Abstract

Adult onset Still's disease (AOSD) is a rare disease in adults, in children also known as systemic juvenile idiopathic arthritis. We describe two patients with intermittent fevers without unknown origin. 27 years man and 75 years old woman, who presented with lymphadenopathy and recurrent fevers. There has been used intensive serologic, radiologic, laboratory investigation to exclude infectious diseases and malignancy. All the investigation showed no diagnosis. The clinical disease described for the first time at 11897 by Dr Still is finally diagnosed. Both patients received Anakinra with rapid response in hematologic, biochemical, and cytokine markers with reduction of systemic and local inflammation.

Keywords: Systemic JIA; Juvenile idiopathic arthritis; Remitting fever; Autoimmune; Macular or Maculopapular exanthema; Low-grade persistent fevers; Biologicals; IL-1B antagonist; Still's disease

Adult-onset Still's disease (AOSD)

AOSD is a rare systemic inflammatory disease of unknown etiologic that often presents as a fever of unknown origin. Systemic features, such as spiking fever, skin rash, generalized lymphadenopathy, hepatomegaly, splenomegaly, and serositis, was first described by the British paediatrician George F. Still [1] and by Bywaters in 14 patients [2]. The aetiology of AOSD still remains unknown, but overexpression of Th1 cytokines and IL-1 may have a critical role [3]. Pericarditis, pleural effusions, and severe abdominal pain may be present and confound diagnosis [4].

Daily fevers, evanescent rash, arthritis, hyperferritemia, and liver dysfunction were consistent with AOSD. Hyperferritemia has a high sensitivity for AOSD (80%) but has a low specificity (40%). The fraction of glycosylated ferritin is higher than with inflammatory conditions. The combination of elevated serum ferritin level and low (20%) fraction of glycosylated ferritin can make the diagnosis of AOSD most likely. In fact AOSD has similarities to auto inflammatory diseases, as exemplified by a central role of the innate immune system and by the cytokines involved (e.g., interleukin-1 [IL-1]). Moreover, the blocking of both IL-1 has been shown to be efficacious in the treatment of AOSD. An interleukin-1 (IL-1) antagonist, e.g., with the IL-1 receptor antagonist Anakinra, is the standard of therapy for the exacerbations of acute disease rather than increasing steroid use [5-9].

Case Reports

Case 1

A 27-year-old Caucasian male presented at his first admission with an episode of fever since 4 weeks, diffuse myalgia, sore throat, cold chills and fatigue. The patient was in his usual state of health until 1 month before admission, when he developed fever. He had an 18-pound weight loss over the preceding month. During the fever attacks he had fatigue. He did not report of sick symptoms, arthralgia, abdominal pain, nausea, diarrhoea, cough, dyspnoea, or a rash. He denied oral ulcers, ocular inflammation, photosensitivity, or Raynaud's phenomenon. He reported no pain or stiffness in the neck, low back, or heel. There was no history of recent travel, trauma, or sick contact. The patient's medical history was unremarkable except an episode of fever after a streptococcal infection ten years ago. There was no family history of autoimmune diseases. His medications upon admission were diclofenac 2 dd 100 mg.

Physical examination showed normal vital signs with fever of 40.0°C (104°F). The remainder of the physical examination was unremarkable.

Laboratory test revealed elevated inflammatory markers, including erythrocyte sedimentation rate (ESR; 116 mm/hour), C-reactive protein level (266 mg/liter). A peripheral leucocytosis was present, with a white blood cell count of 22,000/mm³ (normal range 4,500-11,000). WBCs, 90% neutrophils. The serum ferritin level was markedly increased at 5696 ng/ml (normal range 10-200). Urine cultures showed no infection and proteinuria was absent. An infectious disease evaluation was performed and was negative. Serologic study of Rheumatoid factor and anti nuclear antibody were negative.

Antibodies to Sm/RNP, Ro/SSA, and La/SSB; anti cardiolipin antibodies; ant neutrophil cytoplasmic antibodies (ANCAs); and anti-cyclic citrullinated peptide antibodies were negative, and creatine phosphokinase was normal. A chest radiograph
was normal. Transesophageal echocardiogram was performed by cardiologist the next day and ruled out endocarditis (no vegetation’s, some pericardial fluid).

After being well during 1 year after hospital discharge he complained of since 1 month existing fatigue, diarrhoea, nausea, vomiting, with fever up to 40.3°C (104.5°F). He had recognized dark urine and light coloured defecations. Physical examination at his second admission showed a sick patient with dry mucosa. Blood pressure 123/55, icteric skin, decreased skin turgor. Submandibular, right lateral sternocleidomastoid and right groin lymphadenopathy, all noduli seemed benign. Temperature was 38.9°degrees Celsius (101°F), the pulse rate was 122 beats/minute, and the respiratory rate was 12 breaths/minute. Abdomen is extended with normal bowel sounds, splenomegaly and hepatomegaly 10 cm below the costal arch. His liver function deteriorated and clotting indices were also deranged.

Liver biopsy showed non-specific inflammation (Figure 1). Prednisone 60 mg/day was started. The patient’s localized rash and fever resolved spontaneously. Liver function showed improvement. He was discharged from our hospital after 3 weeks.

