Abstract

Recent research in generalizing quantum computation from 2-valued qudits to \(d\)-valued qudits has shown practical advantages for scaling up a quantum computer. A further generalization leads to quantum computing with hybrid qudits where two or more qudits have different finite dimensions. Advantages of hybrid and \(d\)-valued gates (circuits) and their physical realizations have been studied in detail by Muthukrishnan and Stroud (Physical Review A, 052309, 2000), Daboul et al. (J. Phys. A: Math. Gen. 36 2525-2536, 2003), and Bartlett et al (Physical Review A, Vol.65, 052316, 2002). In both cases, a quantum computation is performed when a unitary evolution operator, acting as a quantum logic gate, transforms the state of qudits in a quantum system. Unitary operators can be represented by square unitary matrices. If the system consists of a single qudit, then Tilma et al (J. Phys. A: Math. Gen. 35 (2002) 10467-10501) have shown that the unitary evolution matrix (gate) can be synthesized in terms of its Euler angle parametrization. However, if the quantum system consists of multiple qudits, then a gate may be synthesized by matrix decomposition techniques such as QR factorization and the Cosine-sine Decomposition (CSD). In this article, we present a CSD based synthesis method for \(n\) qudit hybrid quantum gates, and as a consequence, derive a CSD based synthesis method for \(n\) qudit gates where all the qudits have the same dimension.

1 Introduction

A *qudit* replaces a classical dit as an information unit in $d$-valued quantum computing. A qudit is represented as a unit vector in the state space, which is a complex projective $d$-dimensional Hilbert space, $\mathcal{H}_d$. In the computational basis, the basis vectors of $\mathcal{H}_d$ are written in Dirac notation as $|0\rangle, |1\rangle, \ldots, |d-1\rangle$, where $|i\rangle = (0, 0, \ldots, 1, \ldots, 0)^T$ with a 1 in the $(i+1)$-st coordinate, for $0 \leq i \leq (d-1)$. An arbitrary vector $|a\rangle$ in $\mathcal{H}_d$ can be expressed as a linear combination $|a\rangle = \sum_{i=0}^{d-1} x_i |i\rangle$, $x_i \in \mathbb{C}$ and $\sum |x_i|^2 = 1$. The real number $|x_i|^2$ is the probability that the state vector $|a\rangle$ will be in $i$-th basis state upon measurement.

When the state spaces of $n$ qudits of different $d$-valued dimensions are combined via their algebraic tensor product, the result is a $n$ qudit hybrid state space $\mathcal{H} = \mathcal{H}_{d_1} \otimes \mathcal{H}_{d_2} \otimes \cdots \otimes \mathcal{H}_{d_n}$, where $\mathcal{H}_{d_i}$ is the state space of the $d_i$-valued qudit. The computational basis for $\mathcal{H}$ would consist of all possible tensor products of the computational basis vectors of the component state spaces $\mathcal{H}_{d_i}$. If $d_i = d$ for each $i$, the resulting state space $\mathcal{H}_d^\otimes n$ is that of $n d$-valued qudits.

The *evolution* of state space changes the state of the qudits via the action of a unitary operator on the qudits. A unitary operator can be represented by a unitary evolution matrix. For the hybrid state space $\mathcal{H}$, an evolution matrix will have size $(d_1d_2 \ldots d_N) \times (d_1d_2 \ldots d_N)$, while the evolution matrix for $\mathcal{H}_d^\otimes n$ will be of size $d^n \times d^n$. In the context of quantum logic synthesis, an evolution matrix is a quantum logic circuit that needs to be realized by a universal set of quantum logic gates. It is well established that sets of one and two qudit quantum gates are universal [3, 5, 10, 15]. Hence, the synthesis of an evolution matrix requires that the matrix be decomposed to the level of unitary matrices acting on one or two qudits.

Unitary matrix decomposition methods like the QR factorization and the Cosine Sine decomposition from matrix perturbation theory have been used for 2-valued and 3-valued quantum logic synthesis. In these domains, qudits are referred to as *qubits* and *qutrits* respectively. The Cosine Sine decomposition (CSD) of a unitary matrix, discussed in section 2, has been used by Möttönen et. al [9] and Shende et. al [12] to iteratively synthesize multi-qubit quantum circuits. The authors of this article recently extended the CSD to iterated synthesis of 3-valued quantum logic circuits acting on $n$ qutrits [8]. Bullock et.al have recently presented a synthesis method for $n$ qudit quantum logic gates using a variation of the QR matrix factorization [4]. This article presents a CSD based method for synthesis of $n$ qudit hybrid and $d$-valued quantum logic gates.
2 The Cosine-Sine Decomposition (CSD)

Let the unitary matrix $W \in \mathbb{C}^{m \times m}$ be partitioned in $2 \times 2$ block form as

$$W = \frac{r}{m-r} \begin{pmatrix} W_{11} & W_{12} \\ W_{21} & W_{22} \end{pmatrix}$$

