Abstract

We use the recently constructed solution for marginal deformations by one of the authors, to analytically relate the BCFT modulus ($\lambda_{\text{BCFT}}$) to the coefficient of the boundary marginal field in the solution ($\lambda_{\text{SFT}}$). We explicitly find that the relation is not one to one and the same value of $\lambda_{\text{SFT}}$ corresponds to a pair of different $\lambda_{\text{BCFT}}$'s: a “small” one, and a “large” one. The BCFT moduli space is fully covered, but the coefficient of the marginal field in the solution is not a good global coordinate on such a space.

1 Introduction and Conclusion

Open String Field Theory (OSFT) could provide a complete non-perturbative approach to D-brane physics, once its quantum structure is understood. Still, at the classical level it gives a new perspective and methodology for finding the possible conformal boundary conditions which are consistent with a given bulk two-dimensional CFT. In String Theory language this amounts to the classification of the possible physical D-branes (stable or not) that can be consistently placed in a given closed string background. From the OSFT perspective this means solving the classical equation of motion.

The aim of this paper is to provide exact non-perturbative results on the relation between BCFT marginal parameters and the corresponding parameters in OSFT solutions. Remarkably we now know [1], that given two generic BCFT’s (sharing a common non-compact time-like factor) it is always possible to explicitly construct an analytic solution relating the two backgrounds, by suitably using a pair of boundary condition changing operators with known OPE. However here we would like to study an example which is not so distant to the available Siegel gauge numerical results, where the time-CFT is only excited through the identity and its descendants. For self-local boundary marginal deformations [2], we have an explicit analytic wedge-based solution [3], and this is the solution we wish to study in this note.

Given an open string background BCFT$_0$, there is typically a continuous manifold of equally consistent open string backgrounds, connected to BCFT$_0$, forming a moduli space. Such a moduli space is locally spanned by the VEV of the exactly marginal boundary operators that can be switched on in BCFT$_0$. Because of the linear structure of small fluctuations, it appears natural to parametrize the OSFT solutions for marginal deformations by the coefficient of their marginal field. This quantity is typically called $\lambda_{\text{SFT}}$

$$\Psi_{\text{marg}} = \lambda_{\text{SFT}} cj(0) |0\rangle_{SL(2,R)} + \cdots.$$  \hspace{1cm} (1.1)

On the other hand, the physical trajectory in moduli space has a more natural coordinate $\lambda_{\text{BCFT}}$, or more succinctly $\lambda$, which corresponds to the strength of the (conformal) boundary interaction that one adds to the sigma-model action to describe the new background

$$S_{\text{BCFT}} = S_{\text{BCFT}} + \lambda \int_{\partial M} ds j(s).$$  \hspace{1cm} (1.2)

The relation between $\lambda_{\text{SFT}}$ and $\lambda_{\text{BCFT}}$ triggered a lot of discussions in the last fifteen years [4, 5, 6, 7, 8, 9, 10], especially because of the following long-standing puzzle. Given an exactly marginal field $j(z)$, a one-parameter family of approximate solutions labeled by $\lambda_{\text{SFT}}$ was found in Siegel gauge by Sen and Zwiebach [4]. Evidence was found that this one-parameter family ceases to exist at a finite value of $\lambda_{\text{SFT}}$, posing the question about the ability of OSFT to cover or not the BCFT moduli space. With the advent of the new analytic methods, beginning with [11], new powerful tools have been developed to extract the BCFT data from a given OSFT solution. Notably it has been found how to directly construct the boundary state corresponding to a given solution [12, 13], using a powerful conjecture due to Ellwood [14], which relates simple gauge invariants in OSFT to closed string tadpoles in the new
open string background defined by a given solution. Using Ellwood conjecture, more recent results for
the cosine deformation at the self-dual radius [10], showed that the finite critical value at which the
solutions of [4] truncate, correspond to a finite value of $\lambda_{\text{BCFT}}$, close to the point where the boundary
conditions become Dirichlet. After that no further solutions are found. Where is the missing region
of the BCFT moduli space?

