Abstract

We study the inviscid limit problem of incompressible flows in the presence of both impermeable regular boundaries and a hypersurface transversal to the boundary across which the inviscid flow has a discontinuity jump. In the former case, boundary layers have been introduced by Prandtl as correctors near the boundary between the inviscid and viscous flows. In the latter case, the viscosity smoothes out the discontinuity jump by creating a transition layer which has the same amplitude and thickness as the Prandtl layer. In the neighbourhood of the intersection of the impermeable boundary and of the hypersurface, interactions between the boundary and the transition layers must then be considered. In this paper, we initiate a mathematical study of this interaction and carry out a strong convergence in the inviscid limit for the case of the plane-parallel flows introduced by Di Perna and Majda (1987 Commun. Math. Phys. 108 667–89).

Mathematics Subject Classification: 35Q30

1. Introduction

In this paper we are interested in the behaviour of incompressible Navier–Stokes flow when the viscosity is small. This so-called inviscid limit problem is particularly difficult when the flow is contained in a domain limited by impermeable walls. In the standard case of a half-space, the problem reads as follows:

\begin{equation}
\begin{aligned}
\partial_t \mathbf{v}^\epsilon + (\mathbf{v}^\epsilon \cdot \nabla) \mathbf{v}^\epsilon + \nabla p^\epsilon &= \frac{\epsilon}{\Delta} \mathbf{v}^\epsilon \\
\text{div} \mathbf{v}^\epsilon &= 0.
\end{aligned}
\end{equation}

(1.1)
Here, \( x = (x, y, z) \) is in \( \mathbb{R} \times \mathbb{R} \times (0, +\infty) \), the velocity \( \mathbf{v}^\epsilon = (u^\epsilon, v^\epsilon, w^\epsilon) \) is in \( \mathbb{R}^3 \), \( p^\epsilon \) the kinematic pressure and \( \epsilon > 0 \) is the viscosity parameter.

Equation (1.1) is imposed with the classical no-slip boundary condition:

\[
\mathbf{v}^\epsilon_{|z=0} = 0. \tag{1.2}
\]

Considering the problem (1.1) and (1.2) in the limit \( \epsilon \to 0 \), one may hope to recover the Euler flow: equation (1.1) with \( \epsilon = 0 \), for which the natural condition on the boundary \( \{z = 0\} \) is

\[
u^0_{|z=0} = 0. \tag{1.3}
\]

Due to the difference (or rather, loss) of boundary conditions, it is common in the limit to add a boundary corrector or the so-called Prandtl layer. This formal procedure was introduced by Prandtl in 1904, and it remains a challenging mathematical problem to determine the domain of validity of this theory.

Nonetheless, some positive answers have been given in the setting of analytic flows by Caflish and Sammartino [13, 14] and improved by Cannone et al [15] for inviscid flows that are analytic with respect to the tangential variables. On the other hand, when the smoothness with respect to the tangential variables is limited, the Prandtl layer has been shown to be unstable; see for example [5–8]. Note that these papers also concern the 2D case.

Here, we propose to study the inviscid limit problem of a viscous incompressible Navier–Stokes flow in the presence of both a solid boundary and a transversal discontinuity hypersurface in the limiting inviscid flow. The full problem is currently out of reach. In particular, jump discontinuity across a hypersurface is also a rather unstable pattern for the incompressible Euler equations, because of the Kelvin–Helmholtz instabilities. Nevertheless, when the inviscid theory is successful in providing some Euler solutions with some jump discontinuity across a hypersurface, it is expected that the extra viscosity in the Navier–Stokes solutions smoothes out the discontinuity into a transition layer which can be basically thought of as a transmission version of the Prandtl layers. Here again, positive results are known in an analytic framework, in 2D, see [3].

However, since this hypersurface is assumed here to be transverse to the boundary, one cannot rely on the previous results based upon the analyticity in the transversal variables to study the interactions between the boundary layer and the transition layer. We will therefore study interactions of the layers in Sobolev spaces.

In this paper, we will restrict our study to a simple setting of three-dimensional incompressible flows: the plane-parallel flows. They were introduced by DiPerna and Majda [4] in order to prove that the Euler equations are not closed under weak limits (in three spatial dimensions). These flows have also been used as basic flows for the Euler equations by Yudovich [17] to investigate stability issues and by Bardos and Titi [1] to investigate several long-standing questions including the minimal regularity needed to have well-posedness results, localization of vortex sheets on surfaces and energy conservation for the Euler equations. Recently, Bardos et al also use [2] these same flows to nominate the vanishing viscosity limit as a uniqueness criterion for weak solutions of the Euler equations.

Precisely, a plane-parallel solution is of the form

\[
\mathbf{v}^\epsilon(t, x, y, z) = \begin{pmatrix}
   u^\epsilon(t, z) \\
   v^\epsilon(t, x, z) \\
   0
\end{pmatrix}. \tag{1.4}
\]

Then, the Navier–Stokes system (1.1) depletes into

\[
\begin{align*}
\partial_t u^\epsilon &= \epsilon \partial_z^2 u^\epsilon \\
\partial_t v^\epsilon + u^\epsilon \partial_x v^\epsilon &= \epsilon \Delta v^\epsilon,
\end{align*} \tag{1.5}
\]
with \( \rho^e = 0 \). It is thus a pressureless flow. Observe that a vector field of the form (1.4) is divergence free. On the other hand the boundary conditions (1.2) now read
\[
(u^e, v^e)_{|z=0} = 0,
\]
as the Dirichlet condition for the third component is automatically satisfied for flows of the form (1.4). The system (1.5) and (1.6) is now quite simple: the first equation in (1.5) is a one-dimensional heat equation whereas the second one is a two dimensional transport–diffusion equation, and for both we prescribe homogeneous Dirichlet conditions.

On the other hand, the Euler system, the equations (1.1) with \( \epsilon = 0 \), depletes into
\[
\begin{align*}
\partial_t u^0 & = 0 \\
\partial_t v^0 + u^0 \partial_x v^0 & = 0.
\end{align*}
\]
Therefore the solution starting from the initial data
\[
v_0(x, z) = \begin{pmatrix} u_0(z) \\ v_0(x, z) \\ 0 \end{pmatrix}
\]
is simply given by the formula
\[
v^0(t, x, z) = \begin{pmatrix} u_0(z) \\ v_0(x - t u_0(z), z) \\ 0 \end{pmatrix}.
\]
This holds true in a quite general setting, but let us be formal for a few more lines. For instance let us think that the function \( v_0 \) is smooth for a while, so that there is no doubt about the meaning of the formula (1.8) nor about the fact that it solves the depleted Euler equations (1.7). We first want to focus on the issue of the boundary conditions. In particular, note that no boundary conditions need to be prescribed for the system (1.7), since any solution of the form (1.4) already satisfies the condition (1.3). On the other hand, if the initial data \( v_0 \) does not vanish on the boundary \( z = 0 \) then neither does the corresponding solution \( v^0 \) given by (1.8) for positive times. As a consequence, \( v^0 \) does not satisfy the condition (1.6) and therefore cannot be a good approximation, say in \( L^\infty \), of any smooth solution \( v^e \) of the system (1.5) and (1.6). Yet Prandtl’s theory predicts that the system (1.5) and (1.6) admit some solutions \( v^e \) which have the following asymptotic expansion as \( \epsilon \to 0 \):
\[
v^e(t, x, z) \sim v^0(t, x, z) + v_P \left( t, x, \frac{z}{\sqrt{\epsilon}} \right).
\]
Above the profile \( v_P(t, x, Z) \) describes a Prandtl boundary-layer correction. In particular it satisfies \( v_P(t, x, Z) \to 0 \) when \( Z \to +\infty \), so that this term really matters only in a layer of thickness \( \sqrt{\epsilon} \) near the boundary \( \{ z = 0 \} \), and also satisfies \( v^0(t, x, 0) + v_P(t, x, 0) = 0 \), so that the functions in the right hand side of (1.9) satisfy the boundary conditions (1.6). The validity of this asymptotic expansion has been verified in a recent paper by Mazzucato et al [10] for regular initial data \( v_0 \), see also [11, 12]. In particular it follows easily from their analysis that for any regular initial data \( v_0 \), there exists a sequence of smooth solutions \( v^e \) of the system (1.5) and (1.6), with some initial data conveniently chosen, such that \( v^e \) converges to \( v^0 \) strongly in the \( L^2 \) topology.

