ABSTRACT. Suppose given a Galois étale cover $Y \to X$ of proper non-singular curves over an algebraically closed field $k$ of prime characteristic $p$. Let $H$ be its Galois group, and $G$ any finite extension of $H$ by a $p$-group $P$. We give necessary and sufficient conditions on $G$ to be the Galois group of a covering of $X$ dominating $Y \to X$.

1. Introduction

1.1. Main statement. Let $p$ be a prime integer, and $k$ an algebraically closed field of characteristic $p$. In [9], A.Pacheco and K.Stevenson have given necessary and sufficient conditions for an extension $G$ of a $p'$-group by a $p$-group to occur as the Galois group of an étale cover of a given proper, non-singular curve $X$ over $k$. We pursue this work further by solving the case of the extension $G$ of an arbitrary group $H$ (which we suppose of course realized as a Galois group) by a $p$-group $P$.

Thanks to the work of S.Nakajima (see [8]), we can define, for any étale $H$-cover $Y \to X$, a family of integers $\delta_{Y,V}$ parametrized by the set $S_H$ of isomorphism classes of simple $k[H]$-modules. These integers describe the Galois module structure of the space $H^0(Y,\Omega_Y)^s$ of semi-simple differentials on $Y$ in the sense that they are defined by the formula:

$$H^0(Y,\Omega_Y)^s \cong \Omega^2 k \oplus \bigoplus_{V \in S_H} P(V)^{\otimes \delta_{Y,V}}$$

(see §2.2 for a precise definition).

These “Hasse-Witt coefficients” seem to be slightly more convenient invariants for our purposes than the previously used generalized Hasse-Witt invariants (see Remark following definition 2.3). Let $Z \to X$ be an étale $G$-cover dominating the étale $H$-cover $Y \to X$, and $q : G \to H$ the corresponding group extension. We show in part 2 the following formula relating the corresponding Hasse-Witt coefficients:
\[ \forall V \in S_H \quad \delta_{Z,q^*V} + \dim_k H^1(G, q^*V) = \delta_{Y,V} + \dim_k H^1(H,V) \]
(see proposition 2.4).

We then use this result in part 3 to prove an extension of the main theorem of [9]:

**Theorem 1.1.** Let \( k \) be an algebraically closed field of positive characteristic \( p \). Let also \( Y \to X \) be a Galois étale cover of proper non-singular curves over \( k \), with Galois group \( H \). Suppose

\[ 1 \longrightarrow P \longrightarrow G \xrightarrow{q} H \longrightarrow 1 \]

is an exact sequence of finite groups, where \( P \) is a \( p \)-group.

Then the embedding problem

\[ 1 \longrightarrow P \longrightarrow G \xrightarrow{q} H \longrightarrow 1 \]

has a strong solution if and only if for every simple \( k[H] \)-module \( V \) the following inequality holds:

\[ \dim_k H^1(G, q^*V) - \dim_k H^1(H,V) \leq \delta_{Y,V} \]

Here are some indications about the origins of this theorem.

When \( H = 1 \), the above result specialises to the classical Theorem of Shafarevich (see for instance [4]) : a given \( p \)-group \( P \) occurs as the Galois group of an étale cover of \( Y \) if and only if the minimal number of generators of \( P \) is less than the Hasse-Witt invariant of \( Y \).

The first to consider inequalities as in the Theorem seems to be E.Kani in [6], and for this reason we call them the Kani inequalities or the Kani conditions. These were given as necessary conditions for the existence of a tame cover, and since Kani considered differentials instead of semi-simple ones, his inequalities coincide with ours only when the curve \( Y \) is ordinary.

Our main source of inspiration was [9], which we tried to interpret from the “Galois module” point of view. The original problem and the presentation in terms of an embedding problem is due to the authors of that paper. However, the tools employed here are quite different, in particular since we use some basic results of modular representation theory. Moreover, we make a heavy use of the convenient Proposition 2.4, which seems new, and of independant interest. As an application, we define, in paragraph 2.5, a refinement of the notion of ordinariness of a Galois étale cover, which we call \( V \)-ordinariness.