In this note we propose that such an apparent drawback is simply a consequence of the fact that
$\lambda_{\text{SFT}}$ does not globally parameterize OSFT solutions for marginal deformations which, on the other
hand, exist for all physical values of $\lambda_{\text{BCFT}}$. To do so, we derive, in an explicit computable example,
the precise relation between $\lambda_{\text{SFT}}$ and $\lambda_{\text{BCFT}}$, taking advantage of the recently constructed solution
for marginal deformations [3], which is naturally defined in terms of $\lambda_{\text{BCFT}}$. This allows to calculate
$\lambda_{\text{SFT}}$ as a function of $\lambda_{\text{BCFT}}$, by simply computing the coefficient of the marginal field in the solution

$$\lambda_{\text{SFT}} = \langle 0|j_{1c-1c_0}|\Psi(\lambda_{\text{BCFT}}) \rangle = f_{\Psi}(\lambda_{\text{BCFT}}).$$ (1.3)

This computation gives a nice surprise: we find that $\lambda_{\text{SFT}}$, as a function of $\lambda_{\text{BCFT}}$, starts linearly
with unit slope and then, after reaching a maximum, it starts decreasing and it eventually relaxes to
zero for large values of $\lambda_{\text{BCFT}}$, see figure [2]. Therefore, for a given $\lambda_{\text{SFT}}$ there are typically two values
of $\lambda_{\text{BCFT}}$. This is our main result.

The fine details of the function $\lambda_{\text{SFT}}(\lambda)$, including the critical value of $\lambda_{\text{BCFT}}$ at which $\lambda_{\text{SFT}}$ has a
maximum, depend on the gauge freedom in the definition of the OSFT solution, but we find that the
relaxation to zero is generic in the whole gauge orbit which we analyze. It is amazing to realize that
this is precisely the behavior that Zwiebach conjectured many years ago [5], by analyzing a simple field
theory model for tachyon condensation. To further confirm Zwiebach’s hypothesis, we also compute
the coefficient of the zero momentum tachyon. This time, at large $\lambda$, we find that it asymptotes to a
finite positive value. In a particular limit along the gauge orbit the solution localizes to the boundary
of the world-sheet, and the above finite positive value agrees with the tachyon coefficient of the tachyon
vacuum solution $\Psi_{TV} = \frac{1}{1+K} c(1 + K) Bc$ of [15], again in accord with Zwiebach’s picture, see figure [3]. It is tempting to speculate that in fact the whole string field in this limit approaches the tachyon
vacuum $\Psi_{TV}$ as has been shown in the case of light-like rolling tachyon in [16].

Our simple calculation shows that, at least in this particular example, OSFT does cover the
full BCFT moduli space, but such a moduli space cannot be fully described by the coefficient of the
marginal field that generates the deformation. At large BCFT modulus it is not the marginal field that
drives the marginal flow but it is rather the whole string field with all of its higher level components.

An important question is to what degree is this behavior generic. There are other analytic wedge-
based solutions for marginal deformations with singular OPE, which can be constructed systematically
at any order in the marginal parameter [17, 18, 19, 20]. However their intrinsic perturbative nature
is a major obstacle to obtain conclusive results on the issues we are discussing. A non perturbative
treatment of (time-independent) marginal deformations is also clearly provided by the EM solution

\(^3\)See [21] for recent developments in this direction.
It is not difficult to see that for this solution we have the exact relation

\[ \lambda_{SFT}^{(EM)} = \lambda_{BCFT}, \]  

(1.4)

which is in fact common to all SFT solutions which describe marginal deformations with regular OPE \[17, 22, 23\]. The reason for this is that the EM solution in this case describes a marginal deformation \[23\] generated by \( j = \frac{i}{\sqrt{2}} \partial X^0 + j^{(c=25)} \), which has regular OPE with itself by construction. Since time is non-compact, the solution only changes the boundary conditions in the \( c = 25 \) part of the initial BCFT.

That said, it seems plausible that the double-valued dependence on \( \lambda_{SFT} \) we have found is generic in cases where the solution only excites the matter primaries and descendants generated by the repeated OPE’s of the marginal field. It would be very instructive to “experimentally” confirm this expectation by level truncation computation in the Siegel gauge, and to identify the predicted new branch.

