Relationships Between the Dimensions of Resilience and Burnout in Primary School Teachers

M. Inmaculada Vicente de Vera García*a, M. Inés Gabari Gambarte b

Abstract

Education professionals are very prone to burnout. Faced with this psychosocial risk, resilience is advocated as a human condition to remake itself in the face of difficulties. The objective of the study was to analyze the relationships between perceptions of burnout and resilience in a sample of 334 teachers from 35 public Primary School Education centers. The accepting sample was composed of 334 teachers (26.34% of the invited sample). It was a cross-sectional, descriptive and correlational study, which responded to a simple random sampling of 1268 teachers in the 2017/2018 academic year, through voluntary and anonymous participation. The instruments used were the Spanish versions of the Maslach Burnout Inventory-General Survey (MBI-GS) and Connor-Davidson Resilience Scale (CD-RISC). Positive relationships were found between emotional fatigue/exhaustion and depersonalization/cynicism and low levels of resilience, as well as between personal fulfillment/effectiveness and high levels of personal competence, confidence in one’s intuition and positive acceptance of change, dimensions typical of the resilient response. The importance of promoting resilient coping strategies such as positivism, tolerance to frustration, locus of internal control and self-efficacy, which act as dimensions of protection against exhaustion, negative dimension of burnout, emerges.

Keywords: Burnout, Depersonalization, Emotional Tiredness, Resilience, Effectiveness, Positivism, Control Locus, Coping Strategies

Introduction

Education professionals often show loss of emotional resources, mainly caused by the physical, mental, and relational demands of teaching work. The excessive number of students in the classrooms, the excess of tasks to be performed, the temporary pressures and work overload, the lack of support teachers, the inadequacy of schedules, the excessive bureaucracy and the paperwork that derives from it, etc., are related to the emotional fatigue of this group (Longas, Chamarro, Riera, & Cladellas, 2012; Liull, Cerdà, & Brage, 2015; Rodríguez, Sola, & Fernández, 2017; Carlotto & Cámara, 2017). Additionally, the incidence of other external factors of the work environment, derived from the general and specific characteristics of the personality, family circumstances or the private and social life of the teacher, interact with personal resources and can lead to a decrease in their activity labor, mental and physical, giving rise to disorders such as burnout (Justo 2010; López & Extremera, 2017; Burgos, Paris, Salcedo, & Arriagada, 2018).

Maslach (2009) explains the dimensions of burnout with a three-dimensional model, which has the presence of three related but empirically distinct components. Galbán (2018) describes the process of the appearance of Burnout Syndrome: it begins with an imbalance between organizational demands and personal resources caused by emotional exhaustion in the worker; subsequently depersonalization or coping is experienced leading the worker to disappointment and exhaustion; it ends with the low personal accomplishment at work as a result of the inefficiency in facing the different labor stressors.

However, despite the fact that organizational events can be stressful by themselves, some subjects are more vulnerable than others to develop the syndrome (Albar et al., 2004; González, Torres, & Carreres, 2017; Martos et al., 2018). This depends, in part, on the cognitive strategies used to solve problems, the type of professional exercise and the development of resistance or protection dimensions that are linked to individual variables, such as personality type and attributes or features of it (Aldas, 2017; Vargas, Niño, & Acosta, 2017).

There are individual traits such as resilience, self-efficacy, resistance to frustration, locus of control, expectations, etc., that exert a great influence on the evaluation that people make of stressful situations based on the cognitive traits of the personality that, in turn, they condition the type of coping to respond to this stressful situation (Morales, 2017; Noreña, 2018). Among the resources that prevent the development of burnout, resilience stands out, understood as a strength that human beings develop in the face of adversity, can resist stressful events, get rid of it, and even get stronger from experience (Bonanno, 2004). In the educational field, resilience refers to the potential that each person has (teachers/students ...). The authors who explore resilience point out that some of the characteristics of resilient people are related to cognitive flexibility, creative ability, the ability to solve interpersonal problems, the good level of self-concept and the bonds of attachment that have been forged in the childhood (Saavedra & Villalta, 2008; Ornelas, 2016).