In a last paragraph, we give another proof of Theorem 1.1 in the special case solved in [9], namely when \( H \) is supposed a \( p' \)-group (see Proposition 4.2). This proof is based on the same cohomological argument as the one given in [9], but it uses moreover the existence of an interesting quotient of the fundamental group of \( X \).

1.2. **Acknowledgements.** I would like to thank both M.Emsalem and B.Erez for their support.
2. HASSE-WITT COEFFICIENTS

2.1. Notations.

2.1.1. Curves. In the following we fix an algebraically closed field $k$ of positive characteristic $p$.

The letters $X$, $Y$, ... will denote connected, complete, non-singular curves over $k$.

Let $S$ be an effective divisor on a curve $X$. Then the Cartier operator $C$ acts on the space of global sections of the logarithmic differentials $H^0(X, \omega_X(S))$ (one can define this action directly or as dual of the action of the Frobenius, see [13]). This action is $p^{-1}$-linear. We will call semi-simple logarithmic differentials the subspace

$$H^0(X, \omega_X(S))^\perp := k \otimes_{\mathbb{F}_p} H^0(X, \omega_X(S))^C$$

generated by forms fixed by $C$ of the whole space $H^0(X, \omega_X(S))$ of logarithmic differentials. When $S = 0$, this subspace has dimension $\gamma_X$, the classical Hasse-Witt invariant of the curve $X$. One defines also a natural supplement of $H^0(X, \omega_X(S))^\perp$ in $H^0(X, \omega_X(S))$, the space $H^0(X, \omega_X(S))^n$ of nilpotent differentials (see [13]).

We will denote by $\pi_1(X)$ “the” fundamental group of the curve $X$, without specifying a base point. When considering morphisms between curves and their fundamental groups, we will always suppose that a coherent choice of base points is made.

2.1.2. Representation theory. We also need a few basic notions from module theory over an artinian (non-commutative) ring $A$. All $A$-modules will be implicitly supposed of finite type. We will use these notions for the group ring $A = k[H]$ (sometimes $A = \mathbb{Z}_p[H]$) where $H$ is a finite group whose order is (possibly) divisible by $p$. We refer to [2] for more details.

The letter $k$ will always denote the trivial representation.

Every finitely generated $A$-module $M$ has a well-defined (i.e. unique up to isomorphism) projective cover, which we denote by $P(M) \to M$. This allows us to define $\Omega M := \ker(P(M) \to M)$ and inductively $\Omega^{j+1}M = \Omega(\Omega^jM)$.

When there are several groups acting, we will also use the notations with indices $P_H(M)$ and $\Omega_H M$ to stress the fact that $H$ acts.

We will denote by $S_A$ (or $S_H$ when there is no doubt about the field used) a fixed complete set of representatives of the isomorphism classes of simple $A$-modules.

2.1.3. Warning. We make use of the usual notations and vocabulary of both domains, but this is not without certain ambiguities. For an example, the letter $\Omega$ is used with two different meanings. We must also point out that the word semi-simple is very ambiguous.

For an example we will see that, if $Y$ is a curve acted on by a group $H$, the space of semi-simple differentials on $Y$ is in general not semi-simple as a $k[H]$-module. We hope that this warning and the context will help to give a clear meaning to our assertions.

2.1.4. Profinite groups. An embedding problem is a diagram in the category of profinite groups :

$$\begin{array}{ccc}
1 & \longrightarrow & P \\
\pi & \downarrow & a \\
1 & \longrightarrow & G \\
\downarrow & & \downarrow q \\
1 & \longrightarrow & H \\
\end{array}$$

where the vertical arrow is an epimorphism and the horizontal sequence is exact. It is said to have a weak solution if there exists a continuous homomorphism $\beta : \pi \to G$ lifting $\alpha$, i.e. $q \circ \beta = \alpha$. There is a strong solution if one can choose moreover $\beta$ to be an epimorphism. According to [13], Chapitre I, §3.4, Proposition 16, if $cd_p \pi \leq 1$ and $P$ is a pro-$p$-group, there is always a weak solution.
2.2. Definition.