## 2 Review of the simple marginal solution

The solution \[3\] can be constructed from any self-local boundary deformation \[2\], generated by a boundary field \( j(x) \) with self-OPE given by \[4\]

\[ j(x)j(0) \sim \frac{1}{x^2} + \text{(reg)}. \]  

(2.5)

Let us quickly review the structure of the solution, details can be found in \[3\]. It is derived from an identity-based solution, discovered years ago by Takahashi and Tanimoto \[24\], which is used here as an elementary identity-like string field in addition to the well known fields \( K, B, c \). Calling \( \Phi \) the TT solution \[24\], and defining as in \[25\]

\[ K' \equiv K + J = Q\Phi \equiv QB + [\Phi, B], \]  

(2.6)

\[ J \equiv [B, \Phi], \]  

(2.7)

where \( [\cdot, \cdot] \) is the graded commutator, the solution \[3\] can be written as

\[ \Psi = \frac{1}{1 + K} \Phi \frac{1}{1 + K'} - Q \left( \frac{1}{1 + K} \Phi \frac{B}{1 + K'} \right). \]  

(2.8)

In the very convenient sliver frame, obtained by mapping the UHP (with coordinate \( w \)) to a semi-infinite cylinder of circumference 2 (with coordinate \( z \)) via the map

\[ z = \frac{2}{\pi} \arctan w, \]  

(2.9)

\[ ^4\text{In } [3] \text{ it was further assumed that the current was not only self-local but also chiral, in the sense of } [2], \text{ so that it was guaranteed to be local with respect to all bulk and boundary fields. This was a technical assumption which allowed to easily construct the fluctuations around the new solution and to show that, for chiral marginal deformations, the Hilbert spaces of the undeformed and deformed theory are isomorphic at the level of the operator algebra. This is not necessarily true for generic self-local boundary deformations.} \]
the TT solution is defined as
\[ \Phi = \int_{-i\infty}^{i\infty} \frac{dz}{2\pi i} \left( f(z) c j(z) + \frac{1}{2} f^2(z) c(z) \right). \] (2.10)

All the degrees of freedom of the function \( f(z) \) are pure gauge except for its zero mode which defines \( \lambda_{\text{BCFT}} \) through the relation
\[ \lambda_{\text{BCFT}} \equiv \lambda = \int_{-i\infty}^{i\infty} \frac{dz}{2\pi i} f(z). \] (2.11)

In the following we will make the dependence on \( \lambda \equiv \lambda_{\text{BCFT}} \) manifest by defining
\[ f(z) \equiv \lambda \bar{f}(z), \] (2.12)
\[ \int_{-i\infty}^{i\infty} \frac{dz}{2\pi i} \bar{f}(z) = 1. \] (2.13)

The current-like string field \( J \) is then given by
\[ J \equiv [B, \Phi] = \int_{-i\infty}^{i\infty} \frac{dz}{2\pi i} \left( f(z) j(z) + \frac{1}{2} f^2(z) \right). \] (2.14)

### 3 \( \lambda_{\text{SFT}} \) vs \( \lambda_{\text{BCFT}} \) and the tachyon

Expanding the solution in the Fock space basis, the first components are the zero momentum tachyon and the marginal field
\[ \Psi = T c_1|0\rangle + \lambda_{\text{SFT}} j_{-1} c_1|0\rangle + \cdots. \] (3.15)

The coefficient of the marginal field is given by
\[
\lambda_{\text{SFT}} = \langle 0| c_{-1} c_0 j_1 |\Psi\rangle = -\frac{1}{2} \int_0^\infty d\ell \int_0^\ell dy \text{Tr} \left[ e^{-K/2} \Phi e^{-(\ell-y+1/2)K} e^{-y(K+J)} \right],
\] (3.16)

while the coefficient of the zero momentum tachyon is
\[
T = \langle 0| c_{-1} c_0 |\Psi\rangle = -\frac{\pi}{2} \int_0^\infty d\ell \int_0^\ell dy \text{Tr} \left[ e^{-K/2} \Phi e^{-(\ell-y+1/2)K} e^{-y(K+J)} \right],
\] (3.17)