Numerous studies corroborate that resilience reduces vulnerability to burnout (Stratta et al., 2013; Efi, 2019), being the ability to cope with stressors one of the keys to resilience. So, the use of constructive coping strategies focused on the problem (such as the search for instrumental social support, positive reinterpretation and acceptance) prevents the development of the syndrome (Medrano, 2017). While the use of passive coping strategies focused on emotion (relief, denial and search for emotional social support) facilitates its appearance (Félix, García, & Mercado, 2018). Burnout appears when coping strategies are more focused on emotion and avoidance. Thus, resilient people maintain control over their work while remaining stable even in the presence of con-
licts, staying involved in the task, seeing obstacles as a chal-

lenge to overcome through greater effort, without developing
burnout (Cruz & Puente, 2017; Serrana, 2018; Vicente de Vera &
Gabari, 2019).

Additionally, some research suggests that positive emotions
undo the physiological effects caused by negative emotions.
They underline the weight that positive emotions such as opti-
mism, assertiveness and self-esteem, among other aspects,
have in the construction of the resilient process (McKergow,
2009; Knowlden, Hackman, & Sharma, 2016; Díaz & Barra,
2017). It has been found that an optimistic attitude towards
challenging situations is related to confidence and persist-
ence in behavior, even if things get difficult (Oriol, Mendoza,
Covarrubias, & Molina, 2017). On the contrary, a pessimistic
attitude makes people manifest doubtful and hesitant (Puli-
do & Herrera, 2018). Therefore, giving a positive meaning to
life events and having a coping style focused on the problem,
helps generate positive emotions when adverse situations are
experienced (Dawson & Pooley, 2013; Martínez & Ruch, 2017;
Alarcón, 2018).

Within the positive personality, another variable that bears
some similarity with the concept of resilience, is the strength
of character or also called resistant personality. People with
this type of personality suffer less work stress and tend to
wear less professionally (González, Pelegrín, & Carballo, 2017).
All this leads to that, if a stressful event occurs, the individual
has more strategies to cushion it and not see it only in the
negative sense, but as a challenge (Vargas et al., 2017; Carrara,
2018).

Also, recent studies assert that resilience improves or main-
tains, among other factors, professional effectiveness (Teje-
dor & Mangas, 2016). On the one hand, because self-effective
people do not usually perceive environmental demands as
stressful and, on the other, because they try harder (Vélez,
López, & González, 2017). In fact, numerous works argue that
burnout occurs as a result of successive crises of effectiveness
(Vallejo, 2017; Dios, Calmaestra, & Rodríguez, 2018). These be-
liefs have shown their predictive potential in the development
of the syndrome. The aforementioned authors explain that an
involved subject, with high levels of control and prepared to
face challenges, that uses the appropriate coping strategies,
performs his work more effectively without giving up the de-
manding tasks. Therefore, the lack of self-confidence in doing
the job well increases the probability of suffering burnout (Lo-
zano & Reyes, 2017; Peña, Raso, & Ferrero, 2018). These be-
liefs have shown their predictive potential in the development
of the syndrome.

Another of the personal variables that the scientific litera-
ture associates with the development of the syndrome is the
control locus (Esteras, Sandín, & Chorot, 2016). People with
internal locus of control have the belief that vital events and
their consequences are controlled by their own decisions and
actions. On the other hand, subjects with an external control
locus are convinced that these events are controlled by ex-
ternal forces, other people, luck or destiny (Vargas, Bríñez,
Segura, & Nieto, 2016). These beliefs are relatively stable and
have important implications for performance and well-being
at work. That is, people with internal locus of control, when
they perceive that they have dominion over situations, have
more favorable expectations of coping and face the problems
by carrying out actions that counteract the effects of adverse
conditions (Torres & Bonilla, 2017). His experience, therefore,
is less threatening to stressors than that of people with locus
of external control, more prone to homelessness, vulnerability
and job dissatisfaction (Islas, Gutiérrez, Castellanos, & Mé-
dez, 2017).

