Backflow Transformations via Neural Networks for Quantum Many-Body Wave-Functions

Di Luo\(^1\) and Bryan K. Clark\(^1\)

\(^1\)Institute for Condensed Matter Theory and Department of Physics, University of Illinois at Urbana-Champaign, IL 61801, USA

Obtaining an accurate ground state wave function is one of the great challenges in the quantum many-body problem. In this paper, we propose a new class of wave functions, neural network backflow (NNB). The backflow approach, pioneered originally by Feynman\([1]\), adds correlation to a mean-field ground state by transforming the single-particle orbitals in a configuration-dependent way. NNB uses a feed-forward neural network to find the optimal transformation. NNB directly dresses a mean-field state, can be systematically improved and directly alters the sign structure of the wave-function. It generalizes the standard backflow\([2]\) which we show how to explicitly represent as a NNB. We benchmark the NNB on a Hubbard model at intermediate doping finding that it significantly decreases the relative error, restores the symmetry of both observables and single-particle orbitals, and decreases the double-occupancy density. Finally, we illustrate interesting patterns in the weights and bias of the optimized neural network.

Introduction—A key question in strongly correlated quantum systems is to obtain an approximation for the ground state wave function. This is especially important for Fermion systems in two or more dimensions where only approximate or exponentially costly methods for evaluating observables of quantum systems exist. Early attempts for writing down variational Fermion wave-functions, such as Slater determinants [3] and BCS wave-functions[4], focused on finding the ground state of a mean field Hamiltonian which best matched the interacting ground state. Since these early attempts more sophisticated wave-functions have been developed which dress these mean-field starting points including Slater-Jastrow \([5, 6]\), Slater-Jastrow-Backflow \([1, 7]\) and iterative backflow \([8]\) which has recently been described as a non-linear network \([9]\). These wave-functions have the advantage that the mean-field starting point can directly incorporate the basic physics of the problem.

Instead of starting from a dressed mean-field, many other classes of wave-functions are parameterized by a tuning parameter \(D\) which interpolates from a trivial state at small \(D\) to a universal wave-function spanning the entire Hilbert space at exponential \(D\). Examples of such wave-functions include matrix-product states\([10, 11]\), other forms of tensor networks\([11–13]\), Huse-Elser states\([14–16]\), and string-bond states \([17]\). Recently, wave-functions based on neural network primitives, such as restricted Boltzmann machines (RBM) and feed forward neural network (FNN), have been introduced with similar universal properties\([18–38]\); as the number of hidden neurons increases, the neural network state can represent all probability distributions. Unfortunately, RBM with real weights and bias\(^1\) can not represent the sign structure of Fermion wave-functions; a recent attempt to incorporate RBM into Fermion states by using the RBM as a more general Jastrow \([23]\) shows promise but is still restricted to the sign-structure of the underlying mean-field ansatz. Even neural networks beyond RBM\([26, 28, 38]\) which alter the sign-structure may struggle with capturing the underlying mean-field physics both in terms of the number of neurons required as well as optimization.

In this work, we propose a new class of wave-functions, the Neural Network Backflow (NNB), which dresses a mean-field wave-function, can make changes to the sign structure directly, and can be systematically improved. To accomplish this we use a feed-forward neural network (FNN), not in the standard approach of returning a wave-function amplitude, but instead to transform the single particle orbitals in a configuration dependent way; these orbitals are then used in the mean-field wave-function. Wave-functions with configuration-dependent orbitals are known as a backflow wave-function\([1, 2, 7–9, 39–51]\).

Background.—Mean field theory - approximating the ground state of a quartic Hamiltonian by the ground state, \(\psi_{MF}\), of a quadratic Hamiltonian - is a powerful

---

\(^1\)Initially, RBM with real weights and bias was not capable of representing the sign structure of Fermion wave-functions. However, recent advancements have allowed for this restriction to be lifted, allowing for more general applications in quantum many-body problems.