(2.0.1)

with $2r \leq m$. Then there exist $r \times r$ unitary matrices $U$ and $X$, $r \times r$ real diagonal matrices $C$ and $S$, and $(m-r) \times (m-r)$ unitary matrices $V$ and $Y$ such that

$$W = \begin{pmatrix} U & 0 \\ 0 & V \end{pmatrix} \begin{pmatrix} C & -S & 0 \\ S & C & 0 \\ 0 & 0 & I_{m-2r} \end{pmatrix} \begin{pmatrix} X & 0 \\ 0 & Y \end{pmatrix}$$

(2.0.2)

The matrices $C$ and $S$ are the so-called cosine-sine matrices and are of the form $C = \text{diag}(\cos \theta_1, \cos \theta_2, \ldots, \cos \theta_r)$, $S = \text{diag}(\sin \theta_1, \sin \theta_2, \ldots, \sin \theta_r)$ such that $\sin^2 \theta_i + \cos^2 \theta_i = 1$ for some $\theta_i$, $1 \leq i \leq r$ [13]. Algorithms for computing the CSD and the angles $\theta_i$ are given in [2, 14]. The CSD is essentially the well known singular value decomposition of a unitary matrix implemented at the block matrix level [11]. In sections 3 and 4, we give an overview of the CSD based synthesis methods of 2 and 3-valued quantum logic circuits, respectively. From now on, we will not distinguish between gates, circuits and their corresponding unitary matrices.

3 Synthesis of 2-valued (binary) Quantum Logic Circuits

As shown in [8, 9, 12, 16], the CS decomposition gives a recursive method for synthesizing 2-valued and 3-valued $n$ qudit quantum logic gates. In the 2-valued case the CSD of a $2^n \times 2^n$ unitary matrix $W$ reduces to the form

$$W = \begin{pmatrix} U & 0 \\ 0 & V \end{pmatrix} \begin{pmatrix} C & -S \\ S & C \end{pmatrix} \begin{pmatrix} X & 0 \\ 0 & Y \end{pmatrix}$$

(3.0.1)

with each block matrix in the decomposition of size $2^{n-1} \times 2^{n-1}$.

In terms of synthesis, the block diagonal matrices in (3.0.1) are quantum multiplexers [12]. A quantum multiplexer is a gate acting on $n$ qubits of which one is designated as the control qubit. If the control qubit is the highest order qubit, the multiplexer matrix is block diagonal. Depending on whether the control qubit carries $|0\rangle$ or $|1\rangle$, the gate then performs either the top left block
or the bottom right block of the $n \times n$ block diagonal matrix on the remaining $(n - 1)$ qubits. A circuit diagram for a $n$ qubit quantum multiplexer with the highest order control qubit is given in figure 1. Observe that we decomposed arbitrary quantum multiplexer to single qubit gates and $n$ qubit standard controlled gates. The controlled gates execute the operator in the box when the controlling qubit has values 1 (mod 2). Such a quantum multiplexer can be expressed as

$$
\begin{pmatrix}
U_0 & 0 \\
0 & U_1
\end{pmatrix}
(|a_1\rangle \otimes |a_2\rangle \otimes \cdots \otimes |a_n\rangle)
$$

(3.0.2)

where $|a_i\rangle$ is the $i$-th qubit in the circuit, and both block matrices $U_0$ and $U_1$ are of size $2^{n-1} \times 2^{n-1}$. Depending on whether $|a_1\rangle = |0\rangle$ or $|a_1\rangle = |1\rangle$, the expression (3.0.2) reduces to

$$
|0\rangle \otimes U_0 (|a_2\rangle \otimes |a_3\rangle \otimes \cdots \otimes |a_n\rangle)
$$

(3.0.3)

or

$$
|1\rangle \otimes U_1 (|a_2\rangle \otimes |a_3\rangle \otimes \cdots \otimes |a_n\rangle)
$$

(3.0.4)

respectively.

The cosine-sine matrix in (3.0.1) is realized as a uniformly $(n - 1)$-controlled $R_y$ rotation gate, a variation of the quantum multiplexer. As shown in figure 2, a uniformly $(n - 1)$-controlled $R_y$ rotation gate $R_y$ is composed of a sequence of $(n - 1)$-fold controlled gates $R_y^{\theta_i}$, all acting on the highest order qubit, where

$$
R_y^{\theta_i} = \begin{pmatrix}
\cos \theta_i - \sin \theta_i \\
\sin \theta_i & \cos \theta_i
\end{pmatrix}.
$$

(3.0.5)

The control selecting the angle $\theta_i$ in the gate $R_y^{\theta_i}$ depends on which of the $(n - 1)$ basis state configurations the control qubits are in at that particular stage in the circuit. In figure 2, the open controls represent the basis state $|0\rangle$ and a filled in control represents basis state $|1\rangle$. The $i$-th $(n - 1)$-controlled
Fig. 2. A uniformly \((n - 1)\)-controlled \(R_y\) rotation for 2-valued quantum logic. The lower \((n - 1)\) qubits are the control qubits represented on the left hand side by the symbol / on the second wire. The \(\circ\) control turns on for control value \(|0\rangle\) and the \(\bullet\) control turns on for control value \(|1\rangle\). It requires \(2^{n-1}\) one qubit controlled gates \(R^\theta_y\) to implement a uniformly \((n - 1)\)-controlled \(R_y\) rotation.