Here, as mentioned previously, we are interested in the case where \( v_0 \) has a jump of discontinuity across a hypersurface. More precisely we assume that \( u_0 \) is smooth and that \( v_0 \) is piecewise smooth with a jump of discontinuity across the hypersurface \( \{ x = 0 \} \):
\[
[v_0]_{|x=0} := \lim_{x \to 0^+} v_0(x, z) - \lim_{x \to 0^-} v_0(x, z) \neq 0.
\]
We assume for simplicity that there is no jump of the normal derivative of \(v_0\) across the hypersurface \(\{x = 0\}\), that is
\[
[\partial_x v_0]_{1;0} = 0.
\] (1.11)

Then it can be easily seen on the formula (1.8) that the corresponding Euler solution \(v^0\) is piecewise smooth with a jump of discontinuity across the hypersurface given by the equation \([\Psi^0(t, x, z) = 0]\), with
\[
\Psi^0(t, x, z) := x - \tau(t, z), \quad \tau(t, z) := tu_0(z),
\]
Moreover taking the derivative with respect to \(x\) of the both sides of formula (1.8) yields that there is no jump of the normal derivative of \(v_0\) across the hypersurface \([\Psi^0(t, x, z) = 0]\).

Such a pattern cannot hold anymore for any reasonable solutions \(v^\epsilon\) of the depleted Navier–Stokes equations (1.5) and (1.6): the viscosity smoothes out this jump of discontinuity into a transition layer near the hypersurface \([\Psi^0 = 0]\). In particular \(v^\epsilon\) and its normal derivative must be continuous across the hypersurface \([\Psi^0 = 0]\) so that the following Rankine–Hugoniot conditions hold:
\[
[v^\epsilon]_{\Psi^0=0} = 0 \quad \text{and} \quad [\partial_x v^\epsilon]_{\Psi^0=0} = 0.
\] (1.12)

Following Prandtl’s ideas it is natural to introduce a corrector
\[
v_{KH}^\epsilon \left( t, \frac{\Psi^0(t, x, z)}{\sqrt{\epsilon}}, z \right)
\]
where the profile \(V_{KH}(t, X, z)\) satisfies\(^4\)
\[
\begin{cases}
[V_{KH}]_{X=0} = -[v_0]_{x=0} \\
[\partial_X V_{KH}]_{X=0} = 0,
\end{cases}
\] (1.13)
and \(V_{KH} \to 0\) as \(X \to \pm \infty\). This strategy can be seen as a transmission counterpart of the introduction of the boundary layer \(v_P\) previously mentioned. Actually, if the fluid domain was not limited by the boundary \(\{z = 0\}\) one could then adapt the analysis of [10] to justify the existence of some solutions \(v^\epsilon\) of (1.5) and (1.6) which admit an expansion of the form
\[
v^\epsilon(t, x, z) \sim v^0(t, x, z) + v_{KH} \left( t, \frac{\Psi^0(t, x, z)}{\sqrt{\epsilon}}, z \right).
\]

Yet there is no reason why the transition layer \(v_{KH}\) should satisfy the boundary condition at \(z = 0\), nor why the boundary layer \(v_P\) should take care of the jump condition across \([\Psi^0 = 0]\). It is specifically our aim to understand how to deal with both layers.

Our result is the following.

**Theorem 1.1.** Let \(1 < p < 2\) and let
\[
\begin{align*}
\varphi_0(z) &\in H^2(0, +\infty), \\
v_{0,+}(x, z) &\in W^{2,p}(0, +\infty) \times (0, +\infty), \\
v_{0,-}(x, z) &\in W^{2,p}((-\infty, 0) \times (0, +\infty)),
\end{align*}
\] (1.14)
and
\[
v_0 \in L^p(\mathbb{R} \times (0, +\infty)), \quad \text{with} \quad v_0(x, z) := \begin{cases} v_{0,+}(x, z), & x > 0, \\
v_{0,-}(x, z), & x < 0. \end{cases}
\] (1.15)

Assume that \(v_0\) satisfies the jump conditions (1.10) and (1.11). Let us consider \(v^0\) given by the formula (1.8), which for any \(T > 0\) is a distributional solution of the depleted Euler equations (1.7) with \(v^0_{1;0} = v_0\).

\(^4\) Here the subscript \(KH\) holds for Kelvin–Helmholtz.
Then, there exist some smooth solutions \( v^\epsilon := (u^\epsilon(t, z), v^\epsilon(t, x, z)) \) of the depleted Navier–Stokes equations (1.5) and (1.6) such that as \( \epsilon \to 0 \), there holds the strong convergence
\[
v^\epsilon \to v^0 \quad \text{in } L^\infty(0, T; L^2(\mathbb{R}_+) \times L^p(\mathbb{R} \times \mathbb{R}_+)).
\] (1.16)

Here \( W^{2,p}_{\text{reg}} \) denotes the usual Sobolev space of order 2 associated to the Lebesgue space \( L^p \) and \( H^2 \) denotes the special case \( H^2 := W^{2,2}_{\text{reg}} \).

Let us end our introduction with a few comments. First, we note that the inviscid limit is obtained as a strong convergence (1.16) in \( L^p \) norm. The regularity of initial data might not be optimal for the strong convergence, but is required for the asymptotic expansions in our analysis.

Next, notice that in the statement of theorem 1.1 the initial data of \( v^\epsilon \) is not prescribed. In the proof, we will explicitly choose them in a convenient way; in particular, it allows the boundary and transmission layers to be initially specified. This could perhaps seem a little bit unusual at first glance, but it is in fact only technical for our convenient formulation of the main result. However this way of formulating our results avoids some extra considerations regarding forcing terms and/or initial layers which do not seem essential for our purposes in this paper.

Let us point out that we are unable to include the case \( p = 2 \) or any \( p > 2 \) in theorem 1.1. We will explain why in remark 3.7.

Finally let us mention the closely related issue of the interaction between shock and boundary layers for which the triple-deck theory provides a nice asymptotic description; see, for e.g., [16]. There the interaction is studied mainly through three interaction regions (decks) with different sizes of thickness. In our current setting, we provide an asymptotic description specifically in the main deck with the size of square root of the viscosity.

2. Straightened interface

To fix the interface, we introduce the following change of variable:
\[
\tilde{x} := x - \psi(t, z), \quad \text{where } \psi(t, z) := tu_0(z).
\]
In these coordinates, the discontinuity interface is given by the equation \( \tilde{x} = 0 \). In what follows, we drop the tilde in \( \tilde{x} \). The system (1.5) now reads
\[
\begin{align*}
\partial_t u^\epsilon & = \epsilon \Delta_{\tilde{x}} u^\epsilon, \\
\partial_t v^\epsilon + (u^\epsilon - u_0)\partial_x v^\epsilon & = \epsilon \Delta_{\tilde{x}} v^\epsilon,
\end{align*}
\] (2.1)
with
\[
\Delta_{\tilde{x}} := \partial_{\tilde{x}}^2 + (\partial_{\tilde{z}} - \partial_z \psi \partial_x)^2 = (1 + |\partial_z \psi|^2) \partial_{\tilde{x}}^2 - 2 \partial_z \psi \partial_{\tilde{x}} \partial_x - \partial_{\tilde{x}} \partial_x + \partial_z^2.
\]

The boundary conditions (1.6) do not change:
\[
(u^\epsilon, v^\epsilon)_{|_{z=0}} = 0.
\] (2.2)

We are looking for some functions \( u^\epsilon \) and \( v^\epsilon \) which satisfy equations (2.1) on both quadrants \( (x, z) \in (0, +\infty) \times (0, +\infty) \) and \( (x, z) \in (-\infty, 0) \times (0, +\infty) \) with the interface conditions:
\[
[v^\epsilon]_{x=0} = 0 \quad \text{and} \quad [\partial_x v^\epsilon]_{x=0} = 0,
\] (2.3)
which correspond to the conditions (1.12) in the new variables. Now, since \( u^\epsilon \) does not depend on \( x \), the conditions (2.3) reduce to
\[
[v^\epsilon]_{x=0} = 0 \quad \text{and} \quad [\partial_t v^\epsilon]_{x=0} = 0.
\] (2.4)
Note that if \( u^\epsilon \) and \( v^\epsilon \) are distributional solutions of (2.1) on both quadrants \((x, z) \in (0, +\infty) \times (0, +\infty)\) and \((x, z) \in (-\infty, 0) \times (0, +\infty)\) and satisfy the previous interface conditions then they are distributional solutions of (2.1) on the whole half-space \( \mathbb{R} \times (0, +\infty) \).