Given the shortage of studies in our study environment at the
primary levels of education, in contrast to the numerous lit-
erature on this subject in other contexts such as Latin Amer-
ica or Portugal, the work that we present below has as main
objective to establish relationships between the dimensions
of burnout and the resilience perceived in a sample of Prima-
ry Education teachers. As a secondary objective, we consider
checking the levels of perceived effectiveness in said group
and its influence against burnout. So, given the individual
differences in the implementation of coping strategies under
threatening or stressful conditions, it is plausible to think that
resilience, as well as perceived self-efficacy, could be consid-
ered as outstanding modulators of teacher welfare.

Method
Design
A transversal design is chosen, within a descriptive and corre-

tional model. The independent variable is belonging to a pri-
mary school teaching group. Dependent variables, perceived
burnout and resilience levels, understood as:

Independent Variable:

Teachers of public Primary School: professionals who provide
training between 6 and 12 years, in centers whose main entity
is the administration, so that access is by opposition and their
status is that of civil servant or aspiring to be.

Dependent Variables

1. Burnout: syndrome of physical and emotional ex-
haustration, which implies the development of negative
attitudes towards work, poor self-concept and loss of
interest in the activities carried out. Three subvaria-
bles:

   a. Exhaustion or emotional fatigue: component of
   individual stress, presence of feelings of weakness
   and exhaustion in the face of work demands, loss
   of vital energy and increasing disproportion be-
   tween the work performed and the fatigue expe-
   rienced.

   b. Cynicism or depersonalization: interpersonal
   context component, negative, insensitive or ex-
   cessively apathetic response to various aspects of
   work, minimization of quality and level of perfor-
   mance.

   c. Efficacy or personal fulfillment: self-assessment
   component, is presented in a reduced way, dimin-
   ished sense of self-efficacy and achievements at
   work, aggravated by lack of resources and lack of
   social support and opportunities to develop pro-
   fessionally. the workers come to have a negative
   consideration of themselves and others.

2. Resilience or positive adaptation to circumstances
of significant adversity: an essential component for
good work performance and a basic element for the
protection of workers’ welfare. Five subvariables or
dimensions: personal competence, self-demand and
tenacity; confidence in one’s intuition and tolerance
of adversity; positive acceptance of change and secure
relationships; control; spiritual influences.

Participants

The initial contact for the field study is carried out through an
interview with the Management Teams of the selected Primary
Education Centers, belonging to the public education network
during the 2017/18 academic year, who value the interest of
the proposal and they contribute to the dissemination of the
Questionnaire among the Cloisters, agreeing:
1. Sampling criteria: voluntary and anonymous participation of teachers, without identification of the educational center.

2. Online mode of data collection with a single shipment.

3. Active link for one month from the individual reception of the email, as latency time to issue the response.

The invited sample was composed of the population of teachers (N= 1268) of Primary School Education. The 14 surveys were excluded because they contain errors. The accepting sample consisted of 334 teachers (26.34%), with the distribution set out below.

### Table 1. Sociodemographic distribution of the accepting sample

| Variables                      | Man | Woman | Total | Percentage |
|--------------------------------|-----|-------|-------|------------|
| Between 22 and 35 years        | 12  | 30    | 42    | 12.57      |
| Between 36 and 45 years        | 44  | 64    | 108   | 32.34      |
| Between 46 and 55 years        | 62  | 68    | 130   | 38.92      |
| Between 56 and 65 years        | 28  | 26    | 54    | 16.17      |
| Less than three years          | 8   | 4     | 12    | 3.59       |
| Three to five years            | 12  | 10    | 22    | 6.59       |
| Five to fifteen years          | 26  | 70    | 96    | 28.74      |
| Fifteen and twenty years       | 28  | 26    | 54    | 16.17      |
| More than twenty years         | 78  | 72    | 150   | 44.91      |
| Official                       | 104 | 132   | 236   | 70.66      |
| Hired                          | 16  | 20    | 36    | 10.78      |
| Interim                        | 24  | 32    | 56    | 16.77      |
| Substitute                     | 2   | 4     | 6     | 1.79       |
| Married or living as a couple  | 108 | 138   | 246   | 73.65      |
| Single                         | 22  | 20    | 42    | 12.57      |
| Others                         | 4   | 10    | 14    | 4.20       |
| (Empty)                        | 12  | 20    | 32    | 9.58       |
| No son                         | 44  | 68    | 112   | 33.53      |
| A son                          | 30  | 44    | 74    | 22.15      |
| Two children                   | 56  | 64    | 120   | 35.93      |
| Three children                 | 14  | 10    | 24    | 7.19       |
| More than three children       | 2   | 2     | 4     | 1.20       |

