ON LATTICES WITH FINITE COULOMBIAN INTERACTION ENERGY IN THE PLANE

YUXIN GE AND ETIENNE SANDIER

Abstract. We present criteria for the Coulombian interaction energy of infinitely many points in the plane with a uniformly charged background introduced in [5] to be finite, as well as examples. We also show that in this unbounded setting, it is not always possible to project an $L^2_{loc}$ vector field onto the set of gradients in a way that reduces its average $L^2$ norm on large balls.

1. Introduction

Given a discrete set $\Lambda$ in the plane (we will also say a lattice) and a real number $m \geq 0$, the renormalized energy introduced in [5] heuristically describes the interaction energy of unit charges placed at the points of $\Lambda$ with a uniform negative background of density $m \in \mathbb{R}$. It is defined in several steps, following mostly [5].

First, denoting $\nu := \sum_{p \in \Lambda} \delta_p$ and for any vector-field $j$ solving

$$-	ext{div}(j) = 2\pi (\nu - m) \text{ in } \mathbb{R}^2,$$

and belonging to $L^2_{loc}(\mathbb{R}^2 \setminus \Lambda, \mathbb{R}^2)$ we define $W(j)$ as follows: For any $R > 1$ we denote by $\chi_R$ a smooth approximation of the indicator function of $B_R$, the ball centered at 0 with radius $R$. More precisely we assume that

$$\chi_R \geq 0, \|\nabla \chi_R\|_\infty \leq C, \chi_R \equiv 1 \text{ on } B_{R-1} \text{ and } \chi_R \equiv 0 \text{ on } \mathbb{R}^2 \setminus B_R,$$

where $C$ is independent of $R$. Then we let

$$W(j) := \limsup_{R \to \infty} \frac{W(j, \chi_R)}{|B_R|}, \quad W(j, \chi_R) := \limsup_{\eta \to 0} \frac{1}{2} \int_{\mathbb{R}^2 \setminus \bigcup_{p \in \Lambda} B(p, \eta)} \chi_R |j|^2 + \pi \log \eta \sum_{p \in \Lambda} \chi_R(p).$$

Second, we consider the set $\mathcal{F}_\Lambda$ of vector fields in $L^2_{loc}(\mathbb{R}^2 \setminus \Lambda, \mathbb{R}^2)$ satisfying (1) for a given $\Lambda$ and $m$, and the subset $\mathcal{P}_\Lambda$ of curl-free vector fields in $\mathcal{F}_\Lambda$, or equivalently the set of those elements in $\mathcal{F}_\Lambda$ which are gradients. We may now define

$$W(\Lambda) := \inf_{\nabla U \in \mathcal{P}_\Lambda} W(\nabla U), \quad \tilde{W}(\Lambda) := \inf_{j \in \mathcal{F}_\Lambda} W(j).$$

Note that $\mathcal{F}_\Lambda$ and $\mathcal{P}_\Lambda$ depend on $m$, hence so do $W(\Lambda)$ and $\tilde{W}(\Lambda)$. But in fact (see below) the value of $m$ is determined by $\Lambda$ in the sense that $W(\Lambda)$ or $\tilde{W}(\Lambda)$ can only be finite for at most one value of $m$ (which is the asymptotic density of $\Lambda$ whenever it exists). In any case, the value of $m$ will always be clear from the context or made precise.
Remark 1. It will be useful to generalize somewhat the above definition to allow $j$'s satisfying (1) with

$$\nu := \sum_{p \in \Lambda} \alpha_p \delta_p.$$ 

In this case one should modify the definition of $W(j, \chi_R)$:

$$W(j, \chi_R) := \limsup_{\eta \to 0} \frac{1}{2} \int_{\mathbb{R}^2 \setminus \bigcup_{p \in \Lambda} B(p, \eta)} \chi_R |j|^2 + \pi |\alpha_p|^2 \log \eta \sum_{p \in \Lambda} \chi_R(p).$$

In [5], only $W$ is considered. One could think at first that $W$ and $\tilde{W}$ are equal, the argument being the following: Since $W(j)$ may be seen as the average of $|j|^2$ over $\mathbb{R}^2$ (with the infinite part due to the Dirac masses in (1) removed), then projecting onto the set of curl-free fields would reduce this quantity, so that the infimum of $W(j)$ over $\mathcal{F}_\Lambda$ would in fact be achieved by some $j \in \mathcal{P}_\Lambda$, proving that $W(\Lambda) = \tilde{W}(\Lambda)$. It turns out however that this is not the case and in fact we prove (see Theorem 1 below) that with $m = 0$,

**Theorem.** $W(N) = +\infty$ and $\tilde{W}(N) < +\infty$.

The rest of the paper is devoted to giving sufficient conditions on $\Lambda$ for $\tilde{W}$ and/or $W$ to be finite. There are roughly two factors which can make $W$ or $\tilde{W}$ infinite. First, there is the logarithmic interaction between pairs of points, which can be made infinite by bringing points very close to each other: we will not consider this factor here and to rule it out we restrict ourself to uniform $\Lambda$'s in the following sense.

**Definition 1.** Given a lattice $\Lambda$ and weights $\{\alpha_p\}_{p \in \Lambda}$, we say that $\nu = 2\pi \sum_{p \in \Lambda} \alpha_p \delta_p$ is of uniform type if

$$\min_{p \neq q \in \Lambda} |p - q| > 0, \quad \sup_{p \in \Lambda} |\alpha_p| < \infty.$$ 

If the weights are all equal to 1 we simply say $\Lambda$ is of uniform type.

The second factor which can make $W$ or $\tilde{W}$ infinite is the interaction with the background. If we restrict ourselves to uniform $\Lambda$'s, then for a given $m$ the quantities $W(\Lambda)$ or $\tilde{W}(\Lambda)$ measure how close $\sum_{p \in \Lambda} \delta_p$ is to a uniform density $m$. Our second main result shows that this can be measured by simply counting the number of points of $\Lambda$ in any given ball (see Theorems 2 and 4). In particular we have

**Theorem.** Assume that $\Lambda$ is uniform and that there exists $m, C \geq 0$ and $\varepsilon \in (0, 1)$ such that for any $x \in \mathbb{R}^2$ and $R > 1$ we have, denoting $\sharp E$ the number of elements in $E$,

$$|\sharp (B(x, R) \cap \Lambda) - m \pi R^2| \leq CR^{1-\varepsilon}$$

Then $W(\Lambda) < +\infty$ for this value of $m$.

This criterion for finiteness is optimal in the sense that if we replace the right-hand side in (6) by $CR^{1+\varepsilon}$, then it is not difficult to construct $\Lambda$'s satisfying (6) and having infinite renormalized energies (see Proposition 5). This criterion can be relaxed a bit in the case of $\tilde{W}$ (see Theorem 4).
RENORMALIZED ENERGY

This leaves open the case \( \varepsilon = 0 \) (in which case \( N \) and \( Z \) satisfy (6) with \( m = 0 \)). In this case we are able to prove a partial result (see Theorem 5 for a variant)

**Theorem.** Let \( A \subset \mathbb{Z}^2 \) and \( \Lambda := \mathbb{Z}^2 \setminus A \). Assume there exists some constant \( C > 0 \) such that for all \( x \in \mathbb{R}^2 \) and \( R > 1 \) we have

\[
\sharp (A \cap B(x, R)) \leq CR.
\]

Then \( \tilde{W}(\Lambda) < +\infty \).

The proof of this theorem is based on the fact (see Proposition 6) that under the above hypothesis there exists a bijection between \( \mathbb{Z}^2 \setminus A \) and \( \mathbb{Z}^2 \) under which points are moved at uniformly bounded distances. This is a discrete analogue of a result of G.Strang [10].

The criterion in Theorem 1 is satisfied by perfect (or Bravais) lattices, or more generally by doubly periodic lattices (see [3]) — even though in this case (see below) the conclusion of Theorem 1 is almost trivial. However we are not aware that this is known for quasiperiodic lattices, and thus we give a construction similar to that of Theorem 1 which allows us to conclude for an example of Penrose-type lattice \( \Lambda \) that \( \tilde{W}(\Lambda) < +\infty \). We have not sought generality in this direction, and refer to Section 6 for the construction of \( \Lambda \) and the proof that \( \tilde{W}(\Lambda) \) is finite.

2. SOME PROPERTIES OF \( W, \tilde{W} \)

We always assume the following property of \( \nu := \sum_{p \in \Lambda} \delta_p \), which is satisfied in particular if \( \Lambda \) is uniform.

\[
(7) \quad \limsup_{R \to +\infty} \frac{\nu(B_R)}{|B_R|} < +\infty.
\]

We begin by recalling some facts from [5,6].

**Structure of \( P_\Lambda \):** If \( \Lambda \) satisfies (7) and \( W(\Lambda) \) is finite, then the set \( \{\nabla U \in P_\Lambda \mid W(\nabla U) < +\infty\} \) is a 2-dimensional affine space. Any two gradients in this set differ by a constant vector.

**Minimization:** For any given \( m \), the function \( \Lambda \to W \) defined over the set of \( \Lambda \)'s satisfying (7) is bounded from below and admits a minimizer.

**Scaling:** Denote \( W_m \) the renormalized energy with background \( m \in \mathbb{R} \). If \( j \) satisfies (1) and (7) holds, then

\[
W(j) = m \left( W(j') - \frac{\pi}{2} \log m \right), \quad \text{with} \quad j'(\cdot) = \frac{1}{\sqrt{m}} j \left( \frac{\cdot}{\sqrt{m}} \right).
\]

**Cutoffs:** If (7) holds, then the value of \( W(\Lambda) \) (or \( \tilde{W}(\Lambda) \)) does not depend on the particular choice of cut-off functions \( \chi_R \) as long as they satisfy the stated properties.

**Perfect lattices:** Assume \( \Lambda = \mathbb{Z}\vec{u} \oplus \mathbb{Z}\vec{v} \) where \( (\vec{u}, \vec{v}) \) is a basis of \( \mathbb{R}^2 \) satisfying the normalized volume condition \( |\vec{u} \wedge \vec{v}| = 1 \). Let \( \Lambda^* \) be the dual lattice of \( \Lambda \). Then, taking \( m = 1 \),

\[
W(\Lambda) = \pi \lim_{x \to 0} \left( \sum_{p \in \Lambda^* \setminus \{0\}} \frac{e^{2\pi p \cdot x}}{4\pi^2 |p|^2} + \log |x| \right) - \frac{\pi}{2} \log 2\pi.
\]
Moreover, the minimum of $W$ among lattices of this type is achieved by the triangular lattice

$$
\Lambda_1 := \sqrt{2} \left( (1, 0) \mathbb{Z} \oplus \left( \frac{1}{2} \sqrt{3} \mathbb{Z} \right) \right).
$$

**Uniqueness of $m$:** For a given $\Lambda$, there can be at most one value of $m$ for which $W(\Lambda) < +\infty$. Indeed if $j_1$ (resp. $j_2$) satisfy (1) with $m_1$ (resp. $m_2$) then $-\text{div}(j_1 - j_2) = m_2 - m_1$, and if $m_1 \neq m_2$ this implies that $W(j_1)$ and $W(j_2)$ cannot both be finite. To see this one can use Proposition 1 below in case the points in $\Lambda$ are uniformly spaced. Otherwise one has to resort to the corresponding result in [5].

One of the main points in [5, 6] is the fact that $W$ is bounded below. This is in fact very easy to prove in the case of $\Lambda$’s — or more generally $\nu$’s — which are of uniform type. It is a consequence of the following useful fact.

**Proposition 1.** If $j$ satisfies (1) with $\nu$ of uniform type, then for any $\delta < \frac{1}{2} \inf_{p \neq q \in \Lambda} |p - q|$ there exists $g : \mathbb{R}^2 \to \mathbb{R}$ and $C > 0$ such that

$$
g \geq -C,
$$
such that

$$
g = \frac{1}{2} |j|^2, \quad \text{on} \quad \mathbb{R}^2 \setminus \bigcup_{p \in \Lambda} B(p, \delta),
$$

and such that for any compactly supported lipschitz function $\chi$,

$$
\left| \int_{\mathbb{R}^2} \chi g - W(j, \chi) \right| \leq C N \| \nabla \chi \|_{\infty},
$$

where $N = \# \{ p \in \Lambda | B(p, \delta) \cap \text{Supp} \nabla \chi \neq \emptyset \}$.