Pathology Report

The biopsy of the liver and lymph nodule biopsy showed no typical sign of malignancy, tuberculosis infection, other infectious cause, sarcoidosis or Kikuchi disease. The only finding at histological examination was nonspecific reactive para cortical hyperplasia. Figure 1 shows the Liver biopsy from Case 1. There was no necrosis and only slight inflammation. Mediastinal biopsy and lung biopsy of patient B was negative for malignancy.

Case 2

75 years old women presented at our hospital with since months daily fevers between 38 to 39.5°C (100.4°-103.1°F) with night sweats. Her complaints were of fatigue, dizziness and nausea. Besides the febrile episode she felt well. Attacks of fever occurred sometimes 2 times a day and reached normal level. She lost 10 kilograms in 1 month. She was recent back from holiday in France. During holiday and before she had no contact with domestic animals, no tuberculosis contact, no erythematous rash, no photosensitivity, no Raynaud’s phenomenon, no ulcers, no stiffness over the muscles of the legs and arms, no visual or hearing problems. No jaw claudication and no arthrits. There was no family history of autoimmune disease. She had Diabetes Mellitus type II, atrium fibrillation in Medical history and used atenolol/chlortalidon 1 dd 100/25 mg, Metformin 2 dd 500 mg.

Physical examination revealed fully alert, oriented, and lucid sick women. Her vitals sign were as follows. Blood pressure 150/80 mm Hg, Heart beat 76/minute, her oxygen saturation was 95% on room air, and Temperature 37.8°C (100°F), her respiratory rate was 18 breaths/minute unlaboured. Unilateral right sided supraclavicular lymphadenopathy with right thyroid gland nodule. Examination of her heart revealed an irregular tachycardia (atrial flutter on ECG) but no murmurs, rubs, or gallops. The lungs were clear to auscultation. There was no evidence of hepatosplenomegaly, skin rash, focal motor weakness, sensory deficits or arthritis. Laboratory examination showed elevated inflammation levels (CRP 133 mg/L, BSE 48 mm/h). Leucocytes 13.1/nL Neutrophils 11/nL, Calcitonin 2 dd 500 mg.

Assays for antinuclear antibodies, antibodies to double stranded DNA, rheumatoid factor, anti-neutrophil cytoplasmic antibodies, anti-phospholipid antibodies, and cryo globulins were negative. The serum C3 and C4 levels were normal. A serum protein electrophoresis test showed normal levels of all immunoglobulin and no monoclonal spike. Blood cultures and a tuberculin test were negative. ECG: Atrial flutter. A complete work-up, including lymph node, bone marrow biopsy, was done to exclude malignancy. Her blood, stool, urine cultures and viral serology were all negative. All serologic examination was negative. Chest radiogram showed cardiomegaly. An ultrasound scan of the abdomen showed no abnormalities. CT thorax showed multiple pathologic mediastinal lymphomas (Figure 2).

Figure 1: Liver biopsy of Case 1, chronic non specific hepatitis, there was no necrosis and only slight inflammation at portal field.

Figure 2: Patient B Ct thorax: multiple lymph nodules increased in size Gantry 0 degrees, FoV: 312 mm, Time 500 ms, Slice 5 mm, 486 mA, 120 kV 14th slice from 75.
Pet scan revealed elevated uptake in multiple pathologic nodule high supraclavicular right and mediastinal. Mediastinal lymph nodule biopsy showed no malignant cells, only non-specific reactive para cortical hyperplasia. Cytological punction thyroid gland nodule was normal. Bronchoscopy showed no tumor.

During Hospital admission of 7 weeks, she had daily fever attacks with hypotension during febrile episode a 2 periods of 4-5 days without fever. Most of the febrile attacks occurred at night or early in the morning. At the beginning of the hospital stay were the levels of fever higher than compared with the last weeks. She developed during 2nd week pericarditis. Except for the fever attacks she was hemodynamic stable; only during a febrile attack she had hypotension and fatigue. She received Anakinra with clinical remission. There was an initial response without relapse.

General Discussion

These case reports illustrate that we have to carefully to assume a diagnosis of AOSD. There is no laboratory examination or histological findings that can be diagnostic for, which is purely a clinical diagnosis. Diagnostic criteria for AOSD are described by Yamaguchi et al. (Table 1) [6].