\[
\begin{pmatrix}
\cos \theta_i - \sin \theta_i \\
\sin \theta_i & \cos \theta_i
\end{pmatrix}
|a_1\rangle \otimes (|a_2\rangle \otimes \cdots \otimes |a_n\rangle)
\] (3.0.6)

with \(\theta_i\) taking on values from the set \(\{\theta_0, \theta_1, \ldots, \theta_{2^{n-1}-1}\}\) depending on the configuration of \((|a_2\rangle \otimes \cdots \otimes |a_n\rangle)\), resulting in a specific \(R^\theta_y\) for each \(i\).

As an example, consider the 3 qubit uniformly 2-controlled \(R_y\) gate controlling the top qubit from figure 4. Then the action of \(R^\theta_y\) on the circuit is

\[
\begin{pmatrix}
\cos \theta_i - \sin \theta_i \\
\sin \theta_i & \cos \theta_i
\end{pmatrix}
|a_1\rangle \otimes (|a_2\rangle \otimes |a_3\rangle)
\] (3.0.7)

with \(\theta_i \in \{\theta_0, \theta_1, \theta_2, \theta_3\}\). As \(|a_2\rangle \otimes |a_3\rangle\) takes on the values from the set \(\{|0\rangle \otimes |0\rangle, |0\rangle \otimes |1\rangle, |1\rangle \otimes |0\rangle, |1\rangle \otimes |1\rangle\}\) in order, the expression in (3.0.7) reduces to the following 4 expressions respectively.

\[
\begin{pmatrix}
\cos \theta_0 - \sin \theta_0 \\
\sin \theta_0 & \cos \theta_0
\end{pmatrix}
|a_1\rangle \otimes (|0\rangle \otimes |0\rangle)
\] (3.0.8)
Fig. 5. 3-valued Quantum Multiplexer \( M \) controlling the lower \((n-1)\) qutrits via the top qutrit. The slash symbol (/) represents \((n-1)\) qutrits on the second wire. The gates labeled +2 are shift gates, increasing the value of the qutrit by 2 mod 3, and the control \( \diamond \) turns on for input \(|2\rangle\). Depending on the value of the top qutrit, one of \( U_t \) is applied to the lower qutrits for \( t \in \{0, 1, 2\} \).

\[
\begin{pmatrix}
\cos \theta_1 & -\sin \theta_1 \\
\sin \theta_1 & \cos \theta_1
\end{pmatrix}
|a_1\rangle \otimes (|0\rangle \otimes |1\rangle) \tag{3.0.9}
\]

\[
\begin{pmatrix}
\cos \theta_2 & -\sin \theta_2 \\
\sin \theta_2 & \cos \theta_2
\end{pmatrix}
|a_1\rangle \otimes (|1\rangle \otimes |0\rangle) \tag{3.0.10}
\]

\[
\begin{pmatrix}
\cos \theta_3 & -\sin \theta_3 \\
\sin \theta_3 & \cos \theta_3
\end{pmatrix}
|a_1\rangle \otimes (|1\rangle \otimes |1\rangle) \tag{3.0.11}
\]

4 CSD Synthesis of 3-valued (ternary) Quantum Logic Circuits

In the 3-valued case, two applications of the CSD are needed to decompose a \( 3^n \times 3^n \) unitary matrix \( W \) to the point where every block in the decomposition has size \( 3^{n-1} \times 3^{n-1} \) [8]. Choose the parameters \( m \) and \( r \) given in (2.0.1) as \( m = 3^n \) and \( r = 3^{n-1} \), so that \( m - r = 3^n - 3^{n-1} = 3^{n-1}(3 - 1) = 3^{n-1} \cdot 2 \). The CS decomposition of \( W \) will now take the form in (2.0.2), with the matrix blocks \( U \) and \( X \) of size \( 3^{n-1} \times 3^{n-1} \) and blocks \( V \) and \( Y \) of size \( 3^{n-1} \cdot 2 \times 3^{n-1} \cdot 2 \). Repeating the partitioning process for the blocks \( V \) and \( Y \) with \( m = 3^{n-1} \cdot 2 \) and \( r = 3^{n-1} \), and decomposing them with CSD followed by some matrix factoring will give rise to a decomposition of \( W \) involving unitary blocks each of size \( 3^{n-1} \) as follows.

\[
W = ABC \begin{pmatrix}
C & -S & 0 \\
S & C & 0 \\
0 & 0 & I
\end{pmatrix} DEF \tag{4.0.1}
\]
Fig. 6. A uniformly \((n - 1)\)-controlled \(R_x\) rotation. The lower \((n - 1)\) qutrits are the control qutrits represented on the left hand side by the symbol / on the second wire. The controls ◯, ●, and ♦ turn on for inputs \(|0\rangle\), \(|1\rangle\), and \(|2\rangle\) respectively. It requires \(3^{n-1}\) one qutrit controlled gates to implement a uniformly \((n - 1)\)-controlled \(R_x\) or \(R_z\) rotation.