In the limit case \( \epsilon = 0 \), the situation is now particularly simple: in the new coordinates the solution \( v^0 \) is stationary

\[
\begin{pmatrix}
u^0(t, x, z) \\
v^0(t, x, z)
\end{pmatrix} = \begin{pmatrix}u_0(z) \\
v_0(x, z) \\
0
\end{pmatrix}.
\]

(2.5)

Now, to prove theorem 1.1 it suffices to prove that there exist some functions \( u^\epsilon \) and \( v^\epsilon \) which satisfy equations (2.1) on both quadrants, satisfy the conditions (2.2) and (2.4) and converge, as \( \epsilon \to 0 \), to \( v^0 \) given by (2.5) in \( L^\infty(0, T; L^2(\mathbb{R} \times \mathbb{R}_+)) \times L^p(\mathbb{R} \times \mathbb{R}_+) \).

3. Asymptotic expansions

Let us now describe our strategy. We are going to construct a family of functions of the form

\[
\begin{align*}
u^\epsilon(t, z) &= u_0(z) + U_p \left( t, \frac{z}{\sqrt{\epsilon}} \right), \\
v^\epsilon(t, x, z) &= v_0(x, z) + V_P \left( t, \frac{x}{\sqrt{\epsilon}}, z \right) + V_H \left( t, \frac{x}{\sqrt{\epsilon}}, z \right) + V_b \left( t, \frac{x}{\sqrt{\epsilon}}, z \right),
\end{align*}
\]

(3.1)

which satisfy approximately (2.1) on both quadrants (in a sense that will be precise in the sequel), and which satisfy the conditions (2.2) and (2.4).

In (3.1), \((u_0, v_0)\) are the functions given by (2.5). The other functions will be defined in the sequel. For instance, \((U_p, V_p)\) will be a depleted Prandtl layer near the boundary, \(V_H\) will be a transmission layer near the discontinuity interface, and \(V_b\) will aim at describing the behaviour of the boundary-layer and internal layer interaction. In what follows, we will use, as in the introduction, the capitalized variables \(X, Z\) to refer to \(x/\sqrt{\epsilon}, z/\sqrt{\epsilon}\), correspondingly.

Then we will prove that there exists a family of functions \((u^\epsilon, v^\epsilon)\) close to \((u^\epsilon_{app}, v^\epsilon_{app})\) which exactly satisfy (2.1) on both quadrants and \((x, z) \in (-\infty, 0) \times (0, +\infty)\), and which still satisfy the conditions (2.2) and (2.4).

It remains to prove that this family \((u^\epsilon, v^\epsilon)\) converges to \((u_0, v_0)\) in \(L^\infty(0, T; L^2(\mathbb{R} \times \mathbb{R}_+)) \times L^p(\mathbb{R} \times \mathbb{R}_+)\), for \(1 < p < 2\), in order to conclude the proof of theorem 1.1.

3.1. Construction of the approximated solution

3.1.1. Construction of \(U_p\). We start by defining the function \(U_p\), which aims at compensating the non-vanishing value of \(u_0\) at \(z = 0\). On the other hand, we want this correction to be localized near the boundary \(z = 0\). We will therefore require \(U_p\) to satisfy

\[
U_p(t, 0) = -u_0(0), \quad \lim_{Z \to +\infty} U_p(t, Z) = 0.
\]

(3.2)

Now if we put the ansatz (3.1) into the system (2.1) and match the order in \(\epsilon\), we get from the equation for \(u^\epsilon\) the following equation for the profile \(U_p(t, Z)\):

\[
\partial_t U_p = \partial_z^2 U_p.
\]

(3.3)

We choose for \(U_p\) the initial value

\[
U_p|_{t=0}(Z) = -u_0(0) e^{-Z}.
\]

(3.4)

By Duhamel’s principle, the solution \(U_p(t, Z)\) of (3.2)–(3.4) satisfies

\[
U_p(t, Z) = -u_0(0) e^{-Z} - u_0(0) \int_0^t \int_0^{+\infty} G(t-s, Z; Z') e^{-Z'} dZ' ds,
\]
Lemma 3.1. There exists a unique solution $V_p$ representation for $s$ satisfies the similar integral representation to that of $V_p$ where $G$.

Now by using the standard convolution inequality: $\| f \ast g \|_{L^p} \leq \| f \|_{L^p} \| g \|_{L^1}$, we easily deduce that, for any $p > 1$,

$$\| U_p \|_{L^\infty(0,T; L^p(\mathbb{R}_+))} \leq C_0|u_0(0)|\left[1 + \int_0^T \| G(t, \cdot) \|_{L^1} e^{-Z} \|_{L_p} ds \right] \leq C_0|u_0(0)|,$$

for some positive constant $C_0$ that depends on $p$ and $T$. Here, we used the fact that $\| G(t, \cdot) \|_{L^1} = 1$. Similarly, using the fact that $\| \partial_z G(t, \cdot) \|_{L^1} \sim t^{-1/2}$, we obtain

$$\| \partial_z U_p \|_{L^\infty(0,T; L^p(\mathbb{R}_+))} \leq C_0|u_0(0)|\left[1 + \sup_{0 \leq t \leq T} \int_0^\infty (t-s)^{-1/2} ds \right],$$

which is again bounded by $C_0|u_0(0)|$.

That is, we obtain the following lemma:

**Lemma 3.1.** There exists a unique solution $U_p$ to the problem (3.2)–(3.4) on $[0, T] \times \mathbb{R}_+$, for any $T > 0$. Furthermore, for any $p > 1$, there is some positive constant $C_0$ that depends on $p$ and $T$ such that

$$\| U_p \|_{L^\infty(0,T; W^{s,p}(\mathbb{R}_+))} \leq C_0|u_0(0)|. \tag{3.6}$$

3.1.2. Construction of $V_p$. For $V_p$, the situation is the same as that for $U_p$, other than the fact that $V_p$ also depends on the variable $x$. However, $x$ only appears as a harmless parameter. More precisely, by plugging the ansatz (3.1) into the system (2.1) and matching the order in $\epsilon$, we then get from the equation for $v^\epsilon$ the profile equation for $V_p(t, x, Z)$:

$$\partial_t V_p = \partial_x^2 V_p, \quad V_p|_{z=0} = -v_0(x, 0), \quad \lim_{Z \to \pm \infty} V_p = 0. \tag{3.7}$$

Once again, we choose initial data compatible with the boundary condition, for instance

$$V_p|_{z=0} = -v_0(x, 0)e^{-Z}. \tag{3.8}$$

Then as was the case for $U_p$, there exists a unique solution $V_p$ of (3.7) and (3.8) satisfying the Duhamel principle:

$$V_p(t, x, Z) = -v_0(x, 0)e^{-Z} - v_0(x, 0) \int_0^t \int_0^{\infty} G(t-s, Z; Z') e^{-Z'} dZ' ds,$$

where $G(t-s, Z; Z')$ is the heat kernel defined as in (3.5). It is clear from this integral representation for $V_p$ that the only dependence on $x$ is due to $v_0(x, 0)$. Thus, we easily obtain the following lemma.