---

Figure 1. Cartoon of (spin-up) neural network being used in this work for a NN (other transformations are similar) with input shown for the configuration displayed of 4 electrons on 3 sites. Every layer is fully connected with arrows but only a fraction of them are shown for image clarity. The input layer is set by the configuration. The output layer is a \(n_{\text{up-electrons}} \times n_{\text{down-electrons}}\) (i.e. \(2 \times 3\)) matrix which will be the backflow transformation added to the single particle orbitals.
wave function ansatz

\[ \psi_{SD}(r) = \det[M_{SD}^{\uparrow}] \det[M_{SD}^{\downarrow}] \]  
\[ M_{ik}^{SD,\sigma} = \phi_{k\sigma}(r_{i\sigma}) \]  

and Bogoliubov de Gennes wave-functions,

\[ \psi_{BDG}(r) = \det[\Phi] \]  
\[ \Phi_{ij} = \sum_{k,l} \phi_{k\uparrow}(r_{i\uparrow}) S_{kl} \phi_{l\downarrow}(r_{j\downarrow}) \]

where \( \phi_{k\sigma} \) is the \( k \)'th single particle orbital and \( r_{i\sigma} \) is the position of the \( i \)'th particle of spin \( \sigma \). Eq. (1) only takes the occupied orbitals while Eq. (3) is summed over both occupied and unoccupied orbitals.

Mean field states are uncorrelated by construction. The simplest way to capture correlation physics is through the introduction of a Jastrow giving \( \psi_{Jastrow}(r) = \exp[-U(r)]\psi_{MF}(r) \), where \( U(r) \) is an arbitrary function. In this work, we always use a charge Jastrow \( U(r) = \frac{1}{2} \sum_{i,j} v_{ij} n_{i} n_{j} \), where \( n_{i} \) is the charge density, \( v_{ij} \) are variational parameters. While Jastrow factors can introduce many-body correlations, they can’t modify the mean-field’s sign structure. One approach to add additional sign-structure modifying correlation is to add additional sign-structure modifying correlation is to add a backflow correction [2, 7–9, 39–51] which introduces correlations by having the single-particle orbitals act on a configuration-dependent quasi-particle position. On lattice models, this is equivalent to a configuration-dependent mean-field - i.e. the quadratic Hamiltonian or density, \( v \), neuron of the FNN. We use one neural net for each of the \( 2N \) orbitals where each value of \( a_{ij}^{N\downarrow} \) is represented by an output neuron of the FNN. Statistical error bars are shown but smaller than the marker size.

Neural Network Backflow - The NNB uses a FNN to modify the single particle orbitals for a spin \( \sigma \),

\[ \phi^{b}_{k\sigma}(r_{i\sigma}; r) = \phi_{k\sigma}(r_{i\sigma}) + a^{NN}_{kij\sigma}(r) \]  

where each value of \( a^{NN}_{ij\sigma} \) is represented by an output neuron of the FNN. We use one neural net for each of \( \sigma \in \{\uparrow, \downarrow\} \). This is to be contrasted with the standard backflow parameterization,

\[ \phi^{b}_{k\sigma}(r_{i\sigma}; r) = \phi_{k\sigma} + \sum_{j} \eta_{ij\sigma} \phi_{k\sigma}(r_{j\sigma}) \]  

with \( D_{i} = n_{i\uparrow} n_{i\downarrow} \), \( H_{i} = (1 - n_{i\uparrow})(1 - n_{i\downarrow}) \). \( \eta_{i\sigma} \) and \( \theta_{i\sigma} \) are the only non-zero variational parameters.

Interestingly, the backflow transformation of Eq. (6), can be represented as a neural network for \( a^{NN}_{ij\sigma}(r) \) with three hidden layers and a linear number of neurons; an explicit construction will be given in the next section. This ensures that there exists a three layer neural network which is at least as good as the standard backflow transformation.