Notice that the BRST exact part of the solution (2.8), does not contribute to these coefficients, as well as to any other coefficient of \( c \phi(x)(0)|0\rangle \), where \( \phi \) is a matter primary.
Let us start with the integrand which defines $\lambda_{\text{SFT}}$
\[
\text{Tr} \left[ e^{-K/2} c\partial c j e^{-\left(\ell-y+1/2\right)K} \Phi e^{-y\left(K+J\right)} \right] = \left< c\partial c j \left(\ell + 1/2\right) \Phi(y) e^{-\int_0^y ds J(s)} \right>_{C_{L+1}}.
\]
Here we have defined the world-sheet insertions
\[
\Phi(y) = \int_{-i\infty}^{i\infty} \frac{dz}{2\pi i} \left( f(z) c j(z+y) + \frac{1}{2} f^2(z) c(z+y) \right),
\]
\[
J(s) = \int_{-i\infty}^{i\infty} \frac{dz}{2\pi i} \left( f(z) j(z+s) + \frac{1}{2} f^2(z) \right).
\]
The correlator (3.18) is naturally defined in the cylinder coordinate frame. General correlator of this form on a cylinder of total circumference $L$ is depicted in figure 1.

This correlator can be systematically computed by Wick theorem from the basic current-current correlator
\[
\left< j(z) j(w) \right>_{C_L} = \left( \frac{\pi}{L} \right)^2 \frac{1}{\sin^2 \frac{\pi(z-w)}{L}},
\]
and from the standard ghost correlator
\[
\left< c\partial c(z) c(w) \right>_{C_L} = - \left( \frac{L}{\pi} \right)^2 \sin^2 \frac{\pi(z-w)}{L}.
\]
In particular, Wick theorem implies that we have
\[
\left< e^{-\int_0^y ds J(s)} \right>_{C_L} = \exp \left[ \frac{1}{2} \int_0^y \int_0^y ds_1 ds_2 \left< J(s_1) J(s_2) \right>_{C_L} \right].
\]

---

5See [26] for a general discussion.
In computing the above quadruple integral (two integrals along the boundary and two vertical integrals implicit in the $J$’s) one finds out, by a mechanism analogous to [25], that the contribution from the $f^2$-terms in $J$ precisely cancels with a delta-function contribution coming from the boundary integral of the current correlator. This leaves us with a net result

$$\left< e^{-\int_0^y ds J(s)} \right>_{\mathcal{C}_L} = e^{-\lambda^2 \mathcal{G}_f(y, L)}. \quad (3.24)$$

The function(al) $\mathcal{G}_f$ controls the exponential behavior in $\lambda_{\text{BCFT}} \equiv \lambda$ and it is given by

$$\mathcal{G}_f(y, L) = \int_{-\infty}^{\infty} \frac{d\xi}{2\pi i} \tilde{f} \ast \tilde{f} (\xi) \log \frac{\sin \frac{\pi(y+\xi)}{L}}{\sin \frac{\pi \xi}{L}}, \quad (3.25)$$

$$f \ast f (\xi) \equiv \int_{-\infty}^{\infty} \frac{dz}{2\pi i} \tilde{f}(z - \xi/2) \tilde{f}(z + \xi/2). \quad (3.26)$$

Then, with standard generating function techniques, we can explicitly compute

$$\left< \partial \partial c j(x) \Phi(y) e^{-\int_0^y ds J(s)} \right>_{\mathcal{C}_L} = -\lambda \left( 1 + \lambda^2 \mathcal{F}_f(x, y, L) \right) e^{-\lambda^2 \mathcal{G}_f(y, L)}. \quad (3.27)$$

The $\lambda^2$ contribution in front of the exponential, which we denote $\mathcal{F}_f$, is given as a product of two quantities

$$\mathcal{F}_f(x, y, L) = \mathcal{S}_f(x, y, L) \mathcal{P}_f(x, y, L). \quad (3.28)$$

The first factor accounts for the contraction of $j(x)$, the matter part of the test state, with the exponential interaction and it is given by

$$\mathcal{S}_f(x, y, L) = \frac{L}{\pi \lambda} \left< j(x) \int_0^y ds J(s) \right>_{\mathcal{C}_L} = \int_{-\infty}^{\infty} \frac{dz}{2\pi i} \tilde{f}(z) \left( \cot \frac{\pi(y-x+z)}{L} + \cot \frac{\pi(x-z)}{L} \right). \quad (3.29)$$