The distribution of the accepting sample was: 188 women (56.29%) and 146 men (43.71%). The highest percentage accumulated was between 46 and 55 years (38.92%). Teaching experience of more than twenty years (44.91%). A high percentage (70.66%) were civil servants. Also, 73.65% of teachers were married or living as a couple. As for the offspring, he highlighted the participation of teachers with children. 66.47% of the teaching staff had a child.

### Instruments

Prior agreement with the Directors of the schools, the information collection instrument used was a single online questionnaire of 46 items with a Likert response with five levels of response, with Cronbach’s a reliability of .815, which allowed us to state that the collected data responded to the intended values, combining:

1. The MBI-GS General Services Burnout Inventory (Shauffeli et al., 1996) in the Spanish adaptation of Salanova, Schaufeli, Llorens, Peiró and Grau (2000). The 15 items of the questionnaire were distributed on three scales: Exhaustion, Cynicism and Efficiency. High scores in Exhaustion and Cynicism and low Efficiency scores mean “more burned by work.” In the original version of the MBI-GS, its authors find Cronbach’s alpha coefficients ranging from .84 to .90 for Exhaustion, from .74 to .84 for Cynicism, and from .70 to .78 for Professional Efficacy. In its adaptation to Spanish, the reliability values of the scales according to Cronbach’s alpha are .83 for exhaustion .73 for cynicism and .81 for professional effectiveness.

2. The Connor-Davidson Resilience Scale Inventory (CD-RISC) prepared by Connor and Davidson (2003) based on previous work by Kobasa (1979), Rutter (1985) and Lyons (1991). The CD-RISC consists of a total of 25 items distributed in five dimensions that we have named:

- **CAT**: Personal competence, Self-demand and Tenacity (8 items),
- **CTF**: Confidence in your own intuition, Tolerance to negative effects and Strength against stress (7 items),
- **ARS**: Positive acceptance of change and Secure Relationships (5 items),
- **CON**: Control (3 items),
- **IES**: Spiritual Influences (2 items).

The scale is classified according to how the subject has felt during the last month. The total score ranges from 0 to 100 and the highest scores reflect greater resilience. The original version has good properties, with a Cronbach’s alpha of .89 (general population) and a test-retest reliability of .87.

Likewise, 4 questions collected information on sociodemographic variables: sex, age range, marital status and number of children, and 2 other questions, on socio-labor variables of the teacher’s job: seniority, stability (hired/am official/a, interim or substitute). It was decided not to request the identification of the workplace to avoid a decrease in the level of response, traditionally low on these issues.

### Process

The management teams of the educational centers were contacted by telephone requesting their collaboration to disseminate the questionnaire among teachers via email. A unique questionnaire was designed, and all invited teachers were sent along with the cover letter ensuring anonymity, as well as explaining the objective that was intended to be obtained from data collection. A response receipt period of one month was established. A previous analysis was performed to rule out incomplete or erroneous questionnaires. Teachers participated voluntarily. All terms of the ethical guidelines of the Declaration of Helsinki (AMM, 2000) were respected at all times.