**Lemma 3.2.** There exists a unique solution $V_p$ to the problem (3.7) and (3.8) on $[0, T] \times \mathbb{R}_+ \times \mathbb{R}_+$, for any $T > 0$. Furthermore, for any $p > 1$, there is some positive constant $C_0$ that depends on $p$ and $T$ such that

$$\| \partial_t^k V_p \|_{L^\infty(0,T; W^{0,p}(\mathbb{R}_+))} \leq C_0\| \partial_t^k v_0(\cdot, 0) \|_{L^p(\mathbb{R}_+)} , \quad k = 0, 1, 2, \tag{3.9}$$

and the jump of discontinuity $[V_p]|_{z=0}$ satisfies

$$\|[V_p]|_{z=0}\|_{L^\infty(0,T; W^{1,p}(\mathbb{R}_+))} \leq C_0|v_0(x, 0)|. \tag{3.10}$$

**Proof.** Similarly as for $U_p$, the integral representation for $V_p$ easily yields

$$\| \partial_t^k V_p(x) \|_{L^\infty(0,T; W^{0,p}(\mathbb{R}_+))} \leq C_0\| \partial_t^k v_0(x, 0) \|, \quad k = 0, 1, 2, \tag{3.11}$$

for each nonzero $x \in \mathbb{R}$. Taking the $L^p$ norm of this inequality in $x$ gives (3.9) at once. The estimate for the jump of discontinuity of $V_p$ follows similarly by noting that the jump $[V_p]|_{z=0}$ satisfies the similar integral representation to that of $V_p$. \qed
3.1.3. Construction of $V_{KH}$. Similarly, plugging the ansatz (3.1) into the system (2.1) yields the profile equation for $V_{KH}$:
\[
\partial_t V_{KH} = (1 + |\partial s|^2) \partial^2_X V_{KH}, \quad [V_{KH}]_{x=0} = -[v_0]_{x=0}, \quad [\partial_X V_{KH}]_{x=0} = 0.
\]  
We choose the initial data:
\[
V_{KH}|_{t=0}(X, z) = \mp \frac{[v_0]_{x=0}}{2} e^{\mp X}, \quad \pm X > 0.
\]  
We will derive necessary estimates for the profile $V_{KH}$. It turns out to be convenient to introduce a change of variables:
\[
\tilde{X} = X, \quad \tilde{t} = \int_0^t (1 + |\partial s|^2(s, z)) ds,
\]  
and write
\[
V_{KH}(t, X, z) = \tilde{V}_{KH}(\tilde{t}, X, z), \quad \tilde{X}(t, X, z).
\]  
In these new variables, we then have
\[
\partial_{\tilde{t}} \tilde{V}_{KH} = \partial_X^2 \tilde{V}_{KH}, \quad [\tilde{V}_{KH}]_{x=0} = -[v_0]_{x=0}, \quad [\partial_X \tilde{V}_{KH}]_{x=0} = 0,
\]  
with initial data
\[
\tilde{V}_{KH}|_{\tilde{t}=0} = \mp \frac{[v_0]_{x=0}}{2} e^{\mp \tilde{X}}, \quad \pm \tilde{X} > 0.
\]  
The systems (3.14) and (3.15) are the heat equations on each half lines $\tilde{X} < 0$ and $\tilde{X} > 0$, with $z$ being a parameter. Thus, the Duhamel principle for the heat equation yields a candidate for $\tilde{V}_{KH}(\tilde{t}, \tilde{X}, z)$ as
\[
\tilde{V}_{KH}(\tilde{t}, \tilde{X}, z) = -\frac{[v_0]_{x=0}}{2} e^{-\tilde{X}} - \frac{[v_0]_{x=0}}{2} \int_0^{\tilde{t}} \int_0^{\infty} G(\tilde{t} - \tilde{s}, \tilde{X}; \tilde{X}') e^{-\tilde{X}'} d\tilde{X}' d\tilde{s},
\]  
for $\tilde{X} > 0$, and
\[
\tilde{V}_{KH}(\tilde{t}, \tilde{X}, z) = \frac{[v_0]_{x=0}}{2} e^{\tilde{X}} + \frac{[v_0]_{x=0}}{2} \int_0^{\tilde{t}} \int_{-\infty}^{0} G(\tilde{t} - \tilde{s}, \tilde{X}; \tilde{X}') e^{\tilde{X}'} d\tilde{X}' d\tilde{s},
\]  
with the Green function for the heat equation defined by
\[
G(\tilde{t}, X; X') = G(t, X - X') - G(t, X + X'), \quad G(t, X) = \frac{1}{\sqrt{4\pi t}} e^{-X^2/4t}.
\]  
It is straightforward to check that these definitions of $\tilde{V}_{KH}$ on $\mathbb{R}_+ \times \mathbb{R}_+$ indeed satisfy the boundary and jump conditions from (3.14) and (3.15).

Furthermore, similarly to those estimates obtained for $U_p$ and $V_p$, we can easily obtain
\[
\|\partial_z^k \tilde{V}_{KH}(z)\|_{L^\infty([0, T]; W^{1,r}(\mathbb{R}_+))} \leq C_0 \|\partial_z^k v_0(x, z)\|_{L^1(\mathbb{R}_+)}, \quad k = 0, 1, 2,
\]  
for each $z \in \mathbb{R}_+$ and for some positive constant $C_0$ that depends only on $p$ and $T$. Going back to the original coordinates $(t, X)$, we have thus shown
\[
\|\partial_z^k V_{KH}(z)\|_{L^\infty([0, T]; W^{1,r}(\mathbb{R}_+))} \leq C_0 \|\partial_z^k v_0(x, z)\|_{L^1(\mathbb{R}_+)},
\]  
for $k = 0, 1, 2$ and for each $z \in \mathbb{R}_+$.

Collecting this information, we obtain the following lemma.

**Lemma 3.3.** There exists a unique solution $V_{KH}$ to the problem (3.12) and (3.13) on $[0, T] \times \mathbb{R}_+ \times \mathbb{R}_+$, for any $T > 0$. Furthermore, for any $p > 1$, there is some positive constant $C_0$ that depends on $p$ and $T$ such that
\[
\|\partial_z^k V_{KH}\|_{L^\infty([0, T]; L^p(\mathbb{R}_+; W^{1,r}(\mathbb{R}_+)))} \leq C_0 \|\partial_z^k v_0(x, z)\|_{L^1(\mathbb{R}_+)},
\]  
for $k = 0, 1, 2$. 

**Proof.** The estimate (3.17) is obtained easily by taking to both sides of (3.16) the usual $L^p$ norm in $z$ and using the triangle inequality.

3.1.4. Construction of $V_b$. Finally, in the ‘box’ where the interactions take place, we obtain from the equation for $v^\epsilon$ with the Ansatz (3.1) the following equation for the interaction profile $V_b(t,X,Z)$:

$$\frac{\partial}{\partial t}V_b = \Delta_{XZ} V_b,$$

where $\Delta_{XZ} = \partial^2_X + (\partial_Z - \partial_z\psi_{\epsilon=0}\partial_X)^2$, (3.18)

with the boundary and jump conditions:

$$V_{b|t=0} = -V_K\psi_{\epsilon=0}, \quad [V_b]_{t=0} = [V_P]_{t=0}, \quad [\partial_X V_b]_{t=0} = 0,$$

and $V_b \to 0$ as $X \to \pm\infty$ or $Z \to \pm\infty$. Next, we choose the initial data for $V_b$:

$$V_{b|t=0} = \begin{cases} -\frac{1}{2}e^{-|X|}[V_P]_{t=0}, & X > 0 \\ \frac{1}{2}e^{-|X|}[V_P]_{t=0}, & X < 0. \end{cases}$$

(3.19)

which satisfy all the conditions in (3.19), thanks to (3.8) and to (3.13).

We observe at once that these boundary and jump conditions in (3.2), (3.7), (3.12) and (3.19) make the ansatz $v_\text{app}^\epsilon$ defined as in (3.1) smooth out the inviscid solution $v^\epsilon$ (at least with $C^1$ regularity) as well as satisfy the correct no-slip boundary conditions (1.6) for the depleted Navier–Stokes system. We will see in the next section that these ansatz $v_\text{app}^\epsilon$ indeed provide a good approximation for $v^\epsilon$, and are sufficient to show the desired convergence.