**Remark 2.** Note that if we take $\chi$ such that $\chi = 1$ on $B(p, \delta)$ and $\chi = 0$ on every other $B(q, \delta)$ for $q \neq p \in \Lambda$ then (10) implies that $\int_{\mathbb{R}^2} \chi g = W(j, \chi)$. This implies in particular, approximating the indicator function $1_{B(p, \delta)}$ by such functions, that for any $p \in \Lambda$

$$
\int_{B(p, \delta)} g = W(j, 1_{B(p, \delta)}).
$$

**Proof.** In $\mathbb{R}^2 \setminus \bigcup_{p \in \Lambda} B(p, \delta)$, we let $g = \frac{1}{2} |j|^2$. Then, for any $p \in \Lambda$ and any $r \in (0, \delta)$ such that $|j| \in L^2(\partial B(p, r))$ — this is the case for a.e. $r$ — we define $\lambda_{p, r} > 0$ to be a value of $\lambda$ such that

$$
\frac{1}{2} \int_{\partial B(p, r)} \min(|j|^2, \lambda) = \frac{\pi \alpha_p^2}{r} - 2 \alpha_p r m.
$$

The fact that $\lambda_{p, r}$ is well defined follows from the fact that the left-hand side of (12) is a continuous increasing function of $\lambda$ which increases from 0 to (as $\lambda \to +\infty$)

$$
\frac{1}{2} \int_{\partial B(p, r)} |j|^2 \geq \frac{1}{4 \pi r} \left( \int_{\partial B(p, r)} j \cdot \nu \right)^2 = \frac{\pi}{r} (\alpha_p - m \pi r^2)^2 \geq \frac{\pi \alpha_p^2}{r} - 2 \alpha_p m r.
$$

For any $r \leq \delta$ we let, on $\partial B(p, r)$,

$$
g := \frac{1}{2} (|j|^2 - \lambda_{p, r}) + \pi \alpha_p m - \frac{\alpha_p^2}{\delta^2} \log \frac{1}{\delta}.
$$
Then (9) is obviously satisfied, and (8) is satisfied with

\[ C = \left( \sup_{p \in \Lambda} \alpha_p \right)^2 \frac{|\log \delta|}{\delta^2} + \pi|m| \sup_{p \in \Lambda} |\alpha_p|. \]

It remains to prove (10). For any function \( \chi \) and any \( \eta \leq \delta \) we have

\[
\int_{\mathbb{R}^2 \setminus \cup_{p \in \Lambda} B(p, \eta)} \chi \left( \frac{|j|^2}{2} - g \right) = \sum_{p \in \Lambda} \int_{B(p, \delta) \setminus B(p, \eta)} \chi \left( \frac{|j|^2}{2} - g \right).
\]

Then, writing \( A \) for the annulus \( B(p, \delta) \setminus B(p, \eta) \),

\[
\int_A \chi \left( \frac{|j|^2}{2} - g \right) = \chi(p) \int_A \left( \frac{|j|^2}{2} - g \right) + \int_A (\chi - \chi(p)) \left( \frac{|j|^2}{2} - g \right).
\]

We have for any \( r \leq \delta \), on \( \partial B(p, r) \)

\[
\left( \frac{|j|^2}{2} - \frac{1}{2}(|j|^2 - \lambda_{p, r})_+ \right) = \frac{1}{2} \min \left( \frac{|j|^2}{2}, \lambda_{p, r} \right),
\]

hence using (12) we find

\[
\int_A \left( \frac{|j|^2}{2} - g \right) = \int_\eta^\delta \frac{\pi \alpha_p}{r} - 2\pi^2 \alpha_p mr \, dr + \pi(\delta^2 - \eta^2) \left( \pi \alpha_p m + \frac{\alpha_p^2}{\delta^2} \log \frac{1}{\delta} \right) = \pi \alpha_p \log \frac{1}{\eta} - \pi \eta^2 \frac{\alpha_p^2}{\delta^2} \log \frac{1}{\delta}.
\]

On the other hand, since \( |\chi - \chi(p)| \leq r \|\nabla \chi\|_\infty \), and using (12) we have

\[
\left| \int_A (\chi - \chi(p)) \left( \frac{|j|^2}{2} - g \right) \right| \leq \|\nabla \chi\|_\infty \left| \int_\eta^\delta \frac{r}{2} \left( \int_{\partial B(p, r)} \min \left( \frac{|j|^2}{2}, \lambda_{p, r} \right) + Cr \right) \, dr \right| \leq C \|\nabla \chi\|_\infty.
\]

This together with (13), (14) and (15) yields

\[
\lim_{\eta \to 0} \int_{\mathbb{R}^2 \setminus \cup_{p \in \Lambda} B(p, \eta)} \chi \left( g - \frac{|j|^2}{2} \right) - \sum_{p \in \Lambda} \pi \chi(p) \alpha_p^2 \log \eta \leq CN \|\nabla \chi\|_\infty,
\]

where \( N = \sharp \{ p \in \Lambda \mid B(p, \delta) \cap \text{Supp} \nabla \chi \neq \emptyset \} \). This proves (10). \( \square \)

Note that, contrary to the corresponding result in [5], we have not proved that the constant \( C \) in (8) is universal, which is a delicate point. We have included this weaker result for the sake of self-containedness and because it has a simple proof.

3. Examples of finite or infinite energy lattices.

We begin by showing that moving the points in \( \mathbb{Z}^2 \) at a bounded distance yields a lattice \( \Lambda \) with finite energy, assuming \( \Lambda \) is uniform.

**Proposition 2.** Let \( \Lambda \) be a lattice in the plane satisfying \( \inf_{x, y \in \Lambda, x \neq y} |x - y| > 0 \) and let \( \Phi : \Lambda \to \mathbb{Z}^2 \) be a bijective map such that \( \sup_{p \in \Lambda} |\Phi(p) - p| < \infty \). Then \( \mathcal{W}(\Lambda) < +\infty \), with \( m = 1 \).
Proof. Let $R_1 = 2 \sup_{p \in \Lambda} |\Phi(p) - p|$. Then for every $p \in \Lambda$, we solve

\begin{align*}
-\Delta U_p &= 2\pi (\delta_p - \delta_{\Phi(p)}) \quad \text{in } B(p, R_1) \\
\frac{\partial U_p}{\partial \nu} &= 0 \quad \text{on } \partial B(p, R_1)
\end{align*}

where $\nu$ is the outer unit normal on the boundary. Let $V$ be the $\mathbb{Z}^2$-periodic solution — which is unique modulo an additive constant — of

\[-\Delta V = 2\pi \left( \sum_{p \in \mathbb{Z}^2} \delta_p - 1 \right) \quad \text{in } \mathbb{R}^2\]

Then by periodicity $|V(x) + \log |x - p||$ is bounded in $C^2 \left( \cup_{p \in \mathbb{Z}^2} B(p, 1/4) \right)$, while $V(x)$ is bounded in $C^2$ of the complement. More precisely we have the (see for instance [5])

$$V(x) = \sum_{p \in \mathbb{Z}^2 \setminus \{0\}} e^{2\pi p \cdot x} \frac{e^{2\pi p \cdot x}}{2\pi |p|^2}$$

Now we define $j : \mathbb{R}^2 \to \mathbb{R}$ by

$$j = \nabla V + \sum_{p \in \Lambda} \nabla U_p,$$

where $\nabla U_p$ is is extended by 0 outside of $B(p, R_1)$ and thus defined on the whole of $\mathbb{R}^2$.

From the assumptions on $\Lambda$ and $\Phi$ the sum above is finite on any compact set and thus $j$ is well defined and solves

\[-\text{div}(j) = 2\pi \left( \sum_{p \in \Lambda} \delta_p - 1 \right) \quad \text{in } \mathbb{R}^2.\]

On the other hand, $U_p(x) + \log |x - p| - \log |x - \Phi(p)|$ is bounded in $C^2(B(p, R_1))$, uniformly with respect to $p \in \Lambda$. It follows that $j + \nabla \log |x - p|$ is bounded in $B(p, \delta)$ uniformly with respect to $p \in \Lambda$, and $j$ is bounded in $\mathbb{R}^2 \setminus \cup_{p \in \Lambda} B(p, \delta)$, where $\delta > 0$ is half the minimal distance between points of $\Lambda$. A straightforward consequence is that $W(j) < +\infty$ and then $\tilde{W}(\Lambda) < +\infty$. \hfill \square

We will prove below that the conclusion in the above proposition cannot be improved to $W(\Lambda) < +\infty$.

A consequence of Proposition 2 is

**Corollary 1.** We have

$$\tilde{W}(\mathbb{Z}^2 \setminus \mathbb{Z}) < \infty, \quad \tilde{W}(\mathbb{Z}^2 \setminus \mathbb{N}) < \infty$$

**Proof.** We construct a bijective map from $\Phi : \mathbb{Z}^2 \setminus \mathbb{Z} \to \mathbb{Z}^2$ by

$$\Phi(p_1, p_2) = \begin{cases} 
(p_1, p_2 - 1) & \text{if } p_2 \geq 1 \\
(p_1, p_2) & \text{if } p_2 < 0
\end{cases}$$

The desired result follows from the above proposition. The proof for $\mathbb{Z}^2 \setminus \mathbb{N}$ is similar. \hfill \square

A second tool for constructing $j$’s with finite energy is
Proposition 3. Assume \( j_1 \) (resp. \( j_2 \)) satisfy (1) with a \( \nu_1 \) (resp. \( \nu_2 \)) of uniform type. Assume also that \( \nu_1 \) and \( \nu_2 \) satisfy (7) and that \( \nu_1 + \nu_2 \) is of uniform type.

Then, if \( W(j_1) < \infty \) for a background \( m_1 \) and \( W(j_2) < \infty \) for the background \( m_2 \), we have

\[
W(j_1 + j_2) < \infty \quad \text{for the background} \quad m_1 + m_2.
\]

First, we prove two lemmas.

Lemma 1. Assume \( j \) satisfies (1) and (7) with \( \nu \) of uniform type, and assume \( W(j) < \infty \). Then there exists some positive constant \( C \) depending on \( j \) such that for any \( R > 1 \) and \( \delta < \frac{1}{2} \inf \{ |p - q| \mid p \neq q \in \Lambda \} \),

\[
\int_{B_R \setminus \cup_{p \in \Lambda} B(p, \delta)} |j|^2 \leq CR^2, \quad \int_{B_R \cap \cup_{p \in \Lambda} B(p, \delta)} |j - G|^2 \leq CR^2,
\]

where \( G(x) := \alpha_p \frac{x - p}{|x - p|^2} \) if \( x \in B(p, \delta) \) with \( p \in \Lambda \).