Fig. 7. A control by the value 0 (mod 3) realized in terms of control by the highest value 2 (mod 3).

Fig. 8. A control by the value 1 (mod 3) realized in terms of control by the highest value 2 (mod 3).

with

\[
A = \begin{pmatrix} X_1 & 0 & 0 \\ 0 & X_2 & 0 \\ 0 & 0 & X_3 \end{pmatrix}, \quad B = \begin{pmatrix} I & 0 & 0 \\ 0 & C_1 & -S_1 \\ 0 & S_1 & C_1 \end{pmatrix}, \quad C = \begin{pmatrix} I & 0 & 0 \\ 0 & Z_1 & 0 \\ 0 & 0 & Z_2 \end{pmatrix} \tag{4.0.2}
\]

\[
D = \begin{pmatrix} Y_1 & 0 & 0 \\ 0 & Y_2 & 0 \\ 0 & 0 & Y_3 \end{pmatrix}, \quad E = \begin{pmatrix} I & 0 & 0 \\ 0 & C_2 & -S_2 \\ 0 & S_2 & C_2 \end{pmatrix}, \quad F = \begin{pmatrix} I & 0 & 0 \\ 0 & W_1 & 0 \\ 0 & 0 & W_2 \end{pmatrix} \tag{4.0.3}
\]

We realize each block diagonal matrix in (4.0.2) and (4.0.3) as a 3-valued quantum multiplexer acting on \(n\) qutrits of which the highest order qutrit is designated as the control qutrit. Depending on which of the values \(|0\rangle\), \(|1\rangle\), or \(|2\rangle\) the control qutrit carries, the gate then performs either the top left block, the middle block, or the bottom right block respectively on the remaining \(n - 1\) qutrits. Figure 5 gives the layout for a \(n\) qutrit quantum multiplexer realized in terms of Muthukrishnan-Stroud (MS) gates. The MS gate is a \(d\)-valued generalization of the controlled-not (CNOT) gate from 2-valued quantum logic, and allows for control of one qudit by the other via the highest value of a \(d\)-valued quantum system, which in the 3-valued case is 2 [10].
Fig. 9. An n qudit hybrid quantum multiplexer, here realized in terms of Muthukrishnan-Stroud (d-valued controlled) gates. The top qudit has dimension $d_i$ and controls the remaining $(n - 1)$ qudits of possibly distinct dimensions which are represented here by the symbol (/). The control $\otimes$ turns on for input value $|d_i - 1\rangle \mod d_i$ of the controlling signal coming from the top qudit. The gates $+(d_i - 1)$ shift the values of control qudit by $(d_i - 1) \mod d_i$.

The cosine-sine matrices are realized as the uniformly $(n - 1)$-controlled $R_x$ and $R_z$ rotations in $\mathbb{R}^3$. Similar to the 2-valued case, each $R_x$ and $R_z$ rotation is composed of a sequence of $(n - 1)$-fold controlled gates $R^\theta_x$ or $R^\phi_z$, where

$$R^\theta_x = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos \theta_i - \sin \theta_i & 0 \\ 0 & \sin \theta_i & \cos \theta_i \end{pmatrix}, \quad R^\phi_z = \begin{pmatrix} \cos \phi_i - \sin \phi_i & 0 \\ \sin \phi_i & \cos \phi_i & 0 \\ 0 & 0 & 1 \end{pmatrix}. \quad (4.0.4)$$

Each $R^\theta_x$ or $R^\phi_z$ operator is applied to the top most qutrit, with the value of the angles $\theta_i$ and $\phi_i$ determined by the $(n - 1)$ basis state configurations of the control qutrits. A uniformly controlled $R_x$ gate is shown in figure 6. Figures 7 and 8 explain the method to create controls of maximum value. The value of the control qubit is always restored in figures 7 and 8.

5 Synthesis of Hybrid and $d$-valued Quantum Logic Circuits

It is evident from the 2 and 3-valued cases above that the CSD method of synthesis is of a general nature and can be extended to synthesis of $d$-valued gates acting on $n$ qudits. In fact, it can be generalized for synthesis of hybrid $n$ qudit gates. We propose that a $(d_1d_2 \ldots d_n) \times (d_1d_2 \ldots d_n)$ block diagonal unitary matrix be regarded as a quantum multiplexer for an $n$ qudit hybrid quantum state space $\mathcal{H} = \mathcal{H}_{d_1} \otimes \mathcal{H}_{d_2} \otimes \cdots \otimes \mathcal{H}_{d_n}$, where $\mathcal{H}_{d_i}$ is the state space of the $i$ qudit.