We will show in this section that the profile $V_b$ exists and we then derive necessary estimates to carry out the convergence stated in the main theorem 1.1. In fact, we could continue our study by employing the Green function of the heat equation on the half-space as done previously on the half-line. However, we choose to proceed with the analysis by energy estimates, as it appears natural for the proof of our desired convergence.

To begin, it appears convenient to introduce $\tilde{w}$ through

$$V_b = \begin{cases} \tilde{w} - \frac{1}{2}[V_P]_{t=0}e^{-|X|}, & X > 0 \\ \tilde{w} + \frac{1}{2}[V_P]_{t=0}e^{-|X|}, & X < 0. \end{cases}$$

The function $\tilde{w}$ then solves

$$\frac{\partial}{\partial t}\tilde{w} = \Delta_{XZ}\tilde{w} + J_\epsilon \epsilon e^{-|X|}, \quad X > 0,$$

$$\frac{\partial}{\partial t}\tilde{w} = \Delta_{XZ}\tilde{w} + J_\epsilon \epsilon e^{-|X|}, \quad X < 0,$$

(3.21)

with the boundary and jump conditions:

$$[\tilde{w}]_{t=0} = 0, \quad [\partial_X \tilde{w}]_{t=0} = 0, \quad \lim_{|X|\to\infty} \tilde{w} = \lim_{Z\to\infty} \tilde{w} = 0,$$

(3.22)

and

$$\tilde{w}_{t=0} = -V_K\psi_{\epsilon=0} \frac{1}{2}e^{-|X|}[v_\text{app}]_{t=0}, \quad X > 0$$

$$\tilde{w}_{t=0} = -V_K\psi_{\epsilon=0} \frac{1}{2}e^{-|X|}[v_\text{app}]_{t=0}, \quad X < 0.$$  

(3.23)

Moreover $\tilde{w}$ vanishes at the initial time:

$$\tilde{w}_{t=0} = 0.$$  

(3.24)

Here, $J_{\pm}$ in (3.21) collects the terms involving the jumps of discontinuity. Direct calculation together with a use of (3.7) gives

$$J_+ = \frac{1}{2} \left((1 + |\partial_z\psi_{\epsilon=0}|^2)[V_P]_{t=0} + 2\partial_z\psi_{\epsilon=0}[\partial_Z V_P]_{t=0}\right),$$

$$J_- = \frac{1}{2} \left((1 + |\partial_z\psi_{\epsilon=0}|^2)[V_P]_{t=0} - 2\partial_z\psi_{\epsilon=0}[\partial_Z V_P]_{t=0}\right).$$  

(3.25)
By applying the estimate (3.10) obtained in lemma 3.2, we then have
\[
\int_0^T \| J_\pm(t) \|_{L_w^p}^p \, dt \leq C_0 |v_0(x, 0)|_{L_w^p},
\] (3.26)
for some \( C_0 \) that depends on \( p \) and \( T \).

We are able to provide the following estimates.

**Lemma 3.4.** There exists a unique solution \( \tilde{w} \) to the problem (3.21)-(3.23) on \([0, T] \times \mathbb{R}_+ \times \mathbb{R}_+\), for any \( T > 0 \). Furthermore, for any \( p > 1 \), there is some positive constant \( C_0 \) that depends on \( p \) and \( T \) such that there holds
\[
\frac{d}{dt} \| \tilde{w} \|_{L_w^p}^p + \int_{\mathbb{R}^2} |\tilde{w}|^{p-2} |\nabla_{XZ} \tilde{w}|^2 \, dX \, dZ + \int_{\mathbb{R}^2} |\partial_Z \tilde{w}|^{p-2} |\nabla_{XZ} \partial_Z \tilde{w}|^2 \, dX \, dZ \leq C_0 \left( 1 + \| J_\pm \|_{W^1_p} + \| \tilde{w} \|_{L_w^p}^p \right)
\] (3.27)

Here, \( \nabla_{XZ} \psi := (\partial_X, \partial_Z - \partial_z \psi_{\parallel,0}, \partial_x) \).

**Proof.** By multiplying by \( |\tilde{w}|^{p-2} \tilde{w} \) to equation (3.21) and integrating it over \( \mathbb{R}^2 \), one has
\[
\frac{1}{p} \frac{d}{dt} \| \tilde{w} \|_{L_w^p}^p = \int_{\mathbb{R}^2} \left( \Delta_{XZ} \tilde{w} + J_\pm e^{\mp X} \right) |\tilde{w}|^{p-2} \tilde{w} \, dX \, dZ.
\]

For the term involving \( J_\pm \), the standard Hölder’s inequality gives
\[
\int_{\mathbb{R}^2} e^{\mp X} J_\pm |\tilde{w}|^{p-1} \, dX \, dZ \lesssim \| \tilde{w} \|_{L_w^p}^{p-1} \| J_\pm \|_{L_w^p}.
\]

Here and in what follows, by \( f \lesssim g \) we always mean that \( f \leq C_0 g \), for some positive constant \( C_0 \) that only depends on \( p \) and \( T \). Now, integration by parts yields
\[
\int_{\mathbb{R}^2} \Delta_{XZ} \tilde{w} |\tilde{w}|^{p-1} \tilde{w} \, dX \, dZ = - (p - 1) \int_{\mathbb{R}^2} |\tilde{w}|^{p-2} |\nabla_{XZ} \tilde{w}|^2 \, dX \, dZ - \int_{\mathbb{R}} (\partial_Z - \partial_z \psi_{\parallel,0} \partial_x) \tilde{w} |\tilde{w}|^{p-2} \tilde{w} |_{z=0} \, dX
\]
\[
- \int_{\mathbb{R}} \left( \partial_X \tilde{w} |\tilde{w}|^{p-2} \tilde{w} - \partial_z \psi_{\parallel,0} \partial_x \tilde{w} |\tilde{w}|^{p-2} \tilde{w} |_{z=0} \right) \, dZ.
\]

in which the last term on the right-hand side vanishes due to the jump conditions (3.22) on \( \tilde{w} \) and on \( \partial_x \tilde{w} \). Thus, we obtain
\[
\int_{\mathbb{R}^2} \Delta_{XZ} \tilde{w} |\tilde{w}|^{p-1} \tilde{w} \, dX \, dZ = - (p - 1) \int_{\mathbb{R}^2} |\tilde{w}|^{p-2} |\nabla_{XZ} \tilde{w}|^2 \, dX \, dZ - \int_{\mathbb{R}} \partial_Z \tilde{w} |\tilde{w}|^{p-2} \tilde{w} |_{z=0} \, dX.
\]

In summary, we have shown
\[
\frac{d}{dt} \| \tilde{w} \|_{L_w^p}^p + p(p - 1) \int_{\mathbb{R}^2} |\tilde{w}|^{p-2} |\nabla_{XZ} \tilde{w}|^2 \, dX \, dZ \lesssim \| \tilde{w} \|_{L_w^p}^{p-1} \| J_\pm \|_{L_w^p} + \int_{\mathbb{R}} \partial_Z \tilde{w} |\tilde{w}|^{p-2} \tilde{w} |_{z=0} \, dX.
\] (3.28)

For the boundary term, the Young’s inequality yields
\[
\int_{\mathbb{R}} |\partial_Z \tilde{w} |\tilde{w}|^{p-2} \tilde{w} |_{z=0} | \, dX \lesssim \| \tilde{w} |_{z=0} \|_{L_w^p}^p + \| \partial_Z \tilde{w} |_{z=0} \|_{L_w^p}^p.
\]
The first boundary term can be easily treated by the trace inequality. We treat the second boundary term by the $H^2$ energy estimate. To this end, we take $Z$-derivative of equation (3.21) and multiply by $|\partial_Z \tilde{w}|^{p-2} \partial_Z \tilde{w}$ to the resulting equation. We simply get

$$\int_{\mathbb{R}_{+}^2} \frac{d}{dt} \|\partial_Z \tilde{w}\|_{L^p_{xz}}^p = \int_{\mathbb{R}_{+}^2} \left( \Delta_{x,x}^{xy} \partial_Z \tilde{w} + \partial_Z J_{\pm} e^{\mp X} \right) |\partial_Z \tilde{w}|^{p-2} \partial_Z \tilde{w} \, dx \, dz.$$