We consider two NNB wave-functions, \( \Psi_{SN} \) and \( \Psi_{PN} \), implemented on top of a Slater Determinant and BCS pairing wave-functions respectively. The neural nets used in these wave-functions are similar although \( \Psi_{SN} \) has outputs which only correspond to the occupied orbitals, while the outputs of \( \Psi_{PN} \) correspond to all the orbitals. In addition, for \( \Psi_{SN} \) there are only two neural nets (one for each of the spin-up and spin-down orbitals) while for \( \Psi_{PN} \) there is an additional neural net used to generate a system dependent \( S_{kl}(r) \). This is implemented by letting \( S_{kl}(r) = S_{kl} + d^{NN}_{kl}(r) \), where \( d^{NN}_{kl}(r) \) is represented by an FNN (in this work always fixed to 16 hidden neurons) that inputs the system configuration \( r \) and outputs the symmetric matrix correction \( d^{NN}_{kl} \). Notice that \( \Psi_{PN} \) is trivially a superset of \( \Psi_{SN} \).

Figure 2. Left: Relative error from the exact ground-state energy of Eq. 7 \( E = -11.868[52] \), for various classes of wave-functions. The star is the variance extrapolation result of \( \Psi_{PN} \) (see Fig. 7). Right: Relative energy error as a function of \( 1/m \) for NNB. Statistical error bars are shown but smaller than the marker size.

Although various architectures can be used, we adopt a three-layer fully-connected FNN for each of the functions \( a^{NN}_{ki\sigma} \) and \( d^{NN}_{kl} \) (see Fig. 1). The input layer has \( 2N \) neurons with neuron \( i \) (neuron \( i + N \) outputting 1 if there is spin up (spin down) on site \( i \) and -1 otherwise, where \( N \) is the total system size. The hidden layer contains \( mN \) hidden neurons for constant \( m \) with Rectifier Linear Units (ReLU) [53] activation functions. The output layer then contains \( O(N^2) \) neurons specifying the values of the respective functions. Gradients are computed in the standard way using variational Monte Carlo (see Appendix. B) which requires evaluating the derivative of the wave-function with respect to the weights and bias in the neural network. Derivatives for FNN are typically taken using back-propagation. Because the wave-function is a determinant of a matrix generated by the neural-network output, we evaluate this full derivative by envisioning this determinant as an additional final layer of the neural network and then performing back-propagation including this layer. This ensures the cost
of computing all the derivatives is of the same order as
the evaluation of the wave-function (see Appendix. C for
details concerning these gradients). Optimization is per-
formed by stepping each parameter in the direction of the
gradient with a random magnitude; this helps us avoid
shallow local minima [54].

The computational complexity of the NNB imple-
mented with a single layer of $O(mN)$ hidden neurons
scales as $O(mN^3)$ per sweep (i.e. after $N$ electrons move)
for forward and backward propagation and $O(N^3)$ per
sweep for the evaluation of the mean-field determinant.
This is similar to the scaling of standard backflow.

\begin{table}
\centering
\begin{tabular}{|l|l|l|l|}
\hline
method & backflow transformation & mean field & variational functions \\
\hline
$\psi_0$ & $\phi^\alpha_{\sigma}(r_{i\sigma};r) = \phi_{\sigma}(r_{i\sigma}) + a^{\sigma N}_{i\sigma}(r)$ & Eq. (1) & $\phi_{\sigma}(r_{i\sigma}),\phi_{\sigma}(r_{i\sigma}),v_{ij}$ \\
$\Psi_{SN}$ & $\phi^\alpha_{\sigma}(r_{i\sigma};r) = \phi_{\sigma}(r_{i\sigma}) + \theta_{\sigma} \sum_j tD_j H_j \phi_{\sigma}(r_{j\sigma}) + \theta_{\sigma} \sum_j tD_j H_j \phi_{\sigma}(r_{j\sigma})$ & Eq. (1) & $a^{\sigma N}_{i\sigma}(r),v_{ij}$ \\
$\Psi_{PB}$ & $\phi^\alpha_{\sigma}(r_{i\sigma};r) = \phi_{\sigma}(r_{i\sigma}) + a^{\sigma N}_{i\sigma}(r)$ & Eq. (3) & $\theta_{\sigma} \theta_{\sigma},v_{ij}$ \\
$\Psi_{PN}$ & $\phi^\alpha_{\sigma}(r_{i\sigma};r) = \phi_{\sigma}(r_{i\sigma}) + a^{\sigma N}_{i\sigma}(r); S_{b\sigma}(r) = S_{b\sigma} + d^{\sigma N}_{b\sigma}(r)$ & Eq. (3) & $a^{\sigma N}_{i\sigma}(r),d^{\sigma N}_{b\sigma}(r),v_{ij}$ \\

from $\Psi_{PN}$ with 8 hidden neurons (left) and 128 hidden
neurons (right).