Moreover, consider a cosine-sine matrix of size $(d_1d_2 \ldots d_n) \times (d_1d_2 \ldots d_n)$ of
Fig. 10. A hybrid uniformly \((n - 1)\)-controlled Givens rotation. The lower \((n - 1)\) qudits of dimensions \(d_2, d_3, \ldots, d_{i-1}, d_{i+1}, \ldots, d_n\), respectively, are the control qudits, and the top is the target qudit of dimension \(d_i\). The control gate \(d_l^{(k)}\) turns on whenever the control qudit of dimension \(d_l\) takes on the value \(k \pmod{d_l}\).

the form

\[
\begin{pmatrix}
I_p & 0 & 0 & 0 \\
0 & C & -S & 0 \\
0 & S & C & 0 \\
0 & 0 & 0 & I_q
\end{pmatrix}
\]

(5.0.1)

with \(I_p\) and \(I_q\) both some appropriate sized identity matrices, \(C = \text{diag}(\cos \theta_1, \cos \theta_2, \ldots, \cos \theta_t)\) and \(S = \text{diag}(\sin \theta_1, \sin \theta_2, \ldots, \sin \theta_t)\) such that \(\sin^2 \theta_i + \cos^2 \theta_i = 1\) for some \(\theta_i\) with \(1 \leq i \leq t\), and \(p + q + 2t = (d_1 d_2 \ldots d_n)\). We regard this matrix as a uniformly controlled Givens rotation matrix, a generalization of the \(R_y\), \(R_x\), and \(R_z\) rotations of the 2 and 3-valued cases. A Givens rotation matrix has the general form

\[
G_{(i,j)}^\theta = \begin{pmatrix}
1 & \ldots & 0 & \ldots & 0 & \ldots & 0 \\
\vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\
0 & \ldots & \cos \theta & \ldots & -\sin \theta & \ldots & 0 \\
\vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\
0 & \ldots & \sin \theta & \ldots & \cos \theta & \ldots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\
0 & \ldots & 0 & \ldots & 0 & \ldots & 1
\end{pmatrix}
\]

(5.0.2)

where the cosine and sine values reside in the intersection of the \(i\)-th and \(j\)-th rows and columns, and all other diagonal entries are 1 [7]. Hence, a Givens rotation matrix corresponds to a rotation by some angle \(\theta\) in the \(ij\)-th hyperplane.
Based on the preceding discussion, we give in theorem 5.1.1 below an iterative CSD method for synthesizing a \( n \) qudit hybrid quantum circuit by decomposing the corresponding unitary matrix of size \( (d_1d_2\ldots d_n) \times (d_1d_2\ldots d_n) \) in terms of quantum multiplexers and uniformly controlled Givens rotations. As a consequence of this theorem, we give in lemma 5.1.1 a CSD synthesis of a quantum quantum logic circuit with corresponding unitary matrix of size \( d_n \times d_n \). The synthesis methods given above for 2-valued and 3-valued circuits may then be treated as special cases of the former.

5.1 Hybrid Quantum Logic Circuits

Consider a hybrid quantum state space of a \( n \) qudits, \( \mathcal{H} = \mathcal{H}_{d_1} \otimes \mathcal{H}_{d_2} \otimes \cdots \otimes \mathcal{H}_{d_n} \), where each qudit may be of distinct \( d \)-valued dimension \( d_i \), \( 0 \leq i \leq n \). Since a qudit in \( \mathcal{H} \) is a column vector of length \( d_1d_2\ldots d_n \), a quantum logic gate acting on such a vector is a \( (d_1d_2\ldots d_N) \times (d_1d_2\ldots d_n) \) unitary matrix \( W \). We will decompose \( W \), using CSD iteratively, from the level of \( n \) qudits to \( (n-1) \) qudits in terms of quantum multiplexers and uniformly controlled Givens rotations. However, since the \( d \)-valued dimension may be different for each qudit, the block matrices resulting from the CS decomposition may not be of the form \( d_n^{-1} \times d_n^{-1} \) for some \( d \). Therefore, we proceed by choosing one of the qudits, \( c_{d_i} \), of dimension \( d_i \), to be the control qudit and order of the basis of \( \mathcal{H} \) in such a way that \( c_{d_i} \) is the highest order qudit. We will decompose \( W \) with respect to \( c_{d_i} \) so that the resulting quantum multiplexers are controlled by \( c_{d_i} \) and the uniformly controlled Givens rotations control \( c_{d_i} \) via the remaining \( (n-1) \) qudits. We give the synthesis method in theorem 5.1.1.

**Theorem 5.1.1:** Let \( W \) be an \( M \times M \) unitary matrix, with \( M = d_1d_2\ldots d_n \), acting as a quantum logic gate on a quantum hybrid state space \( \mathcal{H} = \mathcal{H}_{d_1} \otimes \mathcal{H}_{d_2} \otimes \cdots \otimes \mathcal{H}_{d_n} \) of \( n \) qudits. Then \( W \) can be synthesized with respect to a control qudit \( c_{d_i} \) of dimension \( d_i \), having the highest order in \( \mathcal{H} \), iteratively from level \( n \) to level \( (n-1) \) in terms of quantum multiplexers and uniformly controlled Givens rotations.