### Analysis of Data

Descriptive statistics were made to obtain the sociodemographic data of the sample and the different variables studied. Then Spearman correlations (values of p > .20) were made between the three dimensions of burnout (exhaustion, cynicism and efficacy) and the five dimensions of resilience (personal competence, self-demand and tenacity; confidence in one’s own intuition and tolerance to adversity; positive acceptance of change and secure relationships; control; spiritual influences), which were processed and analyzed using v22.0 of the IBM SPSS statistical package.
Significance was set at $p < .01$ and a 99% confidence level was taken into account for all operations.

**Results**

The highest score of the components of the burnout scale was obtained in Personal/Professional Efficacy with a mean of 5.56 ($sd = .83$), followed by Cynicism with a mean of 3.41 ($sd = .94$) and for Emotional Exhaustion with a mean of 3.11 ($sd = 1.25$).

Overall, low burnout rates (percentile < 25) were found in the group of participating subjects. Four subjects who indicated burnout were identified (2.40% of the sample), diagnosed with high exhaustion and cynicism and low efficacy. There were also 14 cases (7.18% of the sample) in which high depletion and cynicism were found with normal efficacy that led us to suspect that there could be more cases (see Table 2).

### Table 2. Evaluation of burnout in Primary School teachers (Spain) 2017/18 academic year

| Burnout cases | n | Percentage | Burnout index |
|---------------|---|------------|---------------|
| Burnout syndrome | 4 | 2.40 | high |
| No burnout effectively < 4 | 12 | 7.18 | under |
| No burnout with exhaustion > 4 | 32 | 19.16 | midle |
| No burnout with cynicism > 5 and exhaustion > 4 | 18 | 10.78 | midle |
| No burnout with exhaustion > 5 | 14 | 8.38 | midle |

Regarding the highest means of the components of the resilience scale, they were obtained in the CTF Dimension: Confidence in one’s own intuition, tolerance for negative effects and tenacity, with an average of 2.91 ($sd = .65$); The CAT Dimension followed: Personal competence, self-demand and tenacity, with an average of 2.8 ($sd = 1.35$); Subsequently, the ARS Dimension: Positive acceptance of change and safe relations, with an average of 2.45 ($sd = 1.35$) and, finally, the CON Dimension: Control Dimension, with an average of 2.37 ($sd = .66$).

The score of the CD-RISC items was classified as low resilience (first quartile), moderate resilience (second and third quartile) and high resilience (fourth quartile). Given that certain mental problems such as depression and a high perception of stress are associated with less resilience (Connor & Davidson, 2003) and high levels of resilience are associated with better mental health conditions (Baek, Lee, Joo, Lee, & Choi, 2010), a total of 44 participants (26.34%) were positioned in the second and third quartiles. So, the participating teachers were in the medium category of resilience index. Table 3 shows the results of the sample in relation to the various Resilience Dimensions.

### Table 3. Resilience assessment in Primary Education teachers (Spain) 2017/18 academic year

| Resilience factors | Results in each factor |
|--------------------|------------------------|
| Factor I: personal competence, self-demand and tenacity | 182 (54.49%) |
| Factor II: confidence in one’s own intuition, tolerance to negative effects and strength against stress | 176 (52.69%) |
| Factor III: positive acceptance of change and safe relationships | 180 (53.89%) |
| Factor IV: control | 168 (50.30%) |
| Factor V: spiritual influences | 176 (52.69%) |

The correlation between burnout and resilience levels collected in this study is shown in Table 4.

The data reported in this study reflected the belonging of the sample to an experienced group, highlighting the low participation of the novice teaching staff with and eventual contract against the official teaching staff that was more collaborative. Likewise, he highlighted the majority participation by women, as well as married teachers and children. Some authors, such as Albar et al. (2004) argue that having children works as a dimension of protection against the syndrome. These authors affirm that this is related to the emotional support received from the family.

The response rate found is an attitude that reflects fear or lack of interest to evidence issues related to burnout in this group and, in turn, may be the reason why it is evidenced by the number of confirmed burnout cases. Authors such as Longes et al. (2012) obtained similar results to those found in this study in an investigation with teachers in Catalonia.