\textit{Explicit construction of standard backflow}.—In this
section, we provide an explicit construction which re-
sents the standard backflow transformation in the form
of Eq. (6) written as a NNB.

In Eq. (6), $\eta_{ij,\sigma} = tD_i H_j \theta_{|i-j|,\sigma} =
\sum_{i,j}^\sigma n_i^\uparrow n_j^\uparrow h_{ij}^\uparrow \theta_{|i-j|,\sigma}$, where $h_{ij} = 1 - n_{ij}$, $\theta_{1,\sigma}$
and $\theta_{2,\sigma}$ are the only non-zero variational param-
ters. We first demonstrate that $\eta_{ij,\sigma}$ can be presented
by a two layer neural network with input layer as
$(\sigma_1, ..., \sigma_N, \sigma_{N+1}, ..., \sigma_{2N})$ where $\sigma_i = 2n_i^\uparrow - 1$ and
$\sigma_{i+N} = 2n_i - 1$. By construction, $n_i$ and $h_{ij}$
take value of 0 or 1 so that $n_i^\uparrow n_j^\uparrow h_{ij}^\uparrow$ is 1 if and
only if $n_i^\uparrow = n_j^\uparrow = h_{ij}^\uparrow = h_{ij} = 1$. Therefore,
$t\theta_{|i-j|,\sigma} D_i H_j \theta_{|i-j|,\sigma}$ is equivalent to
ReLU[$\theta_{|i-j|,\sigma}(n_i^\uparrow + n_j^\uparrow) + h_{ij}^\uparrow + h_{ij} - 3)$],
which is the same as ReLU[$\theta_{|i-j|,\sigma}(\sigma_i^2 + \sigma_{i+N}^2 -
\sigma_j^2/2 - \sigma_{j+N}^2/2 - 1)$]. As a result, for each $\eta_{ij,\sigma}$,
we associate it with a hidden neuron, such that
the weights connecting it to $\sigma_i, \sigma_{i+N}, \sigma_j, \sigma_{j+N}$ are
$t\theta_{|i-j|,\sigma}/2, \theta_{|i-j|,\sigma}/2, -t\theta_{|i-j|,\sigma}/2, -t\theta_{|i-j|,\sigma}/2$
respectively, the bias is $-t\theta_{|i-j|,\sigma}$ and the activation function is
ReLU. In general, for more complicated backflow [42, 43]
with terms $n_i h_{i-\sigma} n_j h_{j-\sigma}$, $n_i n_j h_{i-\sigma} h_{j-\sigma}$ and
$n_i h_{i-\sigma} h_{j-\sigma} h_{j-\sigma}$, where $\sigma$ is the spin index, we can use
more hidden neurons and represent it in the same way.

After we have the neural network construction for
the standard $\eta_{ij,\sigma}$, the term $a^{\sigma N}_{i\sigma} = \sum_j \eta_{ij,\sigma} \phi_{\sigma}(r_{ij})$
in Eq. (5) can be realized through an extra layer tak-
ing the outputs $\eta_{ij,\sigma}$ to a neuron representing $a_{ki}$
where the weight is given by the single particle orbital values
$\phi_{\sigma}(r_{ij})$, there is no bias and the activation function is
the identity. This construction shows that the stan-
ard backflow parameterization is thus a superset of our
three-layer NNB.