Proof. Let \( g \) be constructed in Proposition 1. From (10), we have

\[
\int \chi_{R} g \leq W(j, \chi_{R}) + Cn(R) \leq CR^2,
\]

where \( n(R) := \sharp(\Lambda \cap B_{R+1}) \). Hence

\[
(16) \quad \int \chi_{R} g \leq CR^2.
\]

On the other hand, since \( g \geq -C \) and from the properties of \( \chi_{R} \), we have

\[
(17) \quad \int \chi_{R} g \geq \int_{B_R} g - CR \geq \int_{B_R \setminus \cup_{p \in \Lambda} B(p, \delta)} \frac{1}{2}|j|^2 + \sum_{p \in \Lambda, B(p, \delta) \subset B_R} \int_{B(p, \delta)} g - CR.
\]

For any \( p \in \Lambda \), we define

\[
W(j, 1_{B(p, \delta)}) := \limsup_{\eta \to 0} \frac{1}{2} \int_{B(p, \delta) \setminus B(p, \eta)} |j|^2 + \pi \alpha_p^2 \log \eta
\]

We have, denoting \( A = B(p, \delta) \setminus B(p, \eta) \),

\[
\frac{1}{2} \int_A |j|^2 = \frac{1}{2} \int_A |G|^2 + |j - G|^2 + 2G \cdot (j - G)
\]

\[
= \pi \alpha_p^2 \log \frac{\delta}{\eta} + \frac{1}{2} \int_A |j - G|^2 + \alpha_p \int_\delta^\infty \frac{dr}{r} \int_{\partial B(p, r)} \nu \cdot (j - G)
\]

\[
= \pi \alpha_p^2 \log \frac{\delta}{\eta} + \frac{1}{2} \int_A |j - G|^2 + \alpha_p \int_\delta^\infty \frac{dr}{r} \int_{B(p, r)} \operatorname{div}(j - G)
\]

\[
= \pi \alpha_p^2 \log \frac{\delta}{\eta} + \frac{1}{2} \int_A |j - G|^2 + \pi^2 \alpha_p m(\delta^2 - \eta^2).
\]

Hence, we obtain

\[
(18) \quad W(j, 1_{B(p, \delta)}) = \limsup_{\eta \to 0} \frac{1}{2} \int_A |j|^2 + \pi \alpha_p^2 \log \eta = \pi \alpha_p^2 \log \delta + \frac{1}{2} \int_{B(p, \delta)} |j - G|^2 + \pi^2 \alpha_p m \delta^2
\]
Thus, using (11),

\[ (19) \int_{B(p,\delta)} g = \pi \alpha_p^2 \log \delta + \frac{1}{2} \int_{B(p,\delta)} |j - G|^2 + \pi^2 \alpha_p \beta \delta^2 \]

Gathering (16) to (19), we get

\[ CR^2 \geq \int_{\chi R} g \geq \int_{B_R \cup \cup_{p \in \Lambda} B(p,\delta)} \frac{1}{2} |j|^2 + \sum_{p \in \Lambda : B(p,\delta) \subset B_R} \frac{1}{2} \int_{B(p,\delta)} |j - G|^2 - CR^2. \]

This gives the desired result. \hfill \Box

**Lemma 2.** Assume \( j \) satisfies (1) and (7) with \( \nu \) of uniform type and let \( G \) be the function defined in Lemma 1 — for some \( \delta < \frac{1}{2} \inf \{|p - q| \; | \; p \neq q \in \Lambda \} \) — and extended by 0 on \( \mathbb{R}^2 \setminus \cup_{p \in \Lambda} B(p,\delta) \). Then

\[ W(j) < \infty \Leftrightarrow \limsup_{R \to \infty} \int_{B_R} |j - G|^2 < \infty \]

where \( \int_A \) denotes the average over \( A \).

**Proof.** The “\( \Rightarrow \)” part of the assertion follows from Lemma 1. We prove the reverse implication. We denote by \( g \) the result of applying Proposition 1 to \( j \).

Then from the properties of \( \chi_R \) and using (10), (8),

\[ W(j, \chi_R) \leq \int_{B_R} g \chi_R + CR^2 \leq CR^2 + \int_{B_R \cup \cup_{p \in \Lambda} B(p,\delta)} g + \sum_{p \in \Lambda : B(p,\delta) \subset B_R} \int_{B(p,\delta)} g. \]

Then, as in the proof of Lemma 1,

\[ \int_{B(p,\delta)} g = W(j, 1_{B(p,\delta)}) = \frac{1}{2} \int_{B(p,\delta)} |j - G|^2 + O(1). \]

Using this and (9) we find

\[ W(j, \chi_R) \leq CR^2 + \frac{1}{2} \int_{B_R + \delta} |j - G|^2. \]

This yields the desired result. \hfill \Box

**Proof of Proposition 3.** We denote \( \Lambda_i \) the lattice related to \( j_i \) for \( i = 1, 2 \) and \( \Lambda \) one related to \( j_1 + j_2 \). We write \( \nu_i = \sum_{p \in \Lambda_i} \alpha_{i,p} \delta p, \; i = 1, 2 \). Then we choose

\[ \delta < \frac{1}{2} \min \{ \inf \{|p - q| \; | \; p \neq q \in \Lambda_1 \}, \inf \{|p - q| \; | \; p \neq q \in \Lambda_2 \}, \inf \{|p - q| \; | \; p \neq q \in \Lambda \} \}, \]

and let \( G_i(x) = \alpha_{i,p} \frac{x - p}{|x - p|^2} \) if \( x \in B(p,\delta) \) for \( p \in \Lambda_i \), and \( G_i = 0 \) elsewhere.

Then, under the assumptions of the proposition, there exists \( C > 0 \) such that for any \( R > 0 \)

\[ \int_{B_R} |j_1 - G_1|^2, \; \int_{B_R} |j_2 - G_2|^2 < CR^2. \]

Therefore

\[ \int_{B_R} |j_1 + j_2 - (G_1 + G_2)|^2 < CR^2. \]

In view of the previous Lemma, Proposition 3 is proved. \hfill \Box
Corollary 2. We have, with \( m = 0 \),
\[
\tilde{W}(Z) < +\infty, \tilde{W}(N) < +\infty
\]

Proof. There exists \( j_1 \in \mathcal{F}_Z \) and from Corollary 1 there exists \( j_2 \in \mathcal{F}_{Z^2 \setminus Z} \) such that \( W(j_1) \) and \( W(j_2) \) are both finite with \( m = 1 \). Then, by Proposition 3 and since \(-\text{div}(j_1 - j_2) = \sum_{p \in \mathbb{Z}} \delta_p \), and \( Z \) is uniform, we have \( W(j_1 - j_2) < +\infty \) with \( m = 0 \), hence \( \tilde{W}(Z) < +\infty \).

The proof for \( N \) is identical. \( \square \)

Proposition 4. For \( m = 0 \) we have
\[
W(Z) < +\infty, W(N) = +\infty
\]

The case of \( Z \). We define \( V_1(x) := -\log |\sin(\pi x)| \). Direct calculations lead to
\[
-\Delta V_1 = 2\pi \sum_{p \in \mathbb{Z}} \delta_p \text{ in } \mathbb{R}^2
\]
and
\[
|\nabla V_1(x)| = \pi \frac{|\cos(\pi x)|}{|\sin(\pi x)|}.
\]
Both \( V_1(x) \) and \( |\nabla V_1(x)| \) are 1-periodic functions. Straightforward calculations yield
\[
W(\nabla V_1) < +\infty.
\]

The case of \( N \). We must prove that no \( \nabla U \in \mathcal{P}_N \) is such that \( W(\nabla U) < +\infty \). Our strategy is to construct \( \nabla H_1 \in \mathcal{P}_N \) such that \( W(\nabla H_1) = +\infty \), and such that \( W(\nabla H_1, \chi_R) < CR^2 \log^2 R \). Then, if there existed \( \nabla H_2 \in \mathcal{P}_N \) such that \( W(\nabla H_2) < +\infty \), we would conclude that \( W(\nabla (H_1 - H_2), \chi_R) \) grows at most like \( R^2 \log^2 R \). Since \( H_1 - H_2 \) is harmonic we conclude from a Liouville type theorem that \( \nabla (H_1 - H_2) \) is constant, which contradicts \( W(\nabla H_1) = +\infty \).

To construct \( H_1 \) we use the Weierstass construction for a holomorphic function in the plane with a simple zero at each \( p \in \mathbb{N} \) to define
\[
H(x) := \Pi_{k \in \mathbb{N}} (1 - \frac{x}{k}) e^{\bar{x}}.
\]
Then we let
\[
H_1(x) = -\log |H(x)|.
\]
It is straightforward to check that the product in the definition of \( H \) converges uniformly on any compact subset of \( \mathbb{C} \) and that
\[
-\Delta H_1 = 2\pi \sum_{k \in \mathbb{N}} \delta_k \text{ in } \mathbb{R}^2
\]
and for all \( x \in \mathbb{C} = \mathbb{R}^2 \)
\[
|H_1(x)| \leq \sum_{k \in \mathbb{N}} \left| \log \left( 1 - \frac{x}{k} \right) + \frac{x}{k} \right|
\]
and
\[
|\nabla H_1(x)| = \left| \sum_{k \in \mathbb{N}} \frac{x}{k(k-x)} \right|.
\]
Next, rather than proving $W(\nabla H_1, \chi_R) < CR^2 \log^2 R$, we prove the stronger, pointwise estimates:

(22) \[ |\nabla H_1(x)| \leq C(\log(|x|+1)+1), \text{ outside } \bigcup_{k\in\mathbb{N}} B(k, \frac{1}{4}), \]

(23) \[ \left| \nabla H_1(x) + \frac{1}{x-k} \right| \leq C(\log(|x|+1)+1), \text{ in } B(k, \frac{1}{4}). \]

For (22), take any $x \in \mathbb{C} \setminus \bigcup_{k\in\mathbb{N}} B(k, \frac{1}{4})$, it follows from (21) that

\[ |\nabla H_1(x)| \leq \sum_{1 \leq k \leq \lfloor 2|x|+1 \rfloor} \left( \frac{1}{k-x} + \frac{1}{k} \right) + \sum_{k > \lfloor 2|x|+1 \rfloor} \left| \frac{x}{k(k-x)} \right| := I + II, \]

where $\lfloor \cdot \rfloor$ denotes the integer part of a real number. We have

\[ II \leq \sum_{k > \lfloor 2|x|+1 \rfloor} \frac{|x|}{(k-|x|)^2} \leq |x| \int_{|x|}^{+\infty} \frac{dt}{t^2} \leq 1, \]

\[ \sum_{1 \leq k \leq \lfloor 2|x|+1 \rfloor} \frac{1}{k} \leq 2 \log((|x|+1)+1). \]

On the other hand,

\[ \sum_{1 \leq k \leq \lfloor 2|x|+1 \rfloor} \left| \frac{1}{k-x} \right| \leq \sum_{1 \leq k \leq \lfloor 2|x|+1 \rfloor} \left| \frac{1}{\Re(k-x)} \right| \leq 5 + 2 \int_{1}^{2|x|+1} \frac{dt}{t} \leq 5 \log(|x|+1)+1. \]

Therefore, for any $x \in \mathbb{C} \setminus \bigcup_{k\in\mathbb{N}} B(k, \frac{1}{4})$, we have $|\nabla H_1(x)| \leq 8(\log(|x|+1)+1)$, and therefore (22) holds.

Now we prove (23). Let $x \in B(k, \frac{1}{4})$ for some $k \in \mathbb{N}$. As above

\[ \left| \nabla H_1(x) + \frac{\Re(x) - k}{|x-k|^2} - \frac{\Im(x)}{|x-k|^2} \right| \leq 8(\log(|x|+1)+1) + \frac{1}{k} \leq 9(\log(|x|+1)+1), \]

or equivalently, if we use the division of complex number,

\[ \left| \nabla H_1(x) + \frac{1}{x-k} \right| \leq 8(\log(|x|+1)+1) + \frac{1}{k} \leq 9(\log(|x|+1)+1), \]

since $x \in \mathbb{C} \setminus \bigcup_{i\neq k\in\mathbb{N}} B(i, \frac{1}{4})$. This proves (23).