**Proof.**

**Step 1.** At level \( n \), identify a control qudit \( c_{d_i} \) of dimension \( d_i \). Reorder the basis of \( \mathcal{H} \) so that \( c_{d_i} \) is the highest order qudit and the new state space isomorphic to \( \mathcal{H} \) is \( \mathcal{H} = \mathcal{H}_{d_i} \otimes \mathcal{H}_{d_2} \otimes \cdots \otimes \mathcal{H}_{d_i} \otimes \cdots \otimes \mathcal{H}_{d_n} \).
If we choose values for the CSD parameters $m$ and $r$ as $m = (d_1 d_2 \ldots d_n)$ and $r = (d_1 d_2 \ldots d_{i-1} d_{i+1} \ldots d_n)$, then $m - r = d_1 \ldots d_{i-1} d_{i+1} \ldots d_n (d_i - 1)$. Decomposing $W$ by CSD, we get the form in (2.0.2) with the matrix blocks $U$ and $X$ of size $r \times r$ and blocks $V$ and $Y$ of size $(m - r) \times (m - r)$. Should $m - r$ not have the factor $(d_i - 1)$, we would achieve the desired decomposition of $W$ from level of $n$ qudits to the level of $(n - 1)$ qudits in terms of block matrices of size $r \times r$. The task therefore is to divide out the factor $(d_i - 1)$ from $m - r$ by an iterative lateral decomposition described below, that uses the CSD to cancel $(d_i - 1)$ from $m - r$ at each iteration level leaving only blocks of size $r \times r$.

For step 2 of the proof below, we will say that a matrix with $k$ rows and $k$ columns has size $k$ instead of $k \times k$.

**Step 2. Iterative Lateral Decomposition:** For the unitary matrix $W$ of size $M$, we define the $j$-th lateral decomposition of $W$ as the CS decomposition of all block matrices of size other than $r$ that result from the $(j - 1)$-st lateral decomposition of $W$:

For $0 \leq j \leq (d_i - 2)$, set

$m_0 = (d_1 d_2 \ldots d_n)$

$r_0 = (d_1 d_2 \ldots d_{i-1} d_{i+1} \ldots d_n)$

If $j = 0$

Apply CSD to $W$

Else set

$m_j = m_0 - j \cdot r_0$

$r_j = r_0$

$m_j - r_j = m_0 - (j + 1) r_0$

$= (d_1 d_2 \ldots d_{i-1} d_{i+1} \ldots d_n) [d_i - (j + 1)]$

$m_j - 2r_j = m_0 - (j + 2) r_0$

$= (d_1 d_2 \ldots d_{i-1} d_{i+1} \ldots d_n) [d_i - (j + 2)]$

Apply CSD to matrix blocks of size other than $r_0$ from step $j - 1$

End If

End For.

When $j = 0$, we call the resulting 0-th lateral decomposition the global decomposition. Note that if $d_i = 2$, then the algorithm for the lateral decomposition stops after the global decomposition. This suggests that whenever feasible, the control system in the quantum circuit should be 2-valued so as to reduce the number of iterations. Below we give a matrix description of the algorithm.

For $j = 0$, the 0-th lateral decomposition of $W$ will just be the CS decomposition of $W$.

$$W = A_0^{(0)} B_0^{(0)} C_0^{(0)}$$  \hspace{1cm} (5.1.1)
where

\[
A_0^{(0)} = \begin{pmatrix}
U_0^{(0)} & 0 \\
0 & V_0^{(0)}
\end{pmatrix},
B_0^{(0)} = \begin{pmatrix}
C_0^{(0)} & -S_0^{(0)} & 0 \\
S_0^{(0)} & C_0^{(0)} & 0 \\
0 & 0 & I_{m_0-2r_0}
\end{pmatrix},
C_0^{(0)} = \begin{pmatrix}
X_0^{(0)} & 0 \\
0 & Y_0^{(0)}
\end{pmatrix}
\]

with \(U_0^{(0)}, X_0^{(0)}, C_0^{(0)}, \) and \(S_0^{(0)}\) all of the desired size \(r_0\), while \(V_0^{(0)}\) and \(Y_0^{(0)}\) are of size \(m_0 - r_0\). The superscripts label the iteration step, in this case \(j = 0\). The subscript is used to distinguish between the various matrix blocks \(U, V, X, Y, C, S\), that occur at the various levels of iteration. The 0-th lateral decomposition in the form from equation (5.1.1) is called the global decomposition of \(W\).