\textbf{Results}.—We have benchmarked the quality of our
NNB on a $4 \times 4$ square Hubbard model

$$H = -t \sum_{i\sigma} (c_{i+1\sigma}^\dagger + h.c.) + \sum_i U n_{i\uparrow} n_{i\downarrow}$$

(7)

where $U/t = 8$ and filling $n = 0.875$. We compare the
results to an optimized unrestricted (i.e. different single
particle-orbitals for spin-up and spin-down) Slater Deter-
minant ($\psi_0$) as well as a backflow BDG wave function
($\Psi_{PB}$) which transforms single particle orbitals of each
spin by Eq. (6). The formulation and the variational pa-
rameters of each wave function ansatz are summarized in Table I. The parameters which aren’t optimized, such as
the initial set of orbitals $\{\phi_{\sigma}(r_{ij})\}$ are obtained for
$\Psi_{PB}$ and $\Psi_{SN}$ by optimizing a restricted Slater-Jastrow
wave-function while $\Psi_{PN}$ uses orbitals taken from the
free hopping Hamiltonian (in practice the nature of the
neural net allows for a direct change to the orbitals by
altering the bias’ on the final layer).

The relative error of the energy of NNB is 1.4% (and
0.66% after variance extrapolation (see Fig. 7)) which is
significantly better then the standard wave-functions
(see Fig. 2(left)). We examine the effect of the number of
hidden neurons $mN$ (see Fig. 2(right)). We find that at
small hidden neuron number, $\Psi_{PN}$ is much better than
$\Psi_{SN}$ but this advantage eventually largely disappears at
large neuron number suggesting that a backflow parameter-
ized with a small neural networks can compensate for
the missing pairing in a Slater-determinant. Surprisingly
in the regime we’ve probed both NNB have energies lin-
ear with respect to $1/m$ in spite of the fact that in the
$m \to \infty$ limit, they both must become exact[55].
Another observation is that more neurons tend to take the relation between spin-up and spin-down configurations. These weights for both the spin-up and spin-down neural networks are performed by two different neural networks, they produce similar backflow transformed orbitals and roughly preserves the symmetry of spin up and spin down for a given configuration. This is different from the optimized unrestricted Slater Determinant $\Psi_{SO}$, which breaks the spin up and spin down symmetry significantly (see Fig. 4 (Left)).

One feature of using a NNB is the ability to alter the sign-structure of the wave-function. Here we consider the amount the sign changes between $\Psi_{SN}$ with 16 hidden neurons and $\Psi_{SO}$ by evaluating the integral

$$\frac{\int |\Psi_{SO}(x)|^2 \text{sgn}(\Psi_{SN}(x)) \text{sgn}(\Psi_{SO}(x)) dx}{\int |\Psi_{SO}(x)|^2 dx}$$

which is approximately 0.815 giving a 9% difference between the signs.

Furthermore, we open up the $\Psi_{SN}$ neural network for $m = 8$ and analyze the weight between the input layer and the hidden layer, which represents the features that the neural network learns from input. In Fig. 5, we plot these weights for both the spin-up and spin-down neural networks. Interestingly the spin-up neural network primarily has large weights connected to the spin-down configurations while the spin-down neural network primarily has large weights connected to the spin-up configurations. This allows the neural network to introduce correlation between spin-up and spin-down configurations. Another observation is that more neurons tend to take large weight in negative bias, and small weight in positive bias.

Conclusion.—In this paper, we utilize the generality of artificial neural networks and the physical insight from backflow to develop a new class of wave function ansatz, the neural network backflow wave function, for strongly correlated Fermion systems on lattice. It achieves good performance for Hubbard model at nontrivial filling. While this work has focused on Fermion system on the lattice, the NNB is straightforward to generalize to frustrated spin systems as well as the continuum. In the latter case, the input could be represented as a lexicographically ordered set of particle locations. Our work provides a new approach toward combining machine learning methodology with dressed mean-field variational wavefunctions which allows us to take simultaneous advantage of their respective strengths.

Appendix A: Numerical Results on neural network backflow of standard form

We have shown that the standard backflow can be represented by a three layer neural network. In practice, we have also investigated the neural network in the following form.

\[ \phi_{k\sigma}^{b}(r_{i,\sigma}; r) = \phi_{k\sigma} + \sum_{j} \eta_{ij,\sigma}^{NN} \phi_{k\sigma}(r_{j,\sigma}) \]  

(A1)

where \( \eta_{ij,\sigma}^{NN} \) is represented by a three layer neural network as the one used for \( a_{ij,\sigma}^{NN} \).