The second factor is responsible for the contraction between the current in $\Phi(y)$ and the exponential interaction, as well as the total ghost contribution (which gives an explicit $x$-dependence)

$$\mathcal{P}_f(x, y, L) = \int_{-\infty}^{\infty} \frac{d\xi}{2\pi i} \left[ \tilde{f} \ast \tilde{f}(\xi, x, y, L) \cot \frac{\pi(y-\xi)}{L} + \tilde{f} \circ \tilde{f}(\xi, x, y, L) \cos \frac{\pi \xi}{L} \right], \quad (3.30)$$

$$\tilde{f} \ast \tilde{f}(\xi, x, y, L) \equiv \int_{-\infty}^{\infty} \frac{dz}{2\pi i} \tilde{f}(z - \xi/2) \tilde{f}(z + \xi/2) \sin^2 \frac{\pi(x-y-z+\xi/2)}{L}, \quad (3.31)$$

$$\tilde{f} \circ \tilde{f}(\xi, x, y, L) \equiv \int_{-\infty}^{\infty} \frac{dz}{2\pi i} \tilde{f}(z - \xi/2) \tilde{f}(z + \xi/2) \frac{1}{2} \sin \frac{2\pi(x-y-z)}{L}. \quad (3.32)$$

The second contribution in $\mathcal{P}_f$, controlled by $(f \circ f)$, is a residue of a cancelation between the counterterm in the TT solution $\sim \int \frac{1}{2} f^2(z) c(z+y)$ and a corresponding term from the contraction of $j(z+y)$

---

6A much quicker way to compute this correlator is to see it as $\langle \sigma_L(y) \sigma_R(0) \rangle_{\mathcal{C}_L}$, where the bcc-like operators are given by $\sigma_{L/R}(x) = e^{\mp \lambda \chi_f(x)}$, and use Wick theorem directly in terms of $\chi_f$, see [3] for the precise definitions.
in the TT solution and the exponential interaction. The latter gives rise to a delta function (canceling the TT counter-term) plus a remaining contribution, from which the second term in $\mathcal{P}_f$ originates.\footnote{This can be seen by infinitesimally detaching the TT solution $\Phi$ from the left edge of the exponential interaction.}

The basic correlator for the zero momentum tachyon is given by the simpler expression

$$\left\langle c \partial c(x) \Phi(y)e^{-\int_0^\infty ds J(s)} \right\rangle = -\lambda^2 \mathcal{P}_f(x,y,L) e^{-\lambda^2 \mathcal{G}_f(y,L)}.$$  \hspace{1cm} (3.33)

The marginal and tachyon coefficients are finally given by the $\bar{f}$-dependent functionals

$$\lambda_{\text{SFT}}(\lambda) = \lambda \int_0^\infty d\ell \ell e^{-\ell \int_0^1 d\hat{y} \left(1 + \lambda^2 \mathcal{F}_f(\ell + 1/2, \ell \hat{y}, \ell + 1)\right) e^{-\lambda^2 \mathcal{G}_f(\ell \hat{y}, \ell + 1)}},$$ \hspace{1cm} (3.34)

$$T(\lambda) = \frac{\lambda^2}{2} \int_0^\infty d\ell \ell (\ell + 1) e^{-\ell \int_0^1 d\hat{y} \mathcal{P}_f(\ell + 1/2, \ell \hat{y}, \ell + 1) e^{-\lambda^2 \mathcal{G}_f(\ell \hat{y}, \ell + 1)}},$$ \hspace{1cm} (3.35)

where we introduced $\hat{y} = y/\ell$ for later convenience. Notice that the $\lambda$-dependence is fully manifest.