Again, by applying Hölder’s inequality to the last term on the right-hand side, we have

$$\int_{\mathbb{R}_{+}^2} \partial_Z J_{\pm} e^{\mp X} |\partial_Z \tilde{w}|^{p-2} \partial_Z \tilde{w} \, dx \, dz \lesssim \|\partial_Z J_{\pm}\|_{L^p_x} \|\partial_Z \tilde{w}\|_{L^{p-1}_{xz}}^{p-1}.$$

Next, the integration by parts yields

$$\int_{\mathbb{R}_{+}^2} \Delta_{x,x}^{xy} |\partial_Z \tilde{w}|^{p-2} \partial_Z \tilde{w} \partial_Z \tilde{w} \, dx \, dz = -(p-1) \int_{\mathbb{R}_{+}^2} |\partial_Z \tilde{w}|^{p-2} \left| \nabla_{x,x}^{xy} \partial_Z \tilde{w} \right|^2 \, dx \, dz$$

$$- \int_{\mathbb{R}} \left( \partial_Z - \partial_x \psi_{\parallel,0} \partial_x \right) \partial_Z \tilde{w} |\partial_Z \tilde{w}|^{p-2} \partial_Z \tilde{w}_{|z=0} \, dx$$

$$- \int_{\mathbb{R}} \left( \partial_Z \tilde{w} - \partial_z \psi_{\parallel,0} \partial_z \right) \partial_Z \tilde{w} |\partial_Z \tilde{w}|^{p-2} \partial_Z \tilde{w}_{|z=0} \, dx \partial_Z \tilde{w} |\partial_Z \tilde{w}|^{p-2} \partial_Z \tilde{w} \, dx \, dz$$

in which again the last term on the right-hand side vanishes due to the jump condition (3.22). By using the equation for $\tilde{w}$, we can write the boundary term as

$$- \int_{\mathbb{R}} \left( \partial_Z - \partial_x \psi_{\parallel,0} \partial_x \right) \partial_Z \tilde{w} |\partial_Z \tilde{w}|^{p-2} \partial_Z \tilde{w}_{|z=0} \, dx$$

$$= - \int_{\mathbb{R}} \left( \partial_Z - \partial_x \psi_{\parallel,0} \partial_x \right) \partial_Z \tilde{w} - \partial_x \psi_{\parallel,0} \partial_x \partial_Z \tilde{w} |\partial_Z \tilde{w}|^{p-2} \partial_Z \tilde{w}_{|z=0} \, dx$$

$$- \int_{\mathbb{R}} \left( \partial_Z - \partial_x \psi_{\parallel,0} \partial_x \right) \partial_Z \tilde{w} - \partial_x \psi_{\parallel,0} \partial_x \partial_Z \tilde{w} |\partial_Z \tilde{w}|^{p-2} \partial_Z \tilde{w}_{|z=0} \, dx \partial_Z \tilde{w} |\partial_Z \tilde{w}|^{p-2} \partial_Z \tilde{w} \, dx \, dz$$

in which the integral term involving $\partial_Z \tilde{w} |\partial_Z \tilde{w}|^{p-2} \partial_Z \tilde{w}_{|z=0}$ vanishes due to the jump condition (3.22) and the fact that it is a perfect derivative in $X$. For the other terms, we note that at $Z = 0$ we have

$$\partial_z \tilde{w} - (1 + |\partial_x \psi_{\parallel,0}|^2) \partial_x \tilde{w} - J_{\pm} e^{\mp X} = \partial_z V_{KH} - (1 + |\partial_x \psi_{\parallel,0}|^2) \partial_x V_{K} + c_{\pm} e^{\mp X}$$

$$= c_{\pm} e^{\mp X}.$$

for some constant $c_{\pm}$; here, the last identity was due to a use of the equation for $V_{K}$. Thus, using this and the Sobolev embedding, we have

$$- \int_{\mathbb{R}} \left( \partial_Z - \partial_x \psi_{\parallel,0} \partial_x \right) \partial_Z \tilde{w} |\partial_Z \tilde{w}|^{p-2} \partial_Z \tilde{w}_{|z=0} \, dx$$

$$\lesssim \|\partial_Z \tilde{w}_{|z=0}\|_{L^p_x}$$

$$\lesssim \|\partial_Z \tilde{w}\|_{L^p_{xz}} + \left( \int_{\mathbb{R}_{+}^2} |\partial_Z \tilde{w}|^{p-2} |\partial_Z \tilde{w}|^2 \, dz \, dx \right)^{1/p}.$$

Thus, applying Young’s inequality to the last term and combing all the above estimates, we obtain

$$\frac{d}{dt} \|\partial_Z \tilde{w}\|_{L^p_{xz}}^p + \int_{\mathbb{R}_{+}^2} |\partial_Z \tilde{w}|^{p-2} |\nabla_{x,x}^{xy} \partial_Z \tilde{w} |^2 \, dx \, dz \lesssim 1 + \|\partial_Z \tilde{w}\|_{L^p_{xz}} + \|\partial_Z J_{\pm}\|_{L^p_x} \|\partial_Z \tilde{w}\|_{L^{p-1}_{xz}}^{p-1}.$$

This together with the $L^2$ estimate (3.28) yields the lemma at once. \hfill \Box
Lemma 3.5. For any solutions $\tilde{w}$ to (3.21)–(3.23), there holds
\[
\frac{d}{dt}\|\partial X \tilde{w}\|_{L^p_t L^2_x}^p + \int_{\mathbb{R}^2_x} |\partial_X |\tilde{w}|^{p-2}|\nabla_{\!x}^{\frac{p}{2}} \partial_X \tilde{w}|^2 \, dX \, dZ + \int_{\mathbb{R}^2_x} |\partial_{XX} \tilde{w}|^{p-2}|\nabla_{\!x}^{\frac{p}{2}} \partial_{XX} \tilde{w}|^2 \, dX \, dZ \\
\lesssim 1 + \|J_\pm\|_{W^{1,p}_x}^p + \|\tilde{w}\|_{W^{1,p}_x}^p.
\]

Proof. The proof of this lemma follows word for word that of lemma 3.4, upon noting that the jump of discontinuity of $\partial_{XX} \tilde{w}$ across $\{X = 0\}$ can be computed through equation (3.21) for $\tilde{w}$ to give $[\partial_{XX} \tilde{w}]|_{x=\pm} = J_\pm - J_\mp$. Note also that we may need to apply Sobolev embedding:
\[
\|\partial_{XX} \tilde{w}|_{L^2_x}\leq \|\tilde{w}\|_{L^p_x} + \left(\int_{\mathbb{R}^2_x} |\partial_{XX} \tilde{w}|^{p-2}|\nabla_{\!x}^{\frac{p}{2}} \partial_{XX} \tilde{w}|^2 \, dX \, dZ \right)^{1/p}.
\]

We thus omit the further detail of the proof of the lemma. \hfill \square

To conclude this subsection, we summarize our estimate for $V_b$ in the following lemma.