Figure 6. Relative energy error as a function of \( 1/m \) for \( \Psi_{SN}, \Psi_{SN-b} \) and \( \Psi_{PN} \). Statistical error bars for energy are shown.

We implement this backflow transformation in the Slater Determinant mean field, which is named as \( \Psi_{SN-b} \). Notice that \( \Psi_{SN-b} \) can also be represented by \( \Psi_{SN} \) since we can define \( a_{ij,\sigma}^{NN} = \sum_{j} \eta_{ij,\sigma}^{NN} \phi_{k\sigma}(r_{j,\sigma}) \). In practice, \( \Psi_{SN} \) and \( \Psi_{SN-b} \) have similar performance in computing energy and doublon density (see Fig. 6, Fig. 7 and Fig. 8).

Figure 7. Extrapolation of relative energy error vs. variance of \( \Psi_{SN}, \Psi_{SN-b} \) and \( \Psi_{PN} \). Statistical error bars for energy and variance are shown.

Appendix B: Optimization Scheme

Given a wave function \( \psi \) and Hamiltonian \( H \), the energy \( E = \langle \psi | H | \psi \rangle \). For any variational parameter \( t \), to compute the derivative \( \frac{dE}{dt} \) in quantum Monte Carlo, we define the local energy \( E_{L} = \langle r | H | r \rangle \), where \( r \) is a system configuration. Then the derivative can be computed through Monte Carlo sampling.

\[ \frac{\partial E}{\partial t} = 2 \left( \langle E_{L}(1 \frac{\partial \psi}{\partial t}) \rangle - \langle \frac{1}{\psi} \frac{\partial \psi}{\partial t} \rangle \right) \]  

(B1)

where \( \langle \ldots \rangle \) is averaged over the Monte Carlo samples.

To update the parameter \( t \) in the \( k + 1 \) -th iteration, we use the sign of the gradient with a random magnitude as follows.

\[ t_{k+1} = t_{k} - \alpha \gamma \left| \frac{\partial E}{\partial t_{k}} \right| \]  

(B2)

where \( \alpha \) is a random number in the range \( (0, 1) \), \( \gamma \) is the step size, \( t_{k} \) and \( t_{k+1} \) are the values for variational parameter \( t \) at the \( k \)-th and \( k+1 \)-th iteration. In practice, we choose \( \gamma = 0.001 \), weights and bias’ of the neural network are initialized from uniform distribution in the range of \((-0.005, 0.005)\).

Appendix C: Backward propagation of neural network backflow

From the optimization scheme, it is clear that we need to compute \( \frac{\partial \psi}{\partial t} \). In this section, we give the details on how to compute this quantity by backward propagation.

Consider backward propagation in a neural network with \( N \) layers. Denote the value in each layer by a set of vectors \( a^{0}, a^{1}, ..., a^{N-1} \). Denote the value before activation in each layer (counting from the 2nd layer) by
a set of vectors $z^1, z^2, ..., z^{N-1}$. Denote the activation function in each layer (counting from the 2nd layer) by a set of functions $f_1, f_2, ..., f_{N-1}$. Denote the weights by a set of weights (counting from the 2nd layer) by a set of matrix $w^1, w^2, ..., w^{N-1}$ and the bias by a set of vectors by a set of vector $b^1, b^2, ..., b^{N-1}$. Then $a^0$ is the input configuration, for $1 < l \leq N - 1$, forward propagation reads

$$z^l = w^l a^{l-1} + b^l \quad \text{(C1)}$$

$$a^l = f_l(z^l) \quad \text{(C2)}$$

To calculate derivative, we use backward propagation. For the i-th output in the final layer, denote the error of each layer (counting from the 2nd layer) with respect to this output by a set of vectors $i^1, i^2, ..., i^{N-1}$. Set $i^N = f'_N(z^N_{i-1})$. For $1 \leq l \leq N - 1$, backward propagation reads

$$i^l = (((w^l)T i^l) * f'_{l-1}(z^{l-1}) \quad \text{(C3)}$$

$$\frac{\partial a^N}{\partial p} = i^l \quad \text{(C4)}$$

$$\frac{\partial a^N}{\partial u^l_{pq}} = a^{l-1} \otimes i^l \quad \text{(C5)}$$

where $\otimes$ is the element-wise multiplication and the last equation uses outer product $\otimes$.