We now turn to the proof that $W(\nabla H_1) = +\infty$. This is done by computing a lower bound for $|\nabla H_1(x)|$. More precisely we prove that or any $\epsilon > 0$, there exists some positive constant $C_1$ depending on $\epsilon$ such that

(24) \[ |\nabla H_1(x)| \geq (\log(|x|+1) - C_1), \quad \text{if } |\Im(x)| \geq \epsilon |x| + 1. \]

For this purpose we consider the meromorphic function

\[ f(x) := \sum_{k \in \mathbb{N}} \frac{x}{k(k-x)}. \]
If $|\Im(x)| \geq \varepsilon |x| + 1$, then $x \in \mathbb{C} \setminus \cup_{k \in \mathbb{N}} B(k, \frac{1}{4})$. Thus

$$
\left| f(x) - \sum_{1 \leq k \leq [2|x|+1]} \left( \frac{1}{k} - x \right) \right| \leq 2 |x| \leq 1,
$$

so that

$$
\left| f(x) + \sum_{1 \leq k \leq [2|x|+1]} \frac{1}{k} \right| \leq 1 + \sum_{1 \leq k \leq [2|x|+1]} \left| \frac{1}{k - x} \right|
\leq 1 + \sum_{1 \leq k \leq [2|x|+1]} \frac{|\Im(x)|}{|\Im(x)|}
\leq 1 + \frac{2|2x|+1}{|\Im(x)|}
\leq 1 + 2/\varepsilon.
$$

On the other hand, we have

$$
\sum_{1 \leq k \leq [2|x|+1]} \frac{1}{k} \geq \log(|x| + 1),
$$

hence (24) follows. We claim that this implies that $W(\nabla H_1) = +\infty$.

To see this, we need to bound from below the integral of $\chi_{\mathbb{R}}|\nabla H_1|^2$. We define $g$ by applying Proposition 1 to $\nabla H_1$ with $\delta = 1/4$. Then we deduce from (8), (9) and the fact that $\chi_\mathbb{R} = 1$ on $B_{R-1}$ that

$$
\int \chi_\mathbb{R}|\nabla H_1|^2 \geq \int_{B_{R-1}} |\nabla H_1|^2 - CR.
$$

Then, integrating (24) on $\{x \in B_{R-1} \mid |\Im(x)| \geq \varepsilon |x| + 1\}$ proves that $W(\nabla H_1) = +\infty$.

We may now argue by contradiction to prove the proposition. Assume that there exists $H_2 \in \mathcal{P}_\mathbb{N}$ such that $W(\nabla H_2) < +\infty$. Then $H = H_2 - H_1$ is a harmonic function over $\mathbb{R}^2$.

For $i = 1, 2$, we define $g_i$ by applying Proposition 1 to $\nabla H_i$ with $\delta = 1/4$. Then

$$
CR^2 \geq W(\nabla H_2, \chi_\mathbb{R}) - W(\nabla H_1, \chi_\mathbb{R}) \geq \int \chi_\mathbb{R}(g_2 - g_1) - CR \geq \int_{B_{R-1}} (g_2 - g_1) - CR.
$$

Then, letting $G(x) = (x-k)/|x-k|^2$ in $B(k, 1/4)$ for every $k$ and $G = 0$ outside $\cup_k B(k, 1/4)$ we have, as in (19), for every $k$

$$
\int_{B(k, 1/4)} g_i = \int_{B(k, 1/4)} \frac{1}{2} |\nabla H_i - G|^2 + C_0,
$$

where $C_0 = -\pi \log 4$. Together with (9), this implies that

$$
\int_{B_{R-1}} (g_2 - g_1) \geq \frac{1}{2} \int_{B_{R-1}} \frac{1}{2} |\nabla H_2|^2 - |\nabla H_1|^2 - \frac{1}{2} \sum_{k=0}^{[R]} \int_{B(k, 1/4)} \frac{1}{2} |\nabla H_1 - G|^2 - CR.
$$
Using (23) we have
\[ \int_{B(k,1/4)} \frac{1}{2} |\nabla H_1 - G|^2 \leq C (\log (k + 1) + 1)^2, \]
so that
\[ CR^2 \geq \frac{1}{2} \int_{B_{R-1} \setminus \cup_k B(k,1/4)} (|\nabla H_2|^2 - |\nabla H_1|^2) - CR \log^2 R. \]
Then, writing
\[ |\nabla H_2|^2 - |\nabla H_1|^2 = |\nabla \tilde{H}|^2 + 2 \nabla \tilde{H} \cdot \nabla H_1, \]
we find using (22) that on \( B_{R-1} \setminus \cup_k B(k,1/4) \)
\[ |\nabla H_2|^2 - |\nabla H_1|^2 \geq |\nabla \tilde{H}|^2 - C \log R |\nabla \tilde{H}|, \]
and thus, letting \( A_R = B_{R-1} \setminus \cup_k B(k,1/4), \)
\[ CR^2 \geq \frac{1}{2} \int_{A_R} (|\nabla \tilde{H}|^2 - C \log R |\nabla \tilde{H}|) - CR \log^2 R, \]
from which we easily deduce
\[ \int_{A_R} |\nabla \tilde{H}|^2 \leq CR^2 \log^2 R. \]
It follows by a mean value argument that there exists \( t \in [R/2, R - 1] \) such that
\[ \int_{\partial B_t} |\nabla \tilde{H}|^2 \leq CR \log^2 R, \]
and since \( \tilde{H} \) is harmonic, for any \( x \in B_{R/4} \) we have
\[ |\nabla^2 \tilde{H}(x)| \leq \frac{1}{R^2} \int_{\partial B_t} |\nabla \tilde{H}| \leq C \frac{1}{R^2} \sqrt{R} R \log R. \]
Fixing \( x \) and letting \( R \to \infty \), we find \( \nabla^2 \tilde{H}(x) = 0 \). Therefore \( \nabla \tilde{H} \) is a constant, which is clearly not possible since \( W'(\nabla H_1) = +\infty \) while \( W'(\nabla H_1 + \nabla \tilde{H}) < +\infty \). \( \square \)

We summarize the content of this section in the following

**Theorem 1.** We have

\begin{align*}
(25) \quad \tilde{W}(Z) &< +\infty, \quad \tilde{W}(N) < +\infty, \quad \tilde{W}(Z^2 \setminus Z) < +\infty, \quad \tilde{W}(Z^2 \setminus N) < +\infty \\
(26) \quad W(Z) &< +\infty, \quad W(Z^2) < +\infty, \quad W(Z^2 \setminus Z) < +\infty \\
(27) \quad W(N) &< +\infty, \quad W(Z^2 \setminus N) = +\infty 
\end{align*}

**Proof.** The result comes from Corollary 1, Corollary 2, Proposition 3 and Proposition 4. \( \square \)
4. Sufficient conditions for finite renormalized energy

**Theorem 2.** Given a discrete lattice \( \Lambda \), assume there exists \( m \geq 0 \) and \( \varepsilon \in (0, 1) \), \( C > 0 \) such that for any \( x \in \mathbb{R}^2 \) and for \( R > 1 \), we have

\[
\left\| \sum (B(x, R) \cap \Lambda) - m\pi R^2 \right\| \leq CR^{1-\varepsilon}
\]

and

\[
\inf_{x, y \in \Lambda, x \neq y} |x - y| > 0
\]

Then \( W(\Lambda) < +\infty \).

**Remark 3.** For a Bravais lattice, the assumptions in the above theorem are satisfied. It was proved by Landau (1915) — see [3] for a more general statement — that the first assumption holds with \( \varepsilon = 1/3 \), see [2] for references on more recent developments.

We recall a technical lemma.

**Lemma 3.** (Theorem 8.17 in [1]) Assume \( q > 2 \) and \( p > 1 \) and \( v \) is a solution of the following equation

\[
-\Delta u = g + \sum_i \partial_i f_i
\]

there exists some constant \( C \) such that

\[
\|u\|_{L^\infty(B(0, R))} \leq C(R^{-\frac{2}{q}} \|u\|_{L^p(B(0, 2R))} + C^{-\frac{1}{2}} \|f\|_{L^q(B(0, 2R))} + R^{2-\frac{2}{q}} \|g\|_{L^{q/2}(B(0, 2R))})
\]

**Proof of Theorem 2.** Assume \( \Lambda \) satisfies (28) and (29). The proof consists in constructing \( j \in F_\Lambda \) such that \( W(j) < +\infty \), which is done by successive approximations constructing a first some \( U_1 \), then a correction \( U_2 \) to \( U_1 \), then a correction \( U_3 \) to \( U_1 + U_2 \), etc... In this construction, the \( U_k \)'s are functions, and the sum of their gradients will converge to \( j \).

Let \( R_n = 2^{n-1} \). For all \( p \in \Lambda \), we let \( U_{p 1} \) be the solution to

\[
\begin{cases}
-\Delta U_{p 1}(y) & = 2\pi \left( \delta_p(y) - \frac{1_{B(p, R_1)}(y)}{\pi R_1^2} \right) \quad \text{in } B(p, R_1) \\
U_{p 1}(y) & = \frac{\partial U_{p 1}}{\partial \nu}(y) = 0 \quad \text{on } \partial B(p, R_1)
\end{cases}
\]

where \( 1_{B(x, r)} \) is the indicator function of the ball \( B(x, r) \). The existence of a solution with Neumann boundary conditions follows from the fact that \( \delta_p - \frac{1_{B(p, R_1)}}{\pi R_1^2} \) has zero integral, and the radial symmetry of the solution implies \( U_{p 1} \) is constant on the boundary, and the constant can be taken equal to zero. In fact, extending \( U_{p 1} \) by zero outside \( B(p, R_1) \), we get a solution of

\[
-\Delta U_{p 1}(y) = 2\pi \left( \delta_p(y) - \frac{1_{B(p, R_1)}(y)}{\pi R_1^2} \right)
\]

in \( \mathbb{R}^2 \), which is supported in \( B(p, R_1) \).

We let

\[
U_1(y) := \sum_{p \in \Lambda} U_{p 1}(y).
\]
This sum is well defined since, \( \Lambda \) being discrete, it is locally finite. Moreover \( U^1 \) solves
\[
- \Delta U^1(y) = 2\pi \left( \sum_{p \in \Lambda} \delta_p - n_1(y) \right), \quad \text{where} \quad n_1(y) := \frac{\#(\Lambda \cap B(y, R_1))}{\pi R_1^2}.
\]

Then we proceed by induction. For any \( k \geq 2 \) we let \( U^k \) be the solution to
\[
\begin{cases}
- \Delta U^k_p(y) = 2\pi \left( \frac{1_{B(p, R_{k-1})}(y)}{\pi R_{k-1}^2} - \frac{1_{B(p, R_k)}(y)}{\pi R_k^2} \right) \quad \text{in} \quad B(p, R_k) \\
U^k_p(y) = \frac{\partial U^k_p}{\partial n}(y) = 0 \quad \text{on} \quad \partial B(p, R_k),
\end{cases}
\]
and we let \( U^k_p = 0 \) outside the \( B(p, R_k) \). We let \( U^k(y) := \sum_{p \in \Lambda} U^k_p(y) \), so that
\[
- \Delta U^k(y) = 2\pi \left( n_{k-1}(y) - n_k(y) \right),
\]
where, for any \( k \in \mathbb{N} \),
\[
n_k(y) := \frac{\#(\Lambda \cap B(y, R_k))}{\pi R_k^2}.
\]

Now we study the convergence of \( \sum_{k=1}^{\infty} \nabla U^k \).

First we note that there is an explicit formula for \( U^k_p \). For any \( k \geq 2 \) we have
\[
U^k_p(y) = V \left( \frac{y - p}{R_k} \right), \quad \text{where} \quad V(y) := \begin{cases} \frac{3|y|^2}{2} + \ln 2 & \text{if } |y| \leq \frac{1}{2} \\ \frac{|y|^2}{2} - \ln |y| - \frac{1}{2} & \text{if } \frac{1}{2} < |y| \leq 1 \\ 0 & \text{if } |y| \geq 1, \end{cases}
\]
from which it follows, since \( \|\nabla U^k_p\|_\infty \leq \frac{C}{R_k} \) and the sum defining \( U^k \) has at most \( CR_k^2 \) non-zero terms, that
\[
\|\nabla U^k\|_\infty \leq CR_k.
\]

Second we estimate \( \|U^k\|_\infty \). We claim that
\[
\forall k \geq 2, \exists C_k \in \mathbb{R} \text{ such that } \|U^k(y) - C_k\|_\infty = O(R_k^{1-\varepsilon}).
\]
Indeed, from (28),
\[
n_k - m\|_\infty \leq CR_k^{-1-\varepsilon}.
\]
On the other hand, letting \( n_y(r) := \#(B(y, r) \cap \Lambda) \), we have for any \( y \not\in \Lambda \)
\[
U^k(y) = \sum_{p \in B(y, R_k) \cap \Lambda} V \left( \frac{|p - y|}{R_k} \right) = \int_0^{R_k} V \left( \frac{t}{R_k} \right) n'_y(t) dt = - \int_0^{R_k} \frac{1}{R_k} V' \left( \frac{t}{R_k} \right) n_y(t) dt.
\]
But, using (28), we have \( n_y(t) = m \pi t^2 + O(t^{1-\varepsilon}) \), hence
\[
U^k(y) = -m \pi \int_0^{R_k} \frac{1}{R_k} V' \left( \frac{t}{R_k} \right) t^2 dt + O(R_k^{1-\varepsilon}).
\]
The first term is independent of \( y \), we call it \( C_k \). This proves (33).