### 3.1 Explicit results

To continue further we choose a family of functions $f_t(z)$, given by the gaussians \footnote{As shown in \cite{3} the $t$ dependence is just an $L^{-}$ reparametrisation of the TT solution $\Phi$ and it is thus a gauge redundancy. For very large $t$ the gaussian becomes a delta function which localizes the exponential interaction to the boundary, providing a regularization of contact term divergences, alternative to the standard one by Recknagel and Schomerus \cite{2}. In our application this choice is particularly fortunate as it allows to perform the convolution-like operations (3.26, 3.31, 3.32) analytically. In particular we have}

$$f_t(z) \equiv 2\lambda \sqrt{\pi} t e^{(tz)^2}. \hspace{1cm} (3.36)$$

As shown in \cite{3} the $t$ dependence is just an $L^{-}$ reparametrisation of the TT solution $\Phi$ and it is thus a gauge redundancy. For very large $t$ the gaussian becomes a delta function which localizes the exponential interaction to the boundary, providing a regularization of contact term divergences, alternative to the standard one by Recknagel and Schomerus \cite{2}. In our application this choice is particularly fortunate as it allows to perform the convolution-like operations (3.26, 3.31, 3.32) analytically. In particular we have

$$f_t * f_t(\xi) = \lambda^2 \sqrt{2\pi} t e^{(\xi)^2},$$ \hspace{1cm} (3.37)

$$f_t * f_t(\xi, x, y, L) = \lambda^2 \sqrt{\frac{\pi}{2}} t e^{(\xi)^2} \left(1 - e^{\frac{x^2}{2L^2}} \cos \left[\frac{2\pi(x - y + \xi)}{L}\right]\right),$$ \hspace{1cm} (3.38)

$$f_t \odot f_t(\xi, x, y, L) = \lambda^2 \sqrt{\frac{\pi}{2}} t e^{(\xi)^2} e^{\frac{x^2}{2L^2}} \sin \frac{2\pi(x - y)}{L}.$$ \hspace{1cm} (3.39)

The remaining integrations are performed numerically, except for the second term in $\mathcal{P}_f$ (3.30) which can be computed analytically

$$\int_{-i\infty}^{i\infty} \frac{d\xi}{2\pi i} \bar{f} \odot \bar{f}(\xi, x, y, L) \cos \frac{\pi \xi}{L} = \frac{\lambda^2}{2} e^{\frac{x^2}{2L^2}} \sin \frac{2\pi(x - y)}{L}.$$ \hspace{1cm} (3.40)

In figure \cite{2} we plot the marginal coefficient as a function of $\lambda$ for a selection of $t$ parameters. The plots reveal a clear peak in $\lambda_{\text{SFT}}$ and as a result for a given $\lambda_{\text{SFT}}$ we find two corresponding values of
\[ \lambda_{BCFT} = \frac{1}{2\sqrt{2}} \]

\[ \lambda_{SFT} \]

\[ \lambda_{BCFT} \]

\[ \lambda_{SFT} \]

\[ t = 2 \]

\[ t = 3 \]

\[ t = 5 \]

\[ t = 10 \]

\[ t = 100 \]

\[ t = 200 \]

\[ t = 300 \]

\[ t = 500 \]

Figure 2: Plot of \( \lambda_{SFT}(\lambda) \) for a set of parameters \( t \) in the function \( f_t(z) \) entering the definition of the TT solution: \( O(1) \) values of the gauge parameter \( t \) are shown on the left and larger values on the right. Dotted curves are extrapolations (for large \( t \) the numerical integrations are very slow so we selected a region around the peak). To set the scale: the vertical dashed line corresponds to \( \lambda_{BCFT} = \frac{1}{2\sqrt{2}} \) which, for the marginal deformation generated by \( j(s) = \sqrt{2}\cos X(s) \), is the point where the initial Neumann boundary condition becomes Dirichlet. The Siegel gauge solution stops existing approximately at this point [10].

\( \lambda_{BCFT} \). Had we included smaller values of \( t \) (corresponding to less localized gaussians) we would have seen \( \lambda_{SFT} \) crossing the horizontal axis and approaching zero from below. This implies, in this smaller \( t \) regime, a quadruple degeneracy for sufficiently small \( \lambda_{SFT} \), taking into account also negative values of \( \lambda_{BCFT} \). For \( t \gtrsim 2 \) the degeneracy is only two-fold and this is the region that we show in the plots. From the plots it is also quite evident that at large \( \lambda \) the marginal field relaxes to zero. Notice that the possibility that the maximum of \( \lambda_{SFT} \) is reached at the point \( \lambda_{BCFT} = \frac{1}{2\sqrt{2}} \) (which is approximately what happens in Siegel gauge [10], and for a range of \( t \) parameters also here) is excluded to be true in general. The position of the maximum is not gauge invariant.