To transfer backward propagation to $\frac{1}{\psi} \frac{\partial \psi}{\partial t}$, we should view it as a special mapping on top of $a^{N-1}$. Therefore, we only need to choose a different $i^N$ and the rest will be the same as above. First, we consider the Slater-Detenninant type neural network backflow.

$$\frac{1}{\psi_{SD}} \frac{\partial \psi_{SD}(r)}{\partial t} = \frac{1}{\det[M_{SD,\perp}]} \frac{\partial \det[M_{SD,\perp}]}{\partial t} + \frac{1}{\det[M_{SD,\perp}]} \frac{\partial \det[M_{SD,\perp}]}{\partial t} \quad \text{(C6)}$$

where $M_{SD,\sigma} = \phi_{k\sigma}^b (r_{i\sigma})$, $t$ is any variational parameter $\{w^l_{pq}, b^l\}$, Under the Einstein notation, the chain rule gives rise to

$$\frac{1}{\det[M_{SD,\sigma}]} \frac{\partial \det[M_{SD,\sigma}]}{\partial t} = \frac{1}{\det[M_{SD,\sigma}]} \frac{\partial \det[M_{SD,\sigma}]}{\partial \phi_{k\sigma}^b (r_{i\sigma})} \frac{\partial \phi_{k\sigma}^b (r_{i\sigma})}{\partial t} \quad \text{(C7)}$$

$$= tr((M_{SD,\sigma})^{-1} \frac{\partial \det[M_{SD,\sigma}]}{\partial \phi_{k\sigma}^b (r_{i\sigma})} \frac{\partial \phi_{k\sigma}^b (r_{i\sigma})}{\partial t}) \quad \text{(C8)}$$

$$= (M_{SD,\sigma})^{-1} \frac{\partial \phi_{k\sigma}^b (r_{i\sigma})}{\partial t} \quad \text{(C9)}$$

For $\Psi_{SN}$, we have

$$\frac{1}{\det[M_{SD,\sigma}]} \frac{\partial \det[M_{SD,\sigma}]}{\partial t} = (M_{SD,\sigma})^{-1} \frac{\partial \phi_{k\sigma}^b (r_{i\sigma})}{\partial \psi_{ij,\sigma}^N (r_{i\sigma})} \frac{\partial \psi_{ij,\sigma}^N (r_{i\sigma})}{\partial t} \quad \text{(C10)}$$

$$= (M_{SD,\sigma})^{-1} \frac{\partial \phi_{k\sigma}^b (r_{i\sigma})}{\partial t} \quad \text{(C11)}$$

Therefore, we set $i^N = (M_{SD,\sigma})^{-1} f'_N(z^N_{i-1})$ and perform the backward propagation. Notice that we use a matrix index $ki$ for simplicity here. In practice, a matrix will be reshaped into an array for computation.

For $\Psi_{SN-b}$, we have

$$\frac{1}{\psi_{BDG}} \frac{\partial \psi_{BDG}(r)}{\partial t} = \frac{1}{\det[\Phi]} \frac{\partial \det[\Phi]}{\partial t} \quad \text{(C12)}$$

where $\Phi_{ij} = \sum_{k,l}^N \phi_{k\sigma}^b (r_{i\sigma}) S_{kl} \phi_{l\tau}^b (r_{j\tau})$, $t$ is any variational parameter $\{w^l_{pq}, b^l\}$ of $\alpha_{ij}^N$ and $d_{ij}^N$.