Finally, we note that, from (34), it holds that
\[
\|\Delta U^k\|_\infty = O(R_k^{1-\varepsilon}).
\]
Now, we claim that (33) and (35) imply that
\[ \| \nabla U^k \|_\infty = O(R_k^{-\varepsilon}) \]
To see this we use the elliptic estimate of Lemma 3. For all \( y \in \mathbb{R}^2 \) we have
\[ \int_{B(y, R_k)} |\nabla U^k|^2 = \int_{B(y, R_k)} |(U^k - C_k)|^2 \]
\[ = - \int_{B(y, R_k)} \Delta U^k (U^k - C_k) + \int_{\partial B(y, R_k)} \frac{\partial U^k}{\partial \nu} (U^k - C_k) \leq CR_k^2 \left( R_k^{\varepsilon} + \| \nabla U^k \|_\infty R_k^{-\varepsilon} \right) \]
Now we apply Lemma 3. For \( i = 1, 2 \) we have
\[ \Delta (\partial_i U^k) = -2\pi \partial_i (n_{k-1} - n_k), \]
therefore for any \( q > 2 \) and \( p > 1 \),
\[ \| \partial_i U^k \|_{L^\infty(B_{Rk}/2)} \leq C \left( R_k^{-\varepsilon} \| \partial_i U^k \|_{L^p(B_{Rk})} + R_k^{\varepsilon} \| n_{k-1} - n_k \|_{L^q(B_{Rk})} \right) \]
Then, taking \( p = 2 \) and noting that (34) implies \( \| n_{k-1} - n_k \|_q \leq CR_k^{\varepsilon - (1+\varepsilon)} \), we find using (37) that
\[ \| \partial_i U^k \|_{L^\infty(B_{Rk}/2)} \leq C \left( R_k^{-2\varepsilon} + R_k^{-\varepsilon} \| \nabla U^k \|_{L^\infty(B_{Rk})} \right)^{\frac{1}{2}} + CR_k^{-\varepsilon}. \]
This proves (36).
Now (36) implies that the sum \( \sum_{k \geq 2} \nabla U^k \) converges, and if we let \( j = \nabla U_1 + \sum_{k \geq 2} \nabla U^k \), then \( -\text{div} j = 2\pi (\sum_{p \in \Lambda} \delta_p - m) \), using (30), (31) and (34). Moreover \( j \) is a gradient since it is a sum of gradients, thus \( j \in P_{\Lambda} \).
To conclude, it is easy to check, using the assumption \( \inf_{x,y \in \Lambda, x \neq y} |x - y| > 0 \), that \( W(\nabla U^1, \chi_R) \leq CR^2 \) for all \( R > 1 \), and to deduce using (36) that \( W(j, \chi_R) \leq CR^2 \). \( \square \)

For \( \tilde{W} \) the hypothesis of Theorem 2 can be relaxed somewhat.

**Theorem 2'.** Assume there exists some non-negative number \( m \geq 0 \) and some positive numbers \( \varepsilon \in (0, 1) \), \( C > 0 \) and a increasing sequence \( \{ R_n \} \) tending to \( +\infty \) such that for any \( x \in \mathbb{R}^2 \) and for any \( n \in \mathbb{N} \), we have
\[ |B(x, R_n) \cap \Lambda| - m\pi R_n^2 \leq CR_n^{1-\varepsilon}, \]
and such that
\[ \sum_n R_n^{-\varepsilon} < +\infty \]
and
\[ \inf_{x,y \in \Lambda, x \neq y} |x - y| > 0. \]
Then \( \tilde{W}(\Lambda) < +\infty \).

We will use the following simple estimate.
Lemma 4. Let \( u \) be a solution of the following problem
\[
\begin{align*}
-\Delta u &= f \quad \text{in } \Omega \\
\frac{\partial u}{\partial \nu} &= 0 \quad \text{on } \partial \Omega
\end{align*}
\]
Then
\[
\int_{\Omega} |\nabla u|^2 \leq C |\Omega|^2 \|f\|_\infty^2
\]
where \( C \) is a constant independent of \( \Omega \).

Proof. We have
\[
\int_{\Omega} |\nabla u|^2 = -\int_{\Omega} u \Delta u = \int_{\Omega} fu \leq \|u\|_1 \|f\|_\infty \leq \sqrt{|\Omega|} \|u\|_2 \|f\|_\infty
\]
Without loss of generality, we assume \( \int u = 0 \). By Poincaré inequality,
\[
\|u\|_2 \leq C \sqrt{|\Omega|} \|\nabla u\|_2
\]
Finally, the desired result follows. \( \square \)

Proof of Theorem 2'. Let
\[
\mu_{\Lambda} = \sum_{p \in \Lambda} \delta_p, \quad I_k = \frac{1_{B_{R_k}}}{|B_{R_k}|},
\]
for any integer \( k > 0 \), where \( 1_{B_{R_k}} \) is the indicator function of the ball \( B(0, R_k) \).

At the first step, for all \( x \in \mathbb{R}^2 \) we let \( U_1^1 \) be the solution to
\[
\begin{align*}
-\Delta U_1^1(y) &= 2\pi \left( \mu_{\Lambda}(y) - \mu_{\Lambda} * I_1(x) \right) 1_{B_{R_1}}(x - y) \quad \text{in } B(x, R_1 + 1) \\
\frac{\partial U_1^1}{\partial \nu}(y) &= 0 \quad \text{on } \partial B(x, R_1 + 1).
\end{align*}
\]
This equation has a solution which is unique up to an additive constant since
\[
\int \left( \mu_{\Lambda}(y) - \mu_{\Lambda} * I_1(x) \right) 1_{B_{R_1}}(x - y) dy = \mu_{\Lambda} * (\pi R_1^2 I_1)(x) - \pi R_1^2 \mu_{\Lambda} * I_1(x) = 0.
\]
We extend \( \nabla U^1 \) by zero outside \( B(x, R_1 + 1) \) and let
\[
j^1(y) := \frac{1}{\pi R_1^2} \int_{\mathbb{R}^2} \nabla U^1_x(y) dx,
\]
so that
\[
-\text{div}(j^1) = 2\pi \left( \sum_{p \in \Lambda} \delta_p - m_1(y) \right), \quad \text{where } m_1 = \mu_{\Lambda} * I_1 * I_1.
\]

Then we define \( j^k \) by induction. For \( x \in \mathbb{R}^2 \) we let \( U^k_x \) be the solution to
\[
\begin{align*}
-\Delta U^k_x(y) &= 2\pi \left( m_{k-1}(y) - m_{k-1} * I_k(x) \right) 1_{B_{R_k}}(x - y) \quad \text{in } B(x, R_k + 1) \\
\frac{\partial U^k_x}{\partial \nu}(y) &= 0 \quad \text{on } \partial B(x, R_k + 1),
\end{align*}
\]
and extend \( \nabla U^k_x \) by 0 outside the ball \( B(x, R_k) \). Then we let
\[
j^k(y) := \frac{1}{\pi R_k^2} \int_{\mathbb{R}^2} \nabla U^k_x(y) dx.
\]
so that

$$- \text{div}(j^k)(y) = 2\pi (m_{k-1}(y) - m_k(y)), \quad \text{where} \quad m_k = m_{k-1} \ast I_k \ast I_k.$$  

We claim that

$$m_k(y) = m + O(R_k^{-1-\varepsilon}). \tag{38}$$  

To see this, it suffices to note that from the commutativity of the convolution we have

$$m_k = (\mu_k \ast I_k) \ast (I_k \ast I_{k-1} \ast I_{k-1} \ast \cdots \ast I_1 \ast I_1).$$

Then from our first assumption $|\mu_k \ast I_k - m| \leq C R_k^{-(1+\varepsilon)}$, which implies (38) since every $I_k$ is a positive function with integral 1, and thus convoluting a function with it does not increase the $L^\infty$ norm.

It follows from Lemmas 3 and 4 that for all $k \geq 2$ and $x \in \mathbb{R}^2$

$$\|\nabla U_x\|_{L^\infty(\mathbb{R}^2)} \leq C R_k^{-1-\varepsilon},$$

which yields for all $k \geq 2$

$$\|j^k\|_{L^\infty(\mathbb{R}^2)} \leq C R_k^{-1-\varepsilon}.$$  

Therefore $\sum_{k \geq 2} \|j^k\|_\infty \leq +\infty$ and we can define $j := \sum_{k \geq 1} j^k$. The vector field $j$ solves

$$- \text{div}(j) = 2\pi \left( \sum_{p \in \Lambda} \delta_p - m \right) \quad \text{in} \quad \mathbb{R}^2.$$  

Now it suffices to prove that $W(j) < +\infty$. This is clearly a consequence of the fact that $W(j_1) < +\infty$ and the fact that $\sum_{k \geq 2} \|j^k\|_\infty \leq +\infty$. On the other hand, $W(j_1) < +\infty$ is proved as follows: For any $p \in \Lambda$, and any $x \in B(p, R_1)$ we have $\|U_x^1(y) - \log|y - p|\| < C$ in $C^1(B(p, \delta))$ with $C, \delta > 0$ independent of $p, x$ and $y$, because of the equation satisfied by $U^1_\lambda$ and the uniform spacing of the points in $\Lambda$. Also, if $x \notin B(p, R_1)$, then $\|U_x^1(y)\| < C$ in $C^1(B(p, \delta))$.

Then, since $j_1^1 = \int \nabla U_x^1/\pi R_1^2$, we have $|j_1^1(y) - \log|y - p|| < C$ in $B(p, \delta)$ for any $p \in \Lambda$ and $|j_1^1| < C$ outside $\cup_{p \in \Lambda} B(p, \delta)$. This implies that $W(j_1) < +\infty$.  

**Proposition 5.** The conditions in Theorem 3 are optimal in some sense. More precisely, for any $m \geq 0$ and any $\varepsilon > 0$ there exists $\Lambda$ such that $W(\Lambda) = +\infty$ and for any $x \in \mathbb{R}^2$ and any $R > 1$

$$\sharp \left( B(x, R) \cap \Lambda \right) - m\pi R^2 \geq CR^{1+\varepsilon}.$$  

**Proof.** The counter-example is as follows, assuming without loss of generality that $\varepsilon < 1/2$: For all $k \in \mathbb{N}$, on the circle $\partial B(0, 4k)$, we distribute uniformly $[32\pi mk + k^\varepsilon]$ points, where $[x]$ is the integer part of $x$. This is clearly possible maintaining at the same time a distance greater than $\min(1/5m, 1)$ (if $k$ is large enough) between the points, since $k^\varepsilon \ll k$ as $k \to +\infty$.