In figure 3 we plot the tachyon coefficient. Notice that for large \( \lambda \) it tends to a positive constant. This positive constant, for large \( t \), approaches the coefficient of the simple tachyon vacuum \( \Psi_{TV} = \frac{1}{1 + R} c(1 + K) Bc \) of [15]

\[ T_{\text{simple}} = \frac{1}{4 \pi} \int_0^\infty d\ell \ e^{-\ell} (\ell + 1)^2 \left( 1 - \cos \frac{\pi}{\ell + 1} \right) = 0.284394. \] (3.41)

### 3.2 Asymptotics for large \( \lambda \) and large \( t \)

The numerical integrations we have just performed suggest that something non-trivial must happen for large \( \lambda \) since the marginal coefficient relaxes to zero, while the tachyon coefficient to a positive constant. Naively one would think that both quantities should relax to zero because of the exponential suppression \( \sim e^{-\lambda^2 G_f} \), but evidently this is not the case. To understand what happens in the \( \lambda \to \infty \) limit, we first notice that

\[ \lim_{\lambda \to \infty} \lambda^2 e^{-\lambda^2 G_f(\ell \hat{y}, \ell + 1)} = \delta \left[ G_f(\ell \hat{y}, \ell + 1) \right]. \] (3.42)
This is the leading term in the asymptotic distributional expansion

\[
\lambda^2 e^{-\lambda^2 f(y)} = \sum_{n=0}^{N} (-1)^n \frac{\delta^{(n)}[f(y)]}{\lambda^{2n}} + O(\lambda^{-2N-2}).
\]  

(3.43)

Using the explicit definitions \((3.25, 3.26, 3.37)\) this further simplifies to

\[
\lambda^2 e^{-\lambda^2 g_f(\ell, \ell+1)} = \sqrt{\frac{2}{\pi \ell t}} \delta(\hat{y}) + O \left( \frac{1}{\lambda^2} \right).
\]  

(3.44)

This essentially means that the large \(\lambda\) behavior is dominated by surfaces where the deformed region has zero width and the exponential term attains unit value

\[
e^{-\lambda^2 g_f(y \to 0, L)} = 1.
\]

Therefore the string field coefficients for large \(\lambda\) are not necessarily exponentially suppressed. Let us start by looking at the fate of the tachyon coefficient. Using the above results we get

\[
\lim_{\lambda \to \infty} T(\lambda) = \frac{1}{2t} \sqrt{\frac{2}{\pi}} \int_0^\infty d\ell e^{-\ell (\ell + 1)} \left[ \lim_{\hat{y} \to 0} \mathcal{P}_f (\ell + 1/2, \ell \hat{y}, \ell + 1) \right].
\]  

(3.45)

We can further compute

\[
\lim_{\hat{y} \to 0} \mathcal{P}_f (\ell + 1/2, \ell \hat{y}, \ell + 1) = t \sqrt{\frac{\pi}{2}} \frac{(\ell + 1)}{2\pi} \left( 1 - e^{\frac{-\pi^2}{2(\ell + 1)^2\pi^2}} \cos \frac{\pi}{\ell + 1} \right).
\]  

(3.46)

The large \(\lambda\) asymptotic value for the tachyon coefficient is thus given by

\[
T(\lambda) = \frac{1}{4\pi} \int_0^\infty d\ell e^{-\ell (\ell + 1)^2} \left( 1 - e^{\frac{-\pi^2}{2(\ell + 1)^2\pi^2}} \cos \frac{\pi}{\ell + 1} \right) + O \left( \frac{1}{\lambda^2} \right),
\]  

(3.47)
and it is shown in figure 3.

Notice that for very large $t$ this quickly approaches the tachyon coefficient (3.41) of the simple tachyon vacuum. On the contrary, as expected, the $t \to 0$ limit is very badly behaved which is related to the identity singularities of the TT solution [3].