Regarding the levels of resilience, it seems that it tends to develop more in women than in men, an aspect that may be at the base of their coping with adversities in the workplace, inherent in teaching work in the primary stage. In this context, Stratta et al. (2013) compared levels of resilience, finding significant differences in the sources of resilience between men and women, being higher in women, as was the case in this study. Serrano (2018) in an investigation with triathletes, reported that women turn out to be more resistant than men, although the author explains that these differences are not statistically significant.

Likewise, it was the married or living couple professors who scored the highest in resilience compared to the single. Although authors like Justo (2010), confirm that the fact that family problems occur that are distorting the normal functioning of the dynamics of the home, predisposes the person to suffer burnout.

With respect to the dimensions of burnout, the Emotional Exhaustion dimension directly and positively correlated with

### Table 4. Correlation between Burnout Dimensions with Resilience dimensions.

| Dimensions | Exhaustion | Cynism | Effectiveness |
|------------|------------|--------|--------------|
| CAT        | .37**      | .20**  | .33**        |
| CTF        | .30**      | .34**  | .56**        |
| ARS        | .32**      | .19**  | .19**        |
| CON        | .50**      | .26**  | .54**        |
| IES        | .58**      | .48**  | .31**        |

*The correlation is significant at level .01 (bilaterally). The correlation is significant at level .05 (bilaterally).*
Cynicism ($r = .58, p < .01$) and with some statements pertaining to the Dimensions of the Resilience scale that contained negative aspects of work ($r = .37, p < .01$; $r = .38, p < .01$; $r = .61, p < .01$ and $r = .58, p < .01$). In contrast, the correlation was negative with the Effectiveness dimension ($r = -.24, p < .01$). In this order of things, the loss of emotional resources caused by the physical, mental, emotional and relational demands of the teaching work (the excessive number of students in the classrooms, the excess of tasks to be performed, the temporary pressures and the overload at work, the lack of support teachers, the inadequacy of schedules, the excessive bureaucracy and the paperwork that derives from it, etc.) in interaction with individual resources, can negatively impact their health and decrease the teacher feelings of self-efficacy. The results obtained in this dimension, confirm the studies of authors such as López and Extremena (2017), Rodríguez et al. (2017) and Galbán (2018) who state that when there are high demands and poor resources at work, this makes it difficult to achieve objectives, feelings of self-efficacy diminish in the teacher and, over time, give rise to the syndrome of burning by work or burnout; that is, emotional exhaustion, cynicism and personal/professional inefficiency.

The Cynicism dimension obtained a direct and positive correlation with the emotional exhaustion dimension ($r = .58, p < .01$) and with statements belonging to the dimensions of the resilience scale that contained negative aspects of the work ($r = .30, p < .01$; $r = .36, p < .05$; $r = .29, p < .01$; $r = .47, p < .01$; $r = .48, p < .01$). On the contrary, it correlated negatively, with some judgments of the personal/professional effectiveness dimension ($r = -.21, p < .01$). Coinciding with these assessments, Lluli et al. (2015) underline that negative interactions with students (frictions, conflicts and disputes) are related, on the one hand, positively with emotional exhaustion and depersonalization and, on the other, negatively with low personal achievement. The same opinion is expressed by Maslach (2009), Carlitto and Cámara (2017), Burgos et al. (2018) and Vicente de Vera and Gabari (2019), who report that workers with greater emotional fatigue are those who feel more cynicism and less personal fulfillment.

On the other hand, the Personal/Professional Effectiveness dimension was negatively correlated with Emotional Exhaustion ($r = -.24, p < .01$), with Cynicism ($r = -.21, p < .01$) and with some issues of Resilience that referred to some negative aspects of the work ($r = .37, p < .01$; $r = .31, p < .01$). Although it obtained a direct correlation with the positive aspects of the work contained in the Resilience scale ($r = .31, p < .01$). Thus, the positive features of the work, such as: realistic employment objectives, participation in decision-making, autonomy, organizational support, availability of resources, etc., increase the perceived effectiveness of the teacher, which allows him to control the demands and it enables you to believe in your own abilities. Tejedor and Mangas (2016) and Cruz and Puentes (2017) explain that, as self-efficacy decreases, feelings of emotional exhaustion raise burnout to increase. Other authors, such as Peña et al. (2018) report that the subject's perception of feeling effective with the tasks he performs plays a relevant role in the development of the syndrome. They affirm that a subject involved with high levels of control and prepared to face challenges, using appropriate coping strategies, performs his or her work more effectively without surrendering to demanding tasks.