Then we have as $k \to +\infty$

$$\sharp \left( \Lambda \cap B(0, 4k) \right) - m\pi(4k)^2 \simeq \sum_{i=1}^{k-1} [i^\varepsilon] \simeq \frac{k^{1+\varepsilon}}{1+\varepsilon},$$
thus for any $j$ such that
\[-\text{div}(j) = 2\pi \left( \sum_{p \in \Lambda} \delta_p - m \right),\]
and for any $R \in (4k + 1, 4k + 3)$, we have
\[
\int_{\partial B(0,R)} j \cdot \nu = 2\pi \left( \sharp(\Lambda \cap B(0,R)) - m\pi R^2 \right) \simeq \frac{2\pi}{1+\epsilon} k^{1+\epsilon}.
\]
Thus there exist $k_0 > 0$, $c_0 > 0$ such that if $k > k_0$ and for any $R \in (4k + 1, 4k + 3)$, we have
\[
\int_{\partial B(0,R)} |j|^2 \geq \frac{1}{4\pi R} \left( \int_{\partial B(0,R)} j \cdot \nu \right)^2 \geq c_0 k^{1+2\epsilon}
\]
Now we construct $g$ using proposition 1 with $\delta < \frac{\inf_{p \neq q \in \Lambda} |p - q|}{2}$ and $\delta < 1$. For functions $\{\chi_R\}_R$ satisfying (2), we have for any $k \in \mathbb{N}$ and since the support of $\chi_{4k+2}$ does not intersect $\bigcup_{p \in \Lambda} B(p, \delta)$ that
\[
W(j, \chi_{4k+2}) = \int g\chi_{4k+2} = \int_{\bigcup_{p \in \Lambda} B(p, \delta)} g\chi_{4k+2} + \int_{\mathbb{R}^2 \setminus \bigcup_{p \in \Lambda} B(p, \delta)} g\chi_{4k+2}
\]
and therefore, since $g = \frac{1}{2} |j|^2$ outside $\bigcup_{p \in \Lambda} B(p, \delta)$ and $g \geq -C$, we obtain
\[
W(j, \chi_{4k+2}) \geq \sum_{i \leq k-1} \int_{B(0,4i+1) \setminus B(0,4i+3)} |j|^2 - CR^2 \geq CR^{2+2\epsilon},
\]
where we used (39) for the last inequality. Therefore $W(j) = +\infty$. \hfill \qed

5. Critical case

In view of Theorem 2 and Proposition 5, the critical discrepancy between $\sum_{p \in \Lambda} \delta_p$ and the uniform measure $m dx$ is when $\left| \sharp (B(x, R) \cap \Lambda) - m \pi R^2 \right| = O(R)$. This includes the cases $\Lambda = \mathbb{Z}$ or $\mathbb{N}$. As shown by Theorem 1, we cannot expect $W(\Lambda)$ to be finite under such an assumption. However we have the following result for $\tilde{W}$.

**Theorem 3.** Let $A \subset \mathbb{Z}^2$ and $\Lambda := \mathbb{Z}^2 \setminus A$. Assume there exists some constant $C > 0$ such that for all $x \in \mathbb{R}^2$ and for all $R > 1$ we have
\[
\sharp (A \cap B(x, R)) \leq CR.
\]

Then
\[
\tilde{W}(\Lambda) < +\infty
\]
This result is a direct consequence of Proposition 2 and the following:

**Proposition 6.** Let $A \subset \mathbb{Z}^2$. Then the following properties are equivalent.

**Property I:** There exists some constant $C > 0$ such that for all $x \in \mathbb{R}^2$ and for all $R > 1$ we have
\[
\sharp (A \cap B(x, R)) \leq CR
\]
Property II.: There exists a bijective map $\Phi : \Lambda \to \mathbb{Z}^2$ satisfying
\begin{equation}
\sup_{p \in \Lambda} |\Phi(p) - p| < \infty
\end{equation}

The fact that the second property implies the first one is not difficult. First note that \begin{equation}
\text{(41)}
\end{equation} is equivalent to the same property for $\Phi^{-1}$, and that Property I is equivalent to the same property with squares $K_R$ of sidelength $R$ replacing the balls of radius $R$.

Now assume $\sharp(A \cap K_R) > CR$, then $\Phi^{-1}(K_R \cap \mathbb{Z}^2)$ is included in $\mathbb{Z}^2 \setminus A$ and thus contains at least $CR$ points which do not belong to $K_R$. Therefore, as $C \to +\infty$, the maximal distance between an element $p$ of $\Phi^{-1}(K_R \cap \mathbb{Z}^2)$ and $K_R$ tends to $+\infty$. This proves that $\Pi \implies I$.

The proof of the converse is less obvious. It is essentially an application of the max-flow/min-cut duality, with arguments similar in spirit to those found in \cite{10}.

We let $G$ be a graph for which the set of vertices is $\mathbb{Z}^2$ and the set of edges is
\begin{equation}
\mathcal{A} := \{ (p,q) \mid p,q \in \mathbb{Z}^2, \|p-q\| = 1 \}
\end{equation}
where $\| \cdot \|$ is the Euclidean norm. Given an integer $N \in \mathbb{N}$, we define some function
\begin{equation}
\mu_N : \mathbb{Z}^2 \to \mathbb{R}_+ \qquad p \mapsto N^2 - \sharp(\Lambda \cap K_p^N)
\end{equation}
where $K_p^N := [kN, (k+1)N) \times [lN, (l+1)N)$ for $p = (k,l)$. Since $\Lambda = \mathbb{Z}^2 \setminus A$, $\mu_N$ is indeed non-negative and $\mu_N(p)$ is equal to $\sharp(A \cap K_p^N)$, i.e. the deficit of the points of $\Lambda$ in $K_p^N$.

We introduce the following notions.

- A flow, or 1-form is a map $\varphi : \mathcal{A} \to \mathbb{R}$ such that for any edge $(p,q)$ one has $\varphi(p,q) = -\varphi(q,p)$.
- Given a flow $\varphi$, its divergence $\text{div}(\varphi)$ is the function $\text{div}(\varphi) : \mathbb{Z}^2 \to \mathbb{R}$ such that for any $p \in \mathbb{Z}^2$ one has
\begin{equation}
\text{div}(\varphi)(p) := \sum_{(p,q) \in \mathcal{A}} \varphi(p,q)
\end{equation}
- Given a function $f : \mathbb{Z}^2 \to \mathbb{R}$, its gradient $\nabla f$ is the 1-form $\nabla f(p,q) = f(q) - f(p)$.
- Given a subset $A$ of $\mathbb{Z}^2$, its boundary $\partial A$ is defined by
\begin{equation}
\partial A := \{ (p,q) \in \mathcal{A} \mid p \in A, q \in \mathbb{Z}^2 \setminus A \}.
\end{equation}
- Given a subset $A$ of $\mathbb{Z}^2$, its perimeter is $\text{Per}(A) := \sharp(\partial A)$
- A curve connecting $p$ and $q$ is a subset of $\mathcal{A}$ of the form \{ $(p_0, p_1), (p_1, p_2), \cdots, (p_{n-1}, p_n)$ \} with $p_0 = p$ and $p_n = q$. A loop or cycle is curve such that $p_n = p_0$. A graph is connected if any two points can be connected by a curve.
- Given a function $f : \mathbb{Z}^2 \to \mathbb{R}$ and $B \subset \mathbb{Z}^2$, its integral on $B$ is defined by
\begin{equation}
\int_B f := \sum_{p \in B} f(p).
\end{equation}
We denote also $f(B) = \int_B f$.
- Given a 1-form $\varphi$ and a curve $\gamma$, the integral of $\varphi$ on $\gamma$ is defined by
\begin{equation}
\int_{\gamma} \varphi := \sum_{a \in \gamma} \varphi(a)
\end{equation}
• Given two 1-forms \( \varphi \) and \( \phi \), their inner product is

\[
\langle \varphi, \phi \rangle := \frac{1}{2} \sum_{a \in A} \varphi(a)\phi(a)
\]

• Given a 1-form \( \varphi \) and a subset \( S \subset A \), the total variation of \( \varphi \) with respect to \( S \) is defined by

\[
[\varphi, S] := \frac{1}{2} \sum_{a \in S} |\varphi(a)|
\]

When \( S = A \), we simply write \([\varphi]\).

We have the following classical results.

**Lemma 5.** (Poincaré Lemma) Given a 1-form \( \varphi \), if one has \( \int_\gamma \varphi = 0 \) for any loop \( \gamma \), then there exists a function \( f \) satisfying

\[
\varphi = \nabla f
\]

**Proof.** One fixes some point \( p \in \mathbb{Z}^2 \) and for any \( q \in \mathbb{Z}^2 \) one defines \( f(q) := \int_{\mathcal{C}} \varphi \) where \( \mathcal{C} \) is any curve connecting \( p \) and \( q \). From the hypothesis, this definition is independent of the particular curve chosen, and it is easy to check that \( \varphi = \nabla f \). \( \square \)

**Lemma 6.** (Stokes’ formula) Let \( \varphi \) be a 1-form with compact support and \( f \) be a function with compact support. Then one has

\[
\langle \varphi, \nabla f \rangle = - \int_{\mathbb{Z}^2} f \text{div}(\varphi)
\]

**Proof.** We write \( \varphi \) as linear combination of elementary 1-forms

\[
\alpha_{(p,q)} := \delta_{\{(p,q)\}} - \delta_{\{(q,p)\}},
\]

and note that

\[
\langle \alpha_{(p,q)}, \nabla f \rangle = f(q) - f(p) = - \int_{\mathbb{Z}^2} f \text{div}(\alpha_{(p,q)}),
\]

since \( \text{div}(\alpha_{(p,q)}) = \delta_{\{p\}} - \delta_{\{q\}} \). \( \square \)

**Lemma 7.** (Coarea formula) Let \( f : \mathbb{Z}^2 \to \mathbb{R}_+ \) be a function with the compact support. Then one has

\[
[\nabla f] = \int_0^\infty \text{Per}(\{ f > t \}) dt
\]

**Proof.** We note that

\[
[\nabla f, \{(p,q),(q,p)\}] = |f(q) - f(p)|
\]

and

\[
\partial\{ f > t \} \cap \{(p,q),(q,p)\} = \begin{cases} (p,q) & \text{if } f(p) > t \text{ and } f(q) \leq t \\ (q,p) & \text{if } f(q) > t \text{ and } f(p) \leq t \\ \emptyset & \text{otherwise}, \end{cases}
\]

which implies that

\[
\sharp(\partial\{ f > t \} \cap \{(p,q),(q,p)\}) = \begin{cases} 1 & \text{if } f(p) > t \geq f(q) \text{ or } f(q) > t \geq f(p) \\ 0 & \text{otherwise} \end{cases}
\]
Therefore, we get
\[
\int_0^\infty \mathbb{E}(\partial \{ f > t \} \cap \{(p,q),(q,p)\}) dt = |f(q) - f(p)|.
\]
Summing with respect to all couples of edges \{(p,q),(q,p)\} proves the result.

We may now set up the duality argument. For any given 1-form \( \varphi \) we let
\[
\| \varphi \|_\infty = \sup_{(p,q) \in A} \varphi(p,q) = \sup \{ \langle \phi, \varphi \rangle \mid \phi \text{ is compactly supported}, \phi \leq 1 \},
\]
and define,
\[
\alpha := \min_{-\text{div}(\phi) = \mu_N} \max_{\| \phi \|_\infty \leq 1} \{ \langle \phi, \varphi \rangle \mid \phi \in C_0, \phi \leq 1 \},
\]
where \( C_0 \) is the set of compactly supported 1-forms.