If we apply the same analysis to $\lambda_{SFT}$ we now find

$$\lambda_{SFT}(\lambda) = \sqrt{\frac{2\lambda}{\pi t}} \int_0^\infty d\ell e^{-\ell} \left[ \lim_{\hat{y} \to 0} S_f(\ell + 1/2, \ell \hat{y}, \ell + 1) + \mathcal{P}_f(\ell + 1/2, \ell \hat{y}, \ell + 1) \right] + O\left(\frac{1}{\lambda}\right). \tag{3.48}$$

Now the $\hat{y} \to 0$ limit also includes $S_f$ (3.29), and it is not difficult to see that the limit vanishes as it is the difference of two identical converging integrals. Therefore the $\lambda$-coefficient in the asymptotic expansion vanishes and we are left with

$$\lambda_{SFT}(\lambda) = O\left(\frac{1}{\lambda}\right), \quad \lambda \to \infty, \tag{3.49}$$

which is indeed much milder than the naively expected exponential suppression.

At last we would like to extract the $t \to \infty$ limit of our solution at fixed $\lambda$, where the exponential interaction $e^{-\int ds J(s)}$ localizes to the boundary. In order to do so we should note that the $G$ function (3.25), diverges for large $t$ unless $\hat{y} = 0$ (which corresponds to a vanishing-width deformed region). To extract the relevant behavior in this limit it is useful to use the asymptotic formula

$$\int_{-\infty}^\infty d\xi e^{-b\xi^2} \ln \left(1 + \frac{a^2}{\sinh^2 \omega \xi}\right) \sim \frac{2\pi a}{\omega}, \quad a \to 0, \tag{3.50}$$

which allows to extract the small $\hat{y}$ contribution from $G$

$$G(\ell \hat{y}, \ell + 1) \sim \frac{(\ell + 1)t}{\sqrt{2\pi}} \sin \frac{\pi \hat{y} \ell}{\ell + 1}, \quad \hat{y} \to 0. \tag{3.51}$$

Then, in the $t \to \infty$ limit we get the same localization mechanism (3.42) as in the large $\lambda$ case, where now the role of large $\lambda^2$ is played by large $t$, for fixed $\lambda$

$$e^{-\lambda^2 G(\ell \hat{y}, \ell + 1)} \sim \sqrt{\frac{2}{\pi \lambda^2 \ell \hat{y}}} \delta(\hat{y}). \tag{3.52}$$

Following the same steps as for the $\lambda \to \infty$ case, we now find

$$\lim_{t \to \infty} T(\lambda) = \begin{cases} \frac{1}{4\pi} \int_0^\infty d\ell e^{-\ell}(\ell + 1)^2 \left(1 - \cos \frac{\pi}{\ell + 1}\right) = T_{\text{simple}}, & \lambda \neq 0, \\ 0, & \lambda = 0, \end{cases} \tag{3.53}$$

$$\lim_{t \to \infty} \lambda_{SFT}(\lambda) = 0. \tag{3.54}$$

\[\text{8If needed, the precise } t\text{-dependent coefficient of } \lambda^{-1} \text{ can be computed by taking into account one subleading correction in (3.43).}\]
It is difficult to directly compare these limits with the data because the numerical integrations are very slow in this region, but we have checked that the height and the position of the peaks in $\lambda_{\text{SFT}}(\lambda, t)$ in figure 2 are nicely fitted by

$$\lambda_{\text{max}}_{\text{SFT}}(t) \sim 0.36 \left(\frac{1}{\ln t}\right)^{0.44},$$  \hfill (3.55)

$$\lambda_{\text{crit}}_{\text{BCFT}}(t) \sim 0.59 \left(\frac{1}{\ln t}\right)^{0.44},$$  \hfill (3.56)

which confirm our analysis for $t \to \infty$.

Acknowledgments

We thank Ted Erler, Matěj Kudrna, Masaki Murata, Yuji Okawa and Barton Zwiebach for discussions. We thank the organizers of “New frontiers in theoretical physics”, Cortona, May 2014 and “String field theory and related aspects”, Trieste, July 2014, where our preliminary results were presented. CM thanks the Academy of Science of Czech Republic for kind hospitality and support during part of this work. The research of CM is funded by a Rita Levi Montalcini grant from the Italian MIUR. The research of MS has been supported by the Grant Agency of the Czech Republic, under the grant 14-31689S.
