1}$ spectral range at room temperature. The attribution of Raman peaks was based on previous work 22. At first glance, the spectra are broadly comparable to the Bi$_{12}$TiO$_{20}$ spectrum with a slight difference in intensities. This difference seems to be due to the doping elements In and Mg on the one hand and the other hand, to the interaction of BiO$_3$ polyhedra with their counterparts In / Mg O$_x$.

| 11            | 616.30                           | E             | Stretching vibrations O$_3$ and weak Bi-O$_1$ and Bi-O$_2$ rocking |
| 12            | 818.59                           | FTO           | Antisymmetric stretching vibration of TiO$_4$ tetraedra |

Indium oxide usually absorbs 800-300 cm$^{-1}$ radiation $^{23}$. In our compound (Fig.8), a peak at 818.59 cm$^{-1}$ is actually observed and therefore attributed to the In-O$_4$ tetrahedra.

The shoulder observed at about 368.15 cm$^{-1}$ is probably assigned to Bi-O-In bonds because the mass of bismuth is higher than that of indium. As a result, the oscillations of In-O$_4$ tetrahedra are small.

Peaks observed at 117.24 and 301.82 cm$^{-1}$ frequency are due to symmetrical vibrations of Bi-O$_1$/O$_2$.

Peaks below 616.30 cm$^{-1}$ are mainly attributed to Bi-O vibrations. The set of frequency attributions observed is shown in Table 5. In agreement with the crystalline structure, the MO$_4$ tetrahedra are surrounded by 12 Bismuth atoms, and thus the displacements of these tetrahedra are weak.

It seems that the IR mode relating to bismuth (high mass) must indeed move to the low frequencies; it is not indistinguishable from other lattice vibrations. The constant force Bi-O is therefore strong. Moreover, the frequencies $\nu$3 of the InO$_4$ and BiO$_4$ tetrahedra are lowered approximately by 50 cm$^{-1}$ to those observed in ions. This effect is attributed to the existence of Bi-O-In bonds with tetrahedral sites by $\text{M}^{3+}$.

Figure 8. Raman spectrum of Bi$_{0.95}$ In$_{0.05}$ O$_{1.5}$
3.3. Infrared spectroscopy analysis
IR spectrum of the crystal Bi$_{0.95}$In$_{0.05}$O$_{1.5}$ is illustrated in the Figure. 9. The significant band frequencies of Bi$_{0.95}$ In$_{0.05}$ O$_{1.5}$ are given in Table 6. The bands observed between 467.49 and 633.34 cm$^{-1}$ are attributed to Bi-O vibration modes. The one that appeared at 831.91 cm$^{-1}$ is assigned to the Bi-O-Bi vibration modes.

4. Conclusion
The results of structural refinements are in perfect agreement with those determined by$^{16,17}$ on sillenite compounds. The structure is formed by a sequence of BiO$_5$ polyhedra linked together by edges. These polyhedra are connected by Bi/InO$_4$ tetrahedra via O$_3$ atoms.

The phases are non-stoichiometric on both the anion and cation sublattice. They are similar to γBi$_2$O$_3$ type sillenite phase. The substitution of Bi by In of a smaller size causes a lattice parameter decrease. Three regions are elucidated by the vibrational spectroscopic study. The low-frequency region is attributed to cations displacement, the second region, which corresponds to medium frequencies, is attributed to stretching vibration modes of Bi-O however, the high frequencies (observed in the third region) are assigned to the deformation bonds of Bi / In - O-Bi.