**Lemma 8.** One has
\[
\alpha = \max_{\nabla f \in C_0, |\nabla f| \leq 1} \int_0^\infty \left( \int_{\{ f > t \}} \mu_N - \int_{\{ f < -t \}} \mu_N \right) dt.
\]

**Proof.** By convex duality, we obtain
\[
(42) \quad \alpha = \max_{\{ \phi \in C_0, |\phi| \leq 1 \}} \min_{-\text{div}(\phi) = \mu_N} \langle \phi, \varphi \rangle.
\]
Then given \( \phi \in C_0 \), we assume there exists a loop \( \gamma \) such that
\[
\int_\gamma \phi \neq 0.
\]
We may then define \( \varphi_t \) for any \( t \in \mathbb{R} \) by
\[
\varphi_t(a) := \begin{cases} t & \text{if } a \in \gamma \\ 0 & \text{otherwise} \end{cases}
\]
Since \( \gamma \) is a loop, \( \varphi_t \) has compact support and \( \text{div}(\varphi_t) = 0 \). Moreover, since \( \int_\gamma \phi \neq 0 \),
\[
\min_{t \in \mathbb{R}} \langle \phi, (\varphi + \varphi_t) \rangle = -\infty
\]
which implies
\[
\min_{-\text{div}(\phi) = \mu_N} \langle \phi, \varphi \rangle = -\infty.
\]
As a consequence, the maximum in \( (42) \) can be restricted to those \( \phi \)'s for which the integral on any loop is zero, i.e. to gradients, in view of Lemma 5. Therefore
\[
(43) \quad \alpha = \max_{\{ \nabla f \in C_0, |\nabla f| \leq 1 \}} \min_{-\text{div}(\phi) = \mu_N} \langle \nabla f, \varphi \rangle
\]
Now, from Lemma 6 we have
\[
\alpha = \max_{\{ \nabla f \in C_0, |\nabla f| \leq 1 \}} \min_{-\text{div}(\phi) = \mu_N} -\text{div}(\varphi) f = \max_{\{ \nabla f \in C_0, |\nabla f| \leq 1 \}} \int \mu_N f
\]
On the other hand, for any function \( f \) with compact support we have as a well known consequence of Fubini’s Theorem (see for instance [4], where this is named the bath-tub principle)
\[
\int \mu_N f = \int_0^\infty \left( \int_{\{ f > t \}} \mu_N \right) dt
\]
and
\[ \int_0^{+\infty} \mu_N f_+ = \int_0^{+\infty} \left( \int_{\{f < t\}} \mu_N \right) dt. \]
Together with \ref{43}, this proves the result. \hfill \Box

**Lemma 9.** Assuming Property I of Proposition \ref{0} there exists \( C > 0 \) such that for any integer \( N \) and any finite \( B \subset \mathbb{Z}^2 \), we have
\[ \mu_N(B) \leq 4CN \text{ Per}(B) \]

**Proof.** Let \( B_1, \ldots, B_k \) be the connected components of \( B \). Then we have disjoint unions \( B = \bigcup_{i=1}^k B_i \) and \( \partial B = \bigcup_{i=1}^k \partial B_i \). Set \( \tilde{B}_i := \bigcup_{p \in B_i} K^N_p \). We have \( \mu_N(B_i) = \sharp(\tilde{B}_i \cap \mathbb{A}) \), hence
\[ \mu_N(B_i) \leq C \text{ diam}(\tilde{B}_i) \]
Now assume \( \tilde{p} = (\tilde{p}_1, \tilde{p}_2) \) and \( \tilde{q} = (\tilde{q}_1, \tilde{q}_2) \) are in \( \tilde{B}_i \) and such that \( \text{diam}(\tilde{B}_i) = ||\tilde{p} - \tilde{q}|| \). Without loss generality, we may assume that \( ||\tilde{p} - \tilde{q}|| \leq 2(\tilde{p}_1 - \tilde{q}_1) \). There exists \( p = (p_1, p_2) \) and \( q = (q_1, q_2) \) in \( B_i \) such that \( \tilde{p} \in K^N_p \) and \( \tilde{q} \in K^N_q \). Moreover,
\[ \tilde{p}_1 - \tilde{q}_1 = N(p_1 - q_1) + (N-1) \leq N(p_1 - q_1) + 1. \]

On the other hand, from the connectedness of \( B_i \), for any integer \( x \in [p_1, q_1] \) we have \( B_i \cap \{x\} \times \mathbb{Z} \neq \emptyset \) hence writing \( m_x = \min\{y \mid (x, y) \in B_i\} \) and \( M_x = \max\{y \mid (x, y) \in B_i\} \), the two edges \( ((x, m_x), (x, m_x - 1)) \) and \( ((x, M_x), (x, M_x + 1)) \) belong to \( \partial B_i \). It follows that
\[ \text{Per}(B_i) = 2\partial B_i \geq 2(p_1 - q_1 + 1), \]
and then
\[ \mu_N(B_i) \leq CN \text{ Per}(B_i), \quad \mu_N(B) = \sum_i \mu_N(B_i) \leq CN \sum_i \text{ Per}(B_i) = CN \text{ Per}(B). \]

\hfill \Box

As a consequence, we obtain

**Corollary 3.** Assuming Property I of Proposition \ref{0} there exists \( C > 0 \) and for any integer \( N > 1 \) there exists a 1-form \( \varphi \) such that
\begin{equation}
- \text{div}(\varphi) = \mu_N
\end{equation}
and for every edge \( a \in \mathbb{A} \),
\begin{equation}
|\varphi(a)| \leq CN.
\end{equation}

**Proof.** It follows from Lemmas \ref{7} and \ref{9} that
\[ \int_0^{+\infty} \mu_N(\{f > t\}) \leq CN \int_0^{+\infty} \text{Per}(\{f > t\}) = CN[\nabla f_+] \]
and
\[ \int_0^{+\infty} \mu_N(\{f < -t\}) \leq CN \int_0^{+\infty} \text{Per}(\{f > t\}) = CN[\nabla f_-]. \]
This implies using Lemma \ref{8} that
\[ \alpha \leq CN \max_{\nabla f \in C_0, |\nabla f| \leq 1} |\nabla f| = CN. \]
Using the definition of \( \alpha \), there exists a 1-form \( \varphi \) with the desired properties (changing the constant to \( 2C \) for instance).

**Proof of Proposition 6.** We construct the bijective map \( \Phi : \Lambda \to \mathbb{Z}^2 \). This is done by specifying the for every \( p, q \in \mathbb{Z}^2 \) the number of points in \( \Lambda \cap K_p^N \) whose images by \( \Phi \) belong to \( \mathbb{Z}^2 \cap K_q^N \), as follows:

\[
 n_{p \to q} := \begin{cases} 
 \max(\varphi(p, q), 0) & \text{if } (p, q) \in \mathcal{A} \\
 \sharp(\Lambda \cap K_p^N) - \sum_{(p, q) \in \mathcal{A}} n_{p \to q} & \text{if } p = q \\
 0 & \text{otherwise},
\end{cases}
\]

where \( \varphi \) is a flow satisfying (44), (45).

Now, for the numbers \( n_{p \to q} \) to indeed correspond to a bijective map \( \Phi \) we need to check some of their properties.

**Property 1.** If \( N \) is chosen large enough, then for any \( p, q \in \mathbb{Z}^2 \), we have \( n_{p \to q} \geq 0 \). This is clear when \( p \neq q \). In the case \( p = q \), we note that there are exactly 4 edges coming out of \( p \). Thus, from (45) and the fact that \( \sharp(\Lambda \cap K_p^N) \geq N^2 -CN \) we find (with another constant \( C \) still independent of \( N \)).

\[
 n_{p \to p} \geq N^2 - CN.
\]

Thus we may indeed choose \( N \) large enough so that indeed \( n_{p \to q} \geq 0 \) for any \( p, q \in \mathbb{Z}^2 \).

**Property 2.** This one is clear from the definition of \( n_{p \to q} \): For any \( p \in \mathbb{Z}^2 \) we have

\[
 \sum_q n_{p \to q} = \sharp(\Lambda \cap K_p^N).
\]

**Property 3.** For any \( q \in \mathbb{Z}^2 \) we have

\[
 \sum_p n_{p \to q} = N^2.
\]

Indeed, fixing \( q \in \mathbb{Z}^2 \) and all the sums below being with respect to \( p \),

\[
 \sum_p n_{p \to q} = n_{q \to q} + \sum_{(p, q) \in \mathcal{A}} n_{p \to q}
 = \sharp(\Lambda \cap K_q^N) - \sum_{(q, p) \in \mathcal{A}} n_{q \to p} + \sum_{(p, q) \in \mathcal{A}} n_{p \to q}
 = \sharp(\Lambda \cap K_q^N) + \sum_{(p, q) \in \mathcal{A}, \varphi(p, q) \geq 0} \varphi(p, q) - \sum_{(q, p) \in \mathcal{A}, \varphi(q, p) \geq 0} \varphi(q, p).
\]

Now since \( \varphi(p, q) = -\varphi(q, p) \) we have

\[
 \sum_{(p, q) \in \mathcal{A}, \varphi(p, q) \geq 0} \varphi(p, q) = \sum_{(p, q) \in \mathcal{A}, \varphi(q, p) \geq 0} \varphi(q, p) = -\div \varphi(q).
\]

Using (44) this sum is equal to \( \mu_N(q) = N^2 - \sharp(\Lambda \cap K_q^N) \), hence \( \sum_p n_{p \to q} = N^2 \).
The three properties insure that there exists a bijection $\Phi : \Lambda \to \mathbb{Z}^2$ such that for any $p, q \in \mathbb{Z}^2$ we have

$$n_{p \to q} = \#\{x \in \Lambda \cap K^N_p | \Phi(x) \in \mathbb{Z}^2 \cap K^N_q\}.$$ 

Since $n_{p \to q} \neq 0$ implies $\|p - q\| \leq 1$, we find that $\|\Phi(x) - x\| \leq 2 \text{diam}(K^N)$, for any $x \in \Lambda$. \qed

**Remark 4.** The conclusion of Theorem 3 holds under the following, less restrictive assumption on $\Lambda$, which is assumed to be uniform, but not necessarily a subset of $\mathbb{Z}^2$:

i) There exists some positive constant $C > 0$ such that for any $x \in \mathbb{R}^2$ and any $R > 1$, one has $|\sharp(\Lambda \cap B(x, R)) - \pi R^2| \leq CR$.

ii) There exists some positive integer $N_0 \in \mathbb{N}$ such that for any $p \in \mathbb{Z}^2$, one has $\sharp(K^{N_0}_p \cap \Lambda) \leq N_0^2$.

Indeed, the second assumption, implies that there exists an injective map

$$\Phi_p : K^{N_0}_p \cap \Lambda \to K^{N_0}_p \cap \mathbb{Z}^2.$$ 

We define $\Phi : \Lambda \to \mathbb{Z}^2$ to be the injective map whose restriction to $K^{N_0}_p$ is $\Phi_p$ for any $p \in \mathbb{Z}^2$ and let $\Lambda_1 = \Phi(\Lambda)$. Then $\Lambda_1$ is of the form $\mathbb{Z}^2 \setminus A$, with $A$ satisfying (40). Theorem 3 implies that $\bar{W}(\Lambda_1) < +\infty$ and then from (2) we deduce that $\bar{W}(\Lambda) < +\infty$.

We conclude this section with

**Theorem 3'.** Let $\Lambda \subset \mathbb{R}^2$ be discrete and uniform, and of the form $\Lambda = \Lambda_1 \times \mathbb{Z}$, where $\Lambda_1 \subset \mathbb{R}$.

If there exists $C > 0$ such that for any $x \in \mathbb{R}^2$ and $R > 1$ we have $|\sharp(\Lambda \cap K(x, R)) - \pi R^2| \leq CR$ — where $K(x, R)$ is the square with sidelength $R$ and center $x$ — then $\bar{W}(\Lambda) < +\infty$.