Table 1: Diagnostic criteria for adult onset still’s disease.

| Diagnostic criteria for adult onset Still’s disease | Yamaguchi’s Criteria | Fautrel’s Criteria |
|-----------------------------------------------------|----------------------|-------------------|
| Major Criteria                                      | 5 or more criteria are required, of whom 2 or more must be major | 4 or more major criteria are required, or 3 major and 2 minor criteria |
| Fever >39º, lasting one week or longer              | Major Criteria        | Major Criteria     |
| Arthralgia or arthritis, lasting 2 weeks or longer   | Spiking fever ≥ 39º    | Spiking fever ≥ 39º |
| Arthralgia or arthritis, lasting 2 weeks or longer   | Arthralgia            | Arthralgia         |
| Typical rash                                        | Transient erythema    | Transient erythema |
| Leukocytosis >10,000/mm³ with >80% polymorphonuclear cells | Pharyngitis | Pharyngitis |
|                                                    | Polymorphonuclear cells ≤ 80% | Polymorphonuclear cells ≤ 80% |
|                                                    | Glycosylated ferritin ≤ 20% | Glycosylated ferritin ≤ 20% |
| Minor Criteria                                      | Minor Criteria        | Minor Criteria     |
| Sore throat                                         | Maculopapular rash    | Maculopapular rash |
| Recent development of significant lymphadenopathy   | Leukocytosis ≥ 10,000/mm³ | Leukocytosis ≥ 10,000/mm³ |
| Hepatomegaly or Splenomegaly                        | Negative tests for antinuclear antibody (IF) and Rheumatoid factor (IgM) | Negative tests for antinuclear antibody (IF) and Rheumatoid factor (IgM) |
| Abnormal liver function tests                       |                      |                   |
| Negative tests for antinuclear antibody (IF) and    |                      |                   |
| Rheumatoid factor (IgM)                             |                      |                   |
| Exclusion Criteria                                  | Exclusion Criteria    | Exclusion Criteria |
| Infections                                          | -                    |                   |
| Malignancies (Mainly Malignant Lymphoma)            |                      |                   |
| Other Rheumatic Diseases (mainly Systemic vasculitides) |                      |                   |

Note: Several diagnostic criteria have been proposed, Yamaguchi’s and Fautrel’s criteria being the most employed

Exclusion of malignancies of the lymph reticular system is very important in establishing the diagnosis. Our patient’s intermittent fevers to greater than 38.3°C for more than 3 weeks meet the classic definition of fever of unknown origin (FUO). Reviews of large case series of FUO suggest that a primary inflammatory process is responsible for the fever in 22% of cases. Infection and malignancy account for 16% and 7%, respectively, and miscellaneous conditions account for an additional 16%. More than half of cases of FUO have remained without diagnoses in some series.

Case 1 met the 5 acquired criteria from which 2 major criteria for the Diagnosis of adult onset Still’s disease according to Yamaguchi et al. (Table 1) [6]. In Case 1 presented with 3 major criteria (spiking fever, pharyngitis, glycosylated ferritin <20%) and 3 minor criteria (maculopapular exanthema, leucocytosis of 22,000/mm³ WBC 90% neutrophils, abnormal liver enzyme tests). Case 2 had 2 major criteria according to Yamaguchi et al. (spiking fever >3ºC, had Leucocytosis 13,100 with 84% consisting from neutrophils). Case 2 had 2 minor criteria namely negative serologic tests for anti-nuclear antibody and reumatoid factor, Recently developed Lymphadenopathy. Case 2 had a few nodules supraclavicular. After radiological investigation there were multiple mediastinal nodules in Case 2. Malignancy especially Lymphoma and leukaemia are excluded by biopsy. High fever, rash, liver dysfunction, ferritin can be consistent with sepsis. Endocarditis should also be considered. Both patients thought to have an infection as most probable cause of fever. Serologic examination revealed no infectious cause. In both patients Cardiologist excluded an endocarditis. Case 2 had the 4 acquired major criteria according Fautrel (Table 1). Spiking fever longer than 2 weeks, Polymorphonuclear cells >80%, elevated ferritin from which glycosylated ferritin <20% and erythema. Case 2 had one minor criteria according to Fautrel namely leucocytosis. Both cases met the acquired criteria for diagnosis of AOSD. Yamaguchi criteria has been used for diagnosis of AOSD in case 1, Fautrel criteria for case 2.

Treatment of systemic juvenile idiopathic arthritis is similar to treatment of AOSD [6]. In the clinical department of affiliated Academic Centers is already frequently used as treatment treatment for AOSD. For the evidence that exists of the use of antagonists of IL-1B in the literature see references [6-10]. Role of IL1 in juvenile rheumatoid arthritis is already proven [11].

In case 1 the first 7 years after onset of AOSD corticosteroids and at fourth year from onset of AOSD is modifying anti rheumatoid drug (DMARD) Methotrexate (MTX) added with good response. Only after years and two severe relapses of AOSD by an unresponsive disease course treatment with DMARD MTX and corticosteroid is switched to biological IL-1B antagonist. Two months after start Anakinra 1 dd 100 mg as monotherapy, systemic inflammation and fever attacks improved. The liver function and inflammatory parameters are
normalized. Since start of the treatment with Anakinra no complaints or relapse of AOSD.

Case 2 did not receive corticosteroids as first choice because of presence of dysregulated diabetes mellitus type II. The use of corticosteroids have an unavoidable side effect on blood glucose levels on patients with Diabetes Mellitus that is dysregulated due to AOSD episode. Methotrexate is also bypassed by this patient. She had a 2 months long admission and effect of Methotrexate take weeks after intake. To shorten her quality of life as soon as possible, at second month of admission is the treatment with IL1B antagonist started. In other patients especially adult ones, the first choice of treatment remains corticosteroids and DMARDs.

Final Diagnosis

Adult Onset Still’s Disease.