For the case that $t$ is a parameter of $a_{kl}^N_i$, we rewrite $\Phi_{ij} = \sum_{k,l}^N \phi_{k\sigma}^b (r_{i\sigma}) R_{kl}$, where $R_{kl} = \sum_{k,l}^N S_{kl}^N \phi_{l\tau}^b (r_{j\tau})$, $\phi_{k\sigma}^b (r_{i\sigma})$ is given by Eq. (5) and $S_{kl}^N = S_{kl} + d_{kl}^N$. The chain rule gives rise to

$$\frac{1}{\det[\Phi]} \frac{\partial \det[\Phi]}{\partial t} = \frac{1}{\det[\Phi]} \frac{\partial \det[\Phi]}{\partial \phi_{k\sigma}^b (r_{i\sigma})} \frac{\partial \phi_{k\sigma}^b (r_{i\sigma})}{\partial t} \quad \text{(C13)}$$

$$= \frac{1}{\det[\Phi]} \frac{\partial \det[\Phi]}{\partial \phi_{k\sigma}^b (r_{i\sigma})} \frac{\partial \phi_{k\sigma}^b (r_{i\sigma})}{\partial t} \quad \text{(C14)}$$

We then set $i^N = (M_{SD,\sigma})^{-1} f'_N(z^N_{i-1})$ and perform the backward propagation. Notice that we use a matrix index $ij$ for simplicity here. In practice, a matrix will be reshaped into an array for computation.

Next, we consider Bogoliubov de Gennes type neural network backflow wave-functions $\Psi_{PN}$,

$$\frac{1}{\psi_{BDG}(r)} \frac{\partial \psi_{BDG}(r)}{\partial t} = \frac{1}{\det[\Phi]} \frac{\partial \det[\Phi]}{\partial t} \quad \text{(C15)}$$

where $\Phi_{ij} = \sum_{k,l}^N \phi_{k\sigma}^b (r_{i\sigma}) S_{kl} \phi_{l\tau}^b (r_{j\tau})$, $t$ is any variational parameter $\{w^l_{pq}, b^l\}$ of $\alpha_{ij}^N$ and $d_{ij}^N$.

For the case that $t$ is a parameter of $a_{kl}^N_i$, we rewrite $\Phi_{ij} = \sum_{k,l}^N \phi_{k\sigma}^b (r_{i\sigma}) R_{kl}$, where $R_{kl} = \sum_{k,l}^N S_{kl}^N \phi_{l\tau}^b (r_{j\tau})$, $\phi_{k\sigma}^b (r_{i\sigma})$ is given by Eq. (5) and $S_{kl}^N = S_{kl} + d_{kl}^N$. The chain rule gives rise to

$$\frac{1}{\det[\Phi]} \frac{\partial \det[\Phi]}{\partial t} = \frac{1}{\det[\Phi]} \frac{\partial \det[\Phi]}{\partial \phi_{k\sigma}^b (r_{i\sigma})} \frac{\partial \phi_{k\sigma}^b (r_{i\sigma})}{\partial t} \quad \text{(C16)}$$

$$= \frac{1}{\det[\Phi]} \frac{\partial \det[\Phi]}{\partial \phi_{k\sigma}^b (r_{i\sigma})} \frac{\partial \phi_{k\sigma}^b (r_{i\sigma})}{\partial t} \quad \text{(C17)}$$

We then set $i^N = (M_{SD,\sigma})^{-1} f'_N(z^N_{i-1})$ and perform the backward propagation. Notice that we use a matrix index $ij$ for simplicity here. In practice, a matrix will be reshaped into an array for computation.

For $t$ is a parameter of $d_{kl}^N$, similarly we define $Q_{kl} = \sum_{k,l}^N \phi_{k\sigma}^b (r_{i\sigma}) S_{kl}^N$ and then set $i^N = \Phi_{ij}^{-1} Q_{jk} f'_N(z^N_{i-1})$.
\[
\frac{1}{\det[\Phi]} \frac{\partial \det[\Phi]}{\partial t} = \frac{1}{\det[\Phi]} \frac{\partial S_{kl}^{NN}}{\partial d_{kl}} \partial d_{kl} = \frac{1}{\det[\Phi]} \frac{\partial S_{kl}^{NN}}{\partial d_{kl}} \partial d_{kl} = \phi_{kl}^{b}(r_{i,j}) \partial d_{kl} \partial t)
\]

We set \( i \delta_{kl}^{N-1} = \phi_{kl}^{b}(r_{i,j}) (\Phi^{-1})_{ij} \phi_{ij}^{b}(r_{j,i}) f_{N-1}(\varepsilon_{kl}^{N-1}) \) and perform the backward propagation.