**Proof.** The proof of the theorem will follow the same strategy as for Theorem 3 except that we work now in one dimension. For any integer $N > 0$ and $p \in \mathbb{Z}$ we let $I^N_p = [pN, (p+1)N)$ and $\mu^N(p) = N - \sharp(\Lambda_1 \cap I^N_p)$. We consider the graph with $\mathbb{Z}$ as the set of vertices and the set of edges

$$A = \{(p, q) \mid p, q \in \mathbb{Z}, |p - q| = 1\}.$$ 

We claim that there exists $C > 0$, and for any integer $N > 0$ a 1-form $\varphi : A \to \mathbb{R}$ such that

$$-\text{div}(\varphi) = \mu_N, \quad \|\varphi\|_{\infty} \leq C.$$  

Indeed we define $\varphi$ as follows:

$$\varphi((k, k+1)) = \begin{cases} 0 & \text{if } k = 0 \\ -\sum_{i=0}^{k} \mu_N(i) & \text{if } k \geq 1 \\ \sum_{i=k+1}^0 \mu_N(i) & \text{if } k < 0. \end{cases}$$

It is clear that $-\text{div}(\varphi) = \mu_N$. Moreover, for instance if $k \geq 1$, then

$$\varphi((k, k+1)) = -\sum_{i=1}^{k} (N - \sharp(\Lambda_1 \cap I^N_p)) = \sharp(\Lambda_1 \cap [N, (k+1)N)) - kN.$$
But considering the square $K = [N, (k + 1)N] \times [N, (k + 1)N]$, we have

$$kN - \sharp (\Lambda_1 \cap [N, (k + 1)N]) = \frac{1}{kN} \left( (kN)^2 - \sharp (\Lambda \cap K) \right),$$

and thus using the hypothesis of the theorem we deduce that $|\varphi((k, k + 1))| \leq C$ as claimed.

Now we choose $N \geq 2C + 1$ and following the proof of Proposition 6 we can construct a bijective map $\Phi : \Lambda_1 \to \mathbb{Z}_2$ such that $|\varphi(\Phi(p) - p)|$ is bounded independently of $p$. This induces a bijection with the same property from $\Lambda$ to $\mathbb{Z}_2$, which proves Theorem 5, using Proposition 2.

6. A Penrose lattice

We now describe the construction of a Penrose-type lattice $\Lambda$ such that $\tilde{W}(\Lambda) < +\infty$. Of course it would be better to show that $\Lambda$ satisfies the hypothesis of Theorem 2, but this is an open problem.

For the simplicity, we consider the Robinson triangle decompositions in the Penrose’s second tiling (P2)–kite and dart tiling, or in the Penrose’s third tiling (P3)–rhombus tiling, (for the reference see [8]). The construction is as follows: $\Omega_1$ and $\Omega_2$ are two Robinson triangles, namely, $\Omega_1$ is an acute Robinson triangle having side lengths $(1, 1, \varphi)$, while $\Omega_2$ is obtuse one with sidelengths $(\varphi, \varphi, 1)$, where $\varphi = (1 + \sqrt{5})/2$; the scaled-up domain $\varphi \Omega_1$ decomposes as the union of a copy of $\Omega_1$ and a copy of $\Omega_2$, where the interiors are disjoint — and such that $\varphi \Omega_2$ decomposes as the union of one copy of $\Omega_1$ and two copies of $\Omega_2$ with disjoint interiors (see figure).

For $i = 1, 2$ we choose a point $p_i$ in the interior of $\Omega_i$.

Then we proceed by induction, starting with $\Omega_1$ choosing $p_1$ as the origin, then scaling up by $\varphi$, then decomposing, then scaling up again, then decomposing each piece, etc... After $n$ steps we have a (large domain) $\varphi^n \Omega_1$ decomposed a number of copies of either $\Omega_1$ or $\Omega_2$. In each copy we have a distinguished point, the union of which is denoted $\Lambda_n$. As $n \to +\infty$ and modulo a subsequence, $\Lambda_n$ converges to a discrete set $\Lambda$, which is uniform since the distance between two point is no less than $\min (d(p_1, \partial \Omega_1), d(p_2, \partial \Omega_2))$.

**Theorem 4.** We have $\tilde{W}(\Lambda) < +\infty$.

**Proof.** For each $n$ we define a current $j_n$ as follows. On each copy of $\Omega_i$ we let $j_n$ be equal to (a copy of) $\nabla U_i$, where

$$\begin{align*}
-\Delta U_i &= \delta_{p_i} - \frac{1}{|\Omega_i|} \quad \text{in } \Omega_i \\
\frac{\partial U_i}{\partial \nu} &= 0 \quad \text{on } \partial \Omega_i.
\end{align*}$$

Then $j_n$ converges as $n \to +\infty$ to a current $j$ such that the following holds in $\mathbb{R}^2$

$$-\text{div}(j) = \sum_{p \in \Lambda} \delta_p - \alpha,$$

where $\alpha = 1/|\Omega_i|$ on each copy of $\Omega_i$. It is not difficult to check that $W(j) < +\infty$, but the background density $\alpha$ is not constant. We need to add a correction to $j$, which is the object of the following

**Lemma 10.** There exist $m \in \mathbb{R}$ and a solution of the following equation in $\mathbb{R}^2$

$$-\text{div}(j') = \alpha - m \quad (47)$$
such that \( \|j'\|_\infty < +\infty \),

Assuming the lemma is true we let \( \tilde{j} = j + j' \). Then \( -\text{div}(\tilde{j}) = \sum_{p \in \Lambda} \delta_p - m \) thus \( \tilde{j} \in \mathcal{G}_\Lambda \) for the background \( m \), and the fact that \( W(j) < +\infty \) and \( j' \in L^\infty \) implies that \( W(\tilde{j}) < +\infty \) and the Theorem.

**Proof of Lemma 10.** The current \( j' \) is obtained as the limit of \( j_n \), where \( j_n \) solves

\[
\begin{cases}
-\text{div}(j_n) &= \alpha_n - m_n \quad \text{in } \varphi^n\Omega_1 \\
 j_n \cdot \nu &= 0 \quad \text{on } \partial(\varphi^n\Omega_1),
\end{cases}
\]

where \( \alpha_n : \varphi^n\Omega_1 \to \mathbb{R} \) is the function equal to \( 1/|\Omega_i| \) on each of the copies of \( \Omega_i, i = 1, 2 \) which tile \( \varphi^n\Omega_1 \), and where \( m_n \) is equal to the average of \( \alpha_n \) on \( \varphi^n\Omega_1 \).

The current \( j_n \) is defined recursively. First we define the equivalent of \( \alpha_n \) for \( \Omega_2 \)-type domains: For any integer \( n \) we tile \( \varphi^n\Omega_2 \) by one copy of \( \varphi^{n-1}\Omega_1 \) and two copies of \( \varphi^{n-1}\Omega_2 \), then we tile each of the three pieces, etc... until we have tiled \( \varphi^n\Omega_2 \) by copies of either \( \Omega_1 \) or \( \Omega_2 \). then we let \( \beta_n : \varphi^n\Omega_2 \to \mathbb{R} \) be the function equal to \( 1/|\Omega_i| \) on each of the copies of \( \Omega_i, i = 1, 2 \). We also define \( q_n \) to be the equivalent of \( m_n \), i.e. the average of \( \beta_n \) on \( \varphi^n\Omega_2 \).
Finally we define \( \tilde{j}_n \) to be the equivalent of \( j_n \) for type 2 domains, i.e. the solution of \([48]\) with \( \alpha_0 \) replaced by \( \beta_0 \), \( m_n \) replaced by \( q_n \) and \( \Omega_1 \) replaced by \( \Omega_2 \).

Below it will be convenient to abuse notation by writing \( \varphi^n \Omega_i \) for a copy of \( \varphi^n \Omega_i \). Then we have \( \varphi^n \Omega_1 = \varphi^{n-1} \Omega_1 \cup \varphi^{n-1} \Omega_2 \). We let
\[
(49) \quad \tilde{j}_n = j_{n-1} \mathbf{1}_{\varphi^{n-1} \Omega_1} + j_{n-1} \mathbf{1}_{\varphi^{n-1} \Omega_2} + \nabla U_n \mathbf{1}_{\varphi^n \Omega_1},
\]
where
\[
(50) \quad \begin{cases}
- \triangle U_n & = (m_n - m_{n-1}) \mathbf{1}_{\varphi^{n-1} \Omega_1} + (m_n - q_{n-1}) \mathbf{1}_{\varphi^{n-1} \Omega_2} & \text{ in } \varphi^n \Omega_1 \\
\frac{\partial U_n}{\partial \nu} & = 0 & \text{ on } \partial(\varphi^n \Omega_1).
\end{cases}
\]

It is straightforward to check that \( \tilde{j}_n \) satisfies \([48]\) assuming \( \tilde{j}_{n-1} \) and \( \tilde{j}_{n-1} \) do.

The relation \([49]\) is the recursion relation which repeated \( n \) times allows to write \( j_n \) as equal to a sum of on the one hand error terms \( \nabla U_k \) (or their type 2 equivalent that we denote \( V_k \)), for \( k \) between 1 and \( n \), and on the other hand of a vector field which on each elementary tile of type \( \Omega_1 \) of \( \varphi^n \Omega_1 \) is equal to \( j_0 \) and on a tile of type \( \Omega_2 \) is equal to \( \tilde{j}_0 \). However from \([48]\) we may take \( j_0 = 0 \) and \( \tilde{j}_0 = 0 \), thus we are left with evaluating the error terms.

**Claim:** There exists \( C > 0 \) such that for any integer \( k > 0 \) we have
\[
\| \nabla U_k \|_{\infty}, \| \nabla V_k \|_{\infty} \leq C \varphi^{-3k}.
\]

This clearly proves that the sum of errors for \( k = 1 \ldots n \) is bounded in \( L^{\infty} \) independently of \( n \) and therefore that \( \{j_n\} \) is bounded in \( L^{\infty} \). Then the limit \( j' \) is in \( L^{\infty} \).

To prove the lemma, it remains to prove the claim, and to show that \( j' \) satisfies \([47]\) for some \( m \in \mathbb{R} \), which in view of \([48]\) amounts to showing that \( \{m_n\} \) converges. For this we define \( u_{2n} \) (resp. \( u_{2n+1} \)) be the number of elementary tiles of type \( \Omega_1 \) (resp. \( \Omega_2 \)) in \( \varphi^n \Omega_1 \). We define similarly \( v_{2n} \) and \( v_{2n+1} \) by replacing \( \Omega_1 \) by \( \Omega_2 \). Therefore \( u_0 = 1, v_0 = 0, v_1 = 1 \). We have the following recurrence relations
\[
u_{2n+2} = u_{2n} + u_{2n+1}, \quad u_{2n+3} = u_{2n} + 2u_{2n+1},
\]
which we can summarize as the single relation \( u_{n+2} = u_{n+1} + u_n \). Similarly \( v_{n+2} = v_{n+1} + v_n \). It follows that
\[
u_n = \varphi^n \frac{1}{\varphi + 2} + (-\varphi)^{-n} \frac{\varphi + 1}{\varphi + 2}, \quad v_n = \varphi^n \frac{\varphi}{\varphi + 2} + (-\varphi)^{-n} \frac{-\varphi}{\varphi + 2}.
\]
We have \( u_n = a \varphi^n + O(\varphi^{-n}) \) and \( v_n = b \varphi^n + O(\varphi^{-n}) \) with \( a = \frac{1}{\varphi + 2} \) and \( b = \frac{\varphi}{\varphi + 2} \) strictly positive. Then we easily deduce that
\[
m_n = \frac{u_{2n} + u_{2n+1}}{u_{2n} |\Omega_1| + u_{2n+1} |\Omega_2|} = m + O(\varphi^{-4n}),
\]
where
\[
m = \frac{1 + \varphi}{|\Omega_1| + \varphi |\Omega_2|},
\]
and similarly that \( q_n = m + O(\varphi^{-4n}) \). This proves in particular the convergence of \( \{m_n\} \). Moreover it shows that the right-hand side of \([50]\) is bounded by \( C \varphi^{-4n} \). By elliptic regularity (lemma 3 and lemma 4) we deduce that
\[
\| \nabla U_n \|_{\infty} \leq C |\varphi^n \Omega_1|^\frac{1}{4} \varphi^{-4n} = C |\Omega_1|^\frac{1}{4} \varphi^{-3n},
\]
and a similar bound for \( V_n \). This proves the claim, and the lemma \( \square \).
Remark 5. The above construction could easily be generalized to similar recursive constructions.

Acknowledgments. The authors wish to thank Y.Meyer for helpful discussions.