Lemma 3.6. There exists a unique solution $V_b$ of the problem (3.18) with the boundary and jump conditions (3.19) and initial data (3.20). Furthermore, for any $p > 1$, there exists some positive constant $C_0$ that depends on $p$ and $T$ such that there holds
\[
\sup_{0 \leq t \leq T} \|V_b(t)\|_{W^{1,p}_x} + \int_0^T \int_{\mathbb{R}^2_x} |\partial_X V_b|^{p} \, dX \, dZ \, dt \\
\leq C_0 \left(\|v_0(0, \cdot)\|_{\mathbb{R}^2_x} + \|v_0(\cdot, 0)\|_{\mathbb{R}^2_x} + \|v_0(\cdot, 0)\|_{W^{1,p}(\mathbb{R}^2_x)}\right).
\]

Proof. This is a collection of estimates from lemmas 3.4 and 3.5, the estimate (3.26) on $J_{\pm}$, the jump estimate (3.10) from lemma 3.2 and a use of the standard Gronwall inequality. Indeed, Lemmas 3.4 and 3.5 in particular yields
\[
\sup_{0 \leq t \leq T} \|\tilde{w}\|_{W^{1,p}_x} + \int_0^T \int_{\mathbb{R}^2_x} |\partial_X \tilde{w}|^{p-2}|\nabla_{\!x}^{\frac{p}{2}} \partial_X \tilde{w}|^2 \, dX \, dZ \, dt
\]
is bounded. This together with the standard Young’s inequality yields that
\[
\int_0^T \int_{\mathbb{R}^2_x} |\partial_X \tilde{w}|^{p} \, dX \, dZ \, dt = \int_0^T \int_{\mathbb{R}^2_x} \left|\partial_X \tilde{w}\right|^{p} |\partial_X \tilde{w}|^{\frac{p}{2}} |\nabla_{\!x}^{\frac{p}{2}} \partial_X \tilde{w}|^{\frac{p}{4}} \, dX \, dZ \, dt \\
\leq \int_0^T \int_{\mathbb{R}^2_x} |\partial_X \tilde{w}|^{p} \, dX \, dZ \, dt + \int_0^T \int_{\mathbb{R}^2_x} |\partial_X \tilde{w}|^{p-2} |\nabla_{\!x}^{\frac{p}{2}} \partial_X \tilde{w}|^2 \, dX \, dZ \, dt
\]
is also bounded. The lemma is proved. \hfill \square

3.2. Remainders

We observe that, with the above profiles, the functions $(u_{app}^\epsilon, v_{app}^\epsilon)$ given by the formula (3.1) satisfy
\[
\begin{align*}
\partial_t u_{app}^\epsilon &= \epsilon \partial_{XX} u_{app}^\epsilon + E_u, \\
\partial_t v_{app}^\epsilon + (u_{app}^\epsilon - u_0)\partial_x v_{app}^\epsilon &= \epsilon \Delta_{xz} v_{app}^\epsilon + E_v, \\
\langle u_{app}^\epsilon, v_{app}^\epsilon \rangle|_{x=\pm} &= 0, \\
\langle v_{app}^\epsilon |_{x=0} &= 0, \\
\partial_x v_{app}^\epsilon |_{x=0} &= 0. 
\end{align*}
\]
where direct computations give

$$E^u = \epsilon \partial_z^2 u_0,$$

and

$$E^v = \epsilon \Delta_{\epsilon Z}^\psi v_0 + (\Delta_{\epsilon Z}^\psi - \Delta_{\epsilon Z}^\phi) V_b - 2 \sqrt{\epsilon} \partial_z \psi \partial_z^2 V_KH - \sqrt{\epsilon} \partial_z^2 \psi \partial_x V_KH + \epsilon \partial_z^2 V_KH$$

$$+ \epsilon (1 + |\partial_z \psi|^2) \partial_z^2 V_p - 2 \sqrt{\epsilon} \partial_z \psi \partial_z^2 V_p - \epsilon \partial_z^2 \psi \partial_z V_p - U_p \partial_z v_{app}.$$  

**Remark 3.7.** We note that $E^v$ contains a singular term: $\frac{1}{\sqrt{\epsilon}} U_p(t, z/\sqrt{\epsilon}) \partial_z V_KH(t, x/\sqrt{\epsilon}, z)$ in $U_p \partial_z v_{app}$. This singular term is *a priori* not better than bounded in $L^2$ and thus we cannot obtain the convergence in the $L^2$ space this way. However, its $L^p$ norm has an order of $\epsilon^{1/p-1/2}$, which tends to zero in $L^p$, for $1 < p < 2$, as $\epsilon \to 0$.

**Proposition 3.8.** For all $p > 1$, there hold uniform estimates:

$$\|E^u(t)\|_{L^2} \leq \epsilon \|\partial_z^2 u_0\|_{L^2}, \quad \int_0^T \|E^v(t)\|_{L^p}^p \, dt \leq C_{in}(p, T) \epsilon^{1-p/2}, \quad (3.31)$$

for some positive constant $C_{in}(p, T)$ that depends continuously on the initial data, the discontinuous jump of the Euler flow $v_0$, the number $p > 1$, and the time $T$. More precisely, the constant $C_{in}(p, T)$ is bounded by

$$C_0 \left( \|v_0(x, 0)\|_{L^2} + \|v_0(x, \cdot)\|_{W^{1,p}(\mathbb{R}_z)} + \|v_0(\cdot, 0)\|_{W^{1,p}(\mathbb{R}_x)} + \|\Delta v_0\|_{L^p_{xz}(\mathbb{R}_x \times \mathbb{R}_z)} \right)$$

for some $C_0$ that depends only on $T$ and $p$.

We now give a proof of proposition 3.8. The first estimate is clear from the definition $E^u = \epsilon \partial_z^2 u_0$. We prove the second estimate. We will use the following simple lemma.

**Lemma 3.9.** For any reasonable function $u = u(z)$, there holds

$$\|u(z/\sqrt{\epsilon})\|_{L^2_z(\mathbb{R}_z)} \lesssim \epsilon^{1/2} \|u(Z)\|_{L^2_z(\mathbb{R}_z)}.$$

**Proof.** It is clear from the changing of the variable from $z$ to $z/\sqrt{\epsilon}$. □

We now check term by term in $E^v$. The term $\epsilon \Delta_{\epsilon Z}^\psi v_0$ is clear, giving the contribution of $\epsilon \|\Delta v_0\|_{L^p_{xz}(\mathbb{R}_x \times \mathbb{R}_z)}$. Next, note that

$$\Delta_{\epsilon Z}^\phi - \Delta_{\epsilon Z}^\psi = (|\partial_z \psi|^2 - |\partial_z \psi_{l=\cdot}|^2) \partial_z^2 Z - 2 (\partial_z \psi - \partial_z \psi_{l=\cdot}) \partial_z^2 X - \partial_z^2 \psi \partial_x X.$$  

Thus, the estimate (3.29) for $v_b$ specifically gives us the desired $L^p$ estimate for $(\Delta_{\epsilon Z}^\psi - \Delta_{\epsilon Z}^\phi) v_0$, after a change of variables $(x, z)$ to $(X, Z)$ with $X = x/\sqrt{\epsilon}$, $Z = z/\sqrt{\epsilon}$, yielding a small factor of $\epsilon$. Similarly, for all the terms:

$$-2 \sqrt{\epsilon} \partial_z \psi \partial_z^2 V_KH - \sqrt{\epsilon} \partial_z^2 \psi \partial_x V_KH + \epsilon \partial_z^2 V_KH + \epsilon (1 + |\partial_z \psi|^2) \partial_z^2 V_p$$

$$-2 \sqrt{\epsilon} \partial_z \psi \partial_z^2 Z V_p - \epsilon \partial_z^2 \psi \partial_z V_p$$

the estimates from lemmas 3.1, 3.2, and 3.3 immediately yield that the $L^p$ norm of these are bounded by

$$C_0 \epsilon^{1/2} \left( \|v_0(x, 0)\|_{L^2} + \|v_0(x, \cdot)\|_{W^{1,p}(\mathbb{R}_z)} + \|v_0(\cdot, 0)\|_{W^{1,p}(\mathbb{R}_x)} \right).$$

Finally, let us treat the term $U_p \partial_z v_{app}$. From the definition of $v_{app}$, the singular terms in $U_p \partial_z v_{app}$ are

$$\frac{1}{\sqrt{\epsilon}} U_p(t, Z) \partial_X V_KH(t, X, Z) + \frac{1}{\sqrt{\epsilon}} U_p(t, Z) \partial_Z V_b(t, X, Z).$$
We then use Lemma 3.9 to treat these singular terms. For example, we compute
\[
\epsilon^{-p/2} \int_{\mathbb{R}^2} |U_p(t, Z) \partial_X V_b(t, X, Z)|^p \, dx \, dZ \lesssim \epsilon^{1-p/2} \int_{\mathbb{R}^2} |U_p(t, Z)\partial_X V_b(t, X, Z)|^p \, dX \, dZ
\]
\[
\lesssim \epsilon^{1-p/2} \|U_p\|_{L^p_X}^p \|\partial_X V_b\|_{L^p_{XZ}}^p \lesssim \epsilon^{1-p/2}.
\]

The other terms are entirely similar. This completes the proof of the estimate (3.31), and thus the proposition 3.8.