For \(j = 1\), we perform lateral decomposition on the blocks \(V_0^{(0)}\) and \(Y_0^{(0)}\) of the block matrices \(A_0^{(0)}\) and \(C_0^{(0)}\) respectively, the only blocks of size other than \(r_0\) resulting from the 0-th lateral decomposition given in (5.1.1). In both cases, set \(m_1 = m_0 - r_0\) and \(r_1 = r_0\) so that \(m_1 - r_1 = m_0 - 2r_0\). For \(V_0^{(0)}\) this gives the decomposition

\[
A_0^{(0)} = \begin{pmatrix}
U_0^{(0)} \\
0 \\
V_0^{(1)}
\end{pmatrix} \begin{pmatrix}
C_0^{(1)} - S_0^{(1)} & 0 \\
S_0^{(1)} & C_0^{(1)} \\
0 & 0 & I_{m_0-3r_0}
\end{pmatrix} \begin{pmatrix}
X_0^{(1)} & 0 \\
0 & Y_0^{(1)}
\end{pmatrix}
\]

with \(U_0^{(1)}, X_0^{(1)}, C_0^{(1)}\) and \(S_0^{(1)}\) all of size \(r_0\), and \(V_0^{(1)}\) and \(Y_0^{(1)}\) of size \(m_1 - r_1\). All three matrices residing in the lower block diagonal of the matrix (5.1.2) are the same size. Therefore, by introducing identity matrices of size \(r_0\) and factoring out at the matrix block level, \(A_0^{(0)}\) will be updated to

\[
A_0^{(0)} = A_0^{(1)} B_0^{(1)} C_0^{(1)}
\]

where

\[
A_0^{(1)} = \begin{pmatrix}
U_0^{(0)} & 0 & 0 \\
0 & U_0^{(1)} & 0 \\
0 & 0 & V_0^{(1)}
\end{pmatrix},
B_0^{(1)} = \begin{pmatrix}
I_{r_0} & 0 & 0 \\
0 & C_0^{(1)} - S_0^{(1)} & 0 \\
0 & S_0^{(1)} & C_0^{(1)}
\end{pmatrix},
C_0^{(1)} = \begin{pmatrix}
I_{r_0} & 0 & 0 \\
0 & X_0^{(1)} & 0 \\
0 & 0 & Y_0^{(1)}
\end{pmatrix}
\]

A similar lateral decomposition of the block \(Y_0^{(0)}\) will update \(C_0^{(0)}\) in (5.1.1) to

\[
C_0^{(0)} = A_1^{(1)} B_1^{(1)} C_1^{(1)}
\]
where

\[
A_1^{(1)} = \begin{pmatrix} X_0^{(0)} & 0 & 0 \\ 0 & U_1^{(1)} & 0 \\ 0 & 0 & V_1^{(1)} \end{pmatrix}, \quad B_1^{(1)} = \begin{pmatrix} I_{r_0} & 0 & 0 \\ 0 & C_1^{(1)} - S_1^{(1)} & 0 \\ 0 & S_1^{(1)} & C_1^{(1)} \end{pmatrix}, \quad C_1^{(1)} = \begin{pmatrix} I_{r_0} & 0 & 0 \\ 0 & X_1^{(1)} & 0 \\ 0 & 0 & Y_1^{(1)} \end{pmatrix}
\]

For iteration \( j \neq 0 \), perform lateral decomposition on the total \( 2^j \) blocks \( V_k^{(j-1)}, Y_k^{(j-1)} \), where \( 0 \leq k \leq (j - 1) \), that occur in the global decomposition at the end of iteration \((j - 1)\). For each \( V_k^{(j-1)}, Y_k^{(j-1)} \), set \( r_j = r_0, m_j = m_j - 1 - r_j = m_0 - (j + 1)r_0 \). For each \( V_k^{(j-1)} \), the lateral decomposition at level \( j \) will give the following

\[
A_k^{(j)} = \begin{pmatrix} \Delta^{(j-1)} & 0 & 0 \\ 0 & C_k^{(j)} & S_k^{(j)} \end{pmatrix}, \quad B_k^{(j)} = \begin{pmatrix} I_{r_0} & 0 & 0 \\ 0 & C_k^{(j)} - S_k^{(j)} & 0 \\ 0 & S_k^{(j)} & C_k^{(j)} \end{pmatrix}, \quad C_k^{(j)} = \begin{pmatrix} I_{r_0} & 0 & 0 \\ 0 & X_k^{(j)} & 0 \\ 0 & 0 & Y_k^{(j)} \end{pmatrix}
\]

where the \( \Delta^{(j-1)} \) is the block diagonal matrix of size of \( j \cdot r_0 \) arising from the lateral decomposition in the previous \((j - 1)\) steps. The blocks \( U_k^{(j)}, X_k^{(j)}, C_k^{(j)} \) and \( S_k^{(j)} \) are all of size \( r_0 \), for \( 0 \leq k \leq j \). The blocks \( V_k^{(j)} \) and \( Y_k^{(j)} \) are of size \( m_j - r_j \). The three matrices residing in the lower block diagonal of the matrix \((5.1.5)\) are all of same size. Therefore, by introducing identity matrices of size \( j \cdot r_0 \) and factoring out at the block level, \( A_k^{(j)} \) will be updated to

\[
A_k^{(j)} = A_{k'}^{(j+1)} B_{k'}^{(j+1)} C_{k'}^{(j+1)}
\]

where

\[
A_{k'}^{(j)} = \begin{pmatrix} \Delta^{(j-1)} & 0 & 0 \\ 0 & U_{k'}^{(j)} & 0 \\ 0 & 0 & V_{k'}^{(j)} \end{pmatrix}, \quad B_{k'}^{(j)} = \begin{pmatrix} I_{r_0} & 0 & 0 \\ 0 & C_{k'}^{(j)} - S_{k'}^{(j)} & 0 \\ 0 & S_{k'}^{(j)} & C_{k'}^{(j)} \end{pmatrix}, \quad C_{k'}^{(j)} = \begin{pmatrix} I_{r_0} & 0 & 0 \\ 0 & X_{k'}^{(j)} & 0 \\ 0 & 0 & Y_{k'}^{(j)} \end{pmatrix}
\]