In sum, efficacy beliefs decrease the likelihood of a teacher experiencing stress under certain conditions (Lozano & Reyes, 2017; Vélez et al., 2017). On the contrary, people who judge themselves as ineffective value their own deficiencies more, as well as potential difficulties, so they are more likely to experience stress (Vallejo, 2017; Dios et al., 2018). So, the lack of self-confidence in performing the tasks well increases the probability of suffering burnout.

Regarding the scores reported in the Dimensions of the Resilience scale, the results showed that the CAT dimension (personal confidence, self-demand and tenacity) correlated positively with emotional exhaustion ($r = .37, p < .01$), Cynicism ($r = .30, p < .01$) and with the negative aspects contained in the CTF dimension, ($r = .32, p < .01$), ARS dimension, ($r = .56, p < .01$), CON dimension, ($r = .43, p < .01$) and IES dimension ($r = .50, p < .01$) of the Resilience scale. Instead, it correlated negatively with emotional exhaustion and negative avoidance strategies, and it correlated negatively with emotional avoidance and auto-focalization strategies. On the other hand, Felix et al. (2018) point out that inappropriate strategies, of the escapist type, increase the probability of suffering burnout, as indicated by the correlations of Dimension I that we have just explained. So, when the individual uses coping strategies that are not right to deal with a certain situation, the possibility of suffering burnout increases.

The CTF dimension, confidence in one's intuition, tolerance for negative effects and strength against stress, presented a significant association with the Effectiveness dimension ($r = .31, p < .01$), with the ARS dimension ($r = .19, p < .05$), dimension CON ($r = .08, p < .01$) and dimension IES ($r = .26, p < .01$), of the Resilience scale. On the other hand, the association was negative with emotional exhaustion ($r = -.20, p < .01$) and Cynicism ($r = -.06, p < .05$). Referring to the correlations of this Dimension, Ornelas (2016), González et al. (2017) and Alarcón (2018) emphasize that some people are more resistant to stressors, which allows them to implement coping strategies to overcome the demands that generate stress and allows them to achieve an effective response to restore the balance of situation. They add that this enables them to implement coping strategies to overcome the demands and allows them to achieve an effective response to restore the balance of the situation. On the other hand, Medrano (2017), Noreña (2018) and Martos et al. (2018) confirm that the use of stress coping strategies focused on the problem, such as those found in this component, prevents the development of the syndrome.

The ARS dimension, positive acceptance of the change, obtained a significant association with Efficacy ($r = .34, p < .01$), with the CAT dimension ($r = .56, p < .01$), the CTF dimension, ($r = .19, p < .05$) and IES dimension ($r = .54, p < .01$). The association was negative with the CON dimension ($r = -.41, p < .01$) of the Resilience. In relation to these data, Dawson and Pooley
En el caso de los profesores, la resiliencia puede reducir la vulnerabilidad al burnout. El estudio de Alarcón (2018) muestra que los profesores con resiliencia tienen una mejor capacidad para argumentar sus emociones, superar el riesgo, y aumentar sus habilidades. Se puede concluir que algunas variables personales, como resiliencia y autoeficacia, pueden prevenir el burnout.

En resumen, el perfil de los profesores que enfrentan el burnout es más probable que sean menos resistentes. Los resultados del estudio de Alarcón (2018) muestran que la resiliencia ayuda a enfrentar los desafíos laborales y reduce la vulnerabilidad al burnout. Es importante continuar investigando y desarrollando estrategias de resiliencia en el futuro.