3.3. Convergence

We are ready to prove the convergence stated in the main theorem.

Now we consider the solutions $R_\nu, R^\nu$ of the following problem:

\[
\begin{align*}
\partial_t R_\nu &= \epsilon \partial^2_z R_\nu + E_\nu, \\
\partial_t R^\nu + (U_\nu + R^\nu) \partial_t R^\nu &= \epsilon \Delta^\nu_{xz} R^\nu - R_\nu \partial_\nu v^\epsilon_{\text{app}} + E^\nu \\
(R_\nu, R^\nu)|_{t=0} &= 0, \\
\lim_{z \to +\infty} (R_\nu, R^\nu) &= 0, \\
[R^\nu]|_{x=0} &= 0, \\
\partial_x R^\nu|_{x=0} &= 0.
\end{align*}
\]

(3.32)

Then the functions $(u^\epsilon, v^\epsilon)$ defined by
\[
\begin{align*}
u(t, z) &= u^\epsilon_{\text{app}}(t, z) + R_\nu(t, z) \\
v^\epsilon(t, x, z) &= v^\epsilon_{\text{app}}(t, x, z) + R^\nu(t, x, z),
\end{align*}
\]
satisfy equations (2.1) and (2.2)–(2.4).

The well-posedness of the problem (3.32) follows at once from the following a priori estimates:

**Lemma 3.10.** There hold
\[
\begin{align*}
d \|R_\nu\|_{L^2_t}^2 + \epsilon \|\partial_\nu R_\nu\|_{L^2_t}^2 &\lesssim \|R_\nu\|_{L^p_t} \|E_\nu\|_{L^1_t}, \\
\frac{1}{p} \frac{d}{dt} \|R^\nu\|_{L^p_t}^p + \epsilon \int_{\mathbb{R}^2} |R^\nu|^{p-2} |\nabla^\nu_{xz} R^\nu|^2 \, dx \, dz &\lesssim \left( \|R_\nu \partial_\nu v^\epsilon_{\text{app}}\|_{L^1_t} + \|E_\nu\|_{L^1_t} \right) \|R^\nu\|_{L^p_{xz}}^{p-1}.
\end{align*}
\]

where $\nabla^\nu_{xz} := (\partial_x, \partial_z - \partial_x \psi \partial_x)$.

**Proof.** Multiply by $R_\nu$ and $|R^\nu|^{p-2} R^\nu$ the respective equations in (3.32) and integrate the resulting equations over $\mathbb{R}^+ \times \mathbb{R}^2$. The claimed estimate for $R_\nu$ is straightforward. For the $R^\nu$ estimate, we have
\[
\frac{1}{p} \frac{d}{dt} \int_{\mathbb{R}^2} |R^\nu|^p \, dx + \frac{1}{p} \int_{\mathbb{R}^2} (U_\nu + R^\nu)|R^\nu|^{p-2} \partial_\nu R^\nu R^\nu \, dx \, dz
\]
\[
= \int_{\mathbb{R}^2} \left( \epsilon |\Delta^\nu_{xz} R^\nu - R_\nu \partial_\nu v^\epsilon_{\text{app}} - E^\nu| \right) |R^\nu|^{p-2} R^\nu \, dx \, dz.
\]
We first note that integration by parts yields
\[
\int_{\mathbb{R}^2} (U_\nu + R^\nu)|R^\nu|^{p-2} \partial_\nu R^\nu R^\nu \, dx \, dz = \int_{\mathbb{R}^2} (U_\nu + R^\nu) \partial_\nu \left( \frac{|R^\nu|^p}{p} \right) \, dx \, dz = 0
\]
Boundary-layer interactions in the plane-parallel incompressible flows

\[ \epsilon \int_{\mathbb{R}^2_+} \Delta^\psi R^\psi |R^\psi|^{p-2} R^\psi \, dx \, dz = - \epsilon \int_{\mathbb{R}^2_+} |R^\psi|^{p-2} |\nabla_{x,z} R^\psi|^2 \, dx \, dz, \]

upon noting that there is no contribution on the boundary and the interface due to the vanishing boundary and jump conditions for R^\psi. Finally, the standard Hölder inequality yields

\[ \int_{\mathbb{R}^2_+} (|R^\psi \partial_x v_{app}| + |E^\psi|) |R^\psi|^{p-1} \, dx \, dz \lesssim \left( \|R^\psi \partial_x v_{app}\|_{L^p_{x,t}} + \|E^\psi\|_{L^p_{x,z}} \right) \|R^\psi\|_{L^p_{x,t}}^{p-1}. \]

Collecting these estimates together proves the lemma. \( \square \)

It is straightforward to verify that

\[ (u_{app}(t,z), v_{app}(t,x,z)) \to v^0 \text{ in } L^\infty(0,T; L^2(\mathbb{R}_+ \times L^p(\mathbb{R} \times \mathbb{R}_+))), \]

as \( \epsilon \to 0 \), upon using the estimates on the profiles from lemmas 3.1, 3.2, 3.3, and 3.6, and the lemma 3.9. Therefore in order to prove theorem 1.1, it remains to prove that

\[ (R^u(t,z), R^v(t,x,z)) \to 0 \text{ in } L^\infty(0,T; L^2(\mathbb{R}_+ \times L^p(\mathbb{R} \times \mathbb{R}_+))), \quad (3.33) \]

as \( \epsilon \to 0 \).

From lemma 3.10 and proposition 3.8, by the standard ODE estimate and the Gronwall inequality, we immediately obtain the uniform bounds

\[ \|R^u\|_{L^\infty_t L^2_x} + \epsilon^{1/2} \|\partial_t R^u\|_{L^2_x} \lesssim \epsilon, \]

with noting that \( \|E^u\|_{L^2_x} \lesssim \epsilon \) and \( R^u_{\text{sum}} = 0 \). In addition, this estimate yields

\[ \int_0^T \|R^u(t,\cdot)\|_{L^2_x} \, dt \lesssim \|R^u\|_{L^2_x}^2 \|\partial_t R^u\|_{L^2_x}^2 \lesssim \epsilon^3. \]

This together with the bound \( \|\partial_x v_{app}\|_{L^\infty_t L^p_{x,z}} \lesssim 1 \), which again follows from the estimates on the profiles, yields

\[ \int_0^T \|\partial_x v_{app}\|_{L^p_{x,z}}^p \, dt \lesssim \|\partial_x v_{app}\|_{L^p_{x,z}}^p \int_0^T \|R^u\|_{L^p_x}^p \, dt \lesssim \epsilon^{3p/4}. \]

In addition, the second estimate from lemma 3.10 implies

\[ \frac{d}{dt} \|R^u\|_{L^p_x}^p \lesssim \|R^u\|_{L^p_x}^p + \left( \|R^u \partial_x v_{app}\|_{L^p_{x,z}}^p + \|E^u\|_{L^p_{x,z}}^p \right), \]

which gives

\[ \|R^u(t)\|_{L^p_x}^p \lesssim \int_0^t \|R^u(s)\|_{L^p_x}^p \, ds + \left( \epsilon^{3/4} + \epsilon^{1-p/2} \right). \]

The Gronwall inequality then yields

\[ \|R^u\|_{L^\infty_t L^p_x} \lesssim \epsilon^{3/4} + \epsilon^{1-p/2}, \]

which tends to zero as \( \epsilon \to 0 \), for \( p < 2 \). This ends the proof of the convergence (3.33), and thus of theorem 1.1.

Acknowledgments

The research of T N was supported in part by the Foundation Sciences Mathématiques de Paris under a postdoctoral fellowship and by the NSF under grant DMS-1108821.

The second author was partially supported by the Lefschetz Center for Dynamical Systems at Brown University and the Agence Nationale de la Recherche, Project CISIFS, grant ANR-09-BLAN-0213-02. He also warmly thanks the Division of Applied Mathematics at Brown University for their kind hospitality during his visit in April 2011.

The authors would like to thank Edriss Titi for drawing their attention to the reference [2].