For the next iteration, set \( k = k' \) and iterate. Upon completion of the lateral decomposition, repeat steps 1 and 2 for the synthesis of the circuit for the remaining \((n - 1)\) qudits, with the restriction that each gate in the remaining circuit be decomposed with respect to the same control qudit identified in step 1.
Since the basis for $\mathcal{H}$ was reordered in the beginning so that the control qudit was of the highest order, the block diagonal matrices with all blocks of size $r_0 \times r_0$ are interpreted as quantum multiplexers and the cosine-sine matrices are interpreted as uniformly controlled Givens rotations. In figures 9 and 10, we present the circuit diagrams of a hybrid quantum multiplexer and a uniformly controlled Givens rotation, respectively. A uniformly controlled Givens rotation matrix on $n$ qudits can be realized as the composition of various $(n-1)$-fold controlled Givens rotation matrices, $G_{(i,j)}^{d_k}$, acting on the top most qudit of the circuit with the angle of rotation depending on the basis state configuration, in their respective dimensions, of the lower $(n-1)$ qudits.

5.2 $d$-valued Quantum Logic Circuits

Given the hybrid $n$ qudit synthesis, the case of $d$-valued synthesis becomes a special case of the former since by setting all $d_i = d$, the state space $\mathcal{H} = \mathcal{H}_{d_1} \otimes \mathcal{H}_{d_2} \otimes \cdots \otimes \mathcal{H}_{d_n}$ reduces to the state space $\mathcal{H}^\otimes n$. Unitary operators acting on the states in $\mathcal{H}^\otimes n$ are unitary matrices of size $d^n \times d^n$. We give the following result for $d$-valued synthesis.

**Lemma 5.1.1:** A $d$-valued $n$ qudit quantum logic gate can be synthesized in terms of quantum multiplexers and uniformly controlled Givens rotations.

**Proof:** Since all the qudits are of the same dimension, there is no need to choose a control qudit. In the proof of theorem 5.1.1, set $d_i = d$ for all $i$. Then $M = d_1d_2\ldots d_n = d^n$. For iteration $j = 0$ of the lateral decomposition, set $m_0 = d^n$, $r_0 = d^{n-1}$, so that $m_0 - r_0 = d^{n-1}(d-1)$. For $0 \leq j \leq (d-2)$, set $r_j = r_0 = d^{n-1}$, and $m_j = m_{j-1} - r_{j-1} = d^{n-1}(d-(j+1))$.

For the $d$-valued case, we note that there are a total of $d^{n-1}(2d-1-1)$ one qudit Givens rotations in the circuit at the $(n-1)$ level, each arising from the $\sum_{i=0}^{d-2} 2^i = 2^{d-1} - 1$ uniformly controlled Givens rotations in the CS decomposition of an $n$ qudit gate. Moreover, in each uniformly controlled Givens rotation, there are $(n-1)d^{n-2}$ control symbols of which $(n-1)d^{n-2}$ correspond to control by the highest value of $d-1$. The latter controls do not require shift gates around them to increase the value of the signal qudit to $d-1$. Hence, there are $(n-1)d^{n-1}-(n-1)d^{n-2} = (n-1)(d^{n-1}-d^{n-2})$ control symbols that correspond to control by values other than $d-1$ and therefore need two shift gates (fig. 11) around them. This gives the total number of one qudit shift gates in each uniformly controlled rotation to be $2(n-1)(d^{n-1}-d^{n-2})$, whereby the total number of one qudit shifts and Givens rotations in the circuit at the $(n-1)$ level is $2(n-1)(d^{n-1}-d^{n-2})(2^{d-1}-1) + d^{n-1}(2^{d-1}-1) = (2^{d-1}-1)[2(n-1)(d^{n-1}-d^{n-2}) + d^{n-1}]$.

There are $2^{d-1}$ quantum multiplexers in the decomposition, each consisting of
a total of $2d$ shift and controlled gates. Hence, there are a total of $d \cdot 2^d$ one qudit and controlled gates in the $(n-1)$ level circuit. This gives a total, worst case, one qudit and controlled gate count in the circuit at level $(n-1)$ to be $(2^{d-1} - 1) [2(n-1)(d^{n-1} - d^{n-2}) + d^{n-1}] + d \cdot 2^d$.

6 Conclusion

We have shown that the method of CS decomposition of unitary matrices used in 2-valued and 3-valued quantum logic synthesis is a special case of a general synthesis method based on the CSD. We give an algorithm for this general method that allows us to synthesize $n$ qudit hybrid and $d$-valued quantum logic circuits in terms of quantum multiplexers and uniformly controlled Givens rotations.