**Lemma 2.1.** Let Y → X be a Galois étale cover of proper non-singular curves, with Galois group H. Then

(i) For any reduced non-trivial effective divisor S the space \( H^0(Y, \Omega_Y(S))^\ast \) of semi-simple differentials logarithmic along S is projective as a \( k[H] \)-module.

(ii) There is a projective \( k[H] \)-module \( P \), unique up to isomorphism, such that \( H^0(Y, \Omega_Y)^\ast \simeq \Omega_Y^{\delta} \oplus P \)

**Proof.** (i) Let \( P \) be a \( p \)-Sylow of \( H \). According to [3], Theorem 1, applied to the subcover \( Y \rightarrow Y/P \), the space \( H^0(Y, \Omega_Y(S))^\ast \) is \( k[P] \)-free. But this is equivalent to say that this space is \( k[H] \)-projective (this is easily seen using the fact that any \( k[H] \)-module is projective relative to \( P \) [see for an example [3] for relative projectivity]).

(ii) Choose \( S \) to be reduced to an orbit under \( H \). Then the short exact sequence of sheaves

\[
0 \rightarrow H^0(Y, \Omega_Y)^\ast \rightarrow H^0(Y, \Omega_Y(S))^\ast \rightarrow k[H] \rightarrow k \rightarrow 0
\]

(see the proof of [3], Theorem 2 for the fact that nilpotent differentials have trivial residues). In view of (i), it suffices to apply the well-known algebraic lemma comparing this sequence to the beginning of the minimal projective resolution of \( k \), see for instance [3], Proposition 4.

\[ \square \]

Now, using the Krull-Schmidt theorem to decompose \( P \), and the fact that the indecomposable projective \( k[H] \)-modules are exactly the projective covers of the simple \( k[H] \)-modules, we can make the structure of \( H^0(Y, \Omega_Y)^\ast \) more precise :

**Definition 2.2.** Let \( Y \rightarrow X \) be a Galois étale cover with Galois group \( H \) and let \( S_H \) be a set of representatives of the isomorphism classes of simple \( k[H] \)-modules. We define the Hasse-Witt coefficients of the cover as the only non-negative integers \( \delta_{Y,V} \) verifying :

\[
H^0(Y, \Omega_Y)^\ast \simeq \Omega_Y^{\delta} \oplus \bigoplus_{V \in S_H} \emptyset(V)^{\oplus \delta_{Y,V}}
\]

**Remark :** It would be more coherent with previous work on the subject to consider generalized Hasse-Witt invariants defined by \( \gamma_{Y,V} := \delta_{Y,V} \cdot \dim_k \emptyset(V) \). However, since \( \dim_k \emptyset(V) \) is hard to compute in general, and contains no geometric information, we prefer to exclude it from the definition, to concentrate on the computation of \( \delta_{Y,V} \)'s.

2.3. Behaviour under quotient : statement. First we introduce a useful notation.

**Definition 2.3.** If \( M \) is any \( k[H] \)-module of finite type, we define

\[
h^i(H, M) := \dim_k H^i(H, M)
\]

If \( q : G \rightarrow H \) is a group epimorphism and \( M \) is a \( k[H] \)-module, we denote by \( q^*M \) the corresponding inflated \( k[G] \)-module. (We will also use \( M = q_*N \) for \( N = q^*M \).)

**Proposition 2.4.** Let \( Z \rightarrow X \) be a Galois étale cover with Galois group \( G \), and let \( Y \rightarrow X \) be any quotient Galois cover, with Galois group \( H \). Denote by \( q \) the quotient map \( G \rightarrow H \). Then :

\[
\forall V \in S_H \quad \delta_{Z,q^*V} + h^1(G, q^*V) = \delta_{Y,V} + h^1(H, V)
\]

Before giving the proof of Proposition 2.4, we make some remarks, beginning by another useful definition.

**Definition 2.5.** Let \( Y \rightarrow X \) be a Galois \( H \)-cover, \( \pi_1(X) \rightarrow H \) the corresponding group epimorphism, and \( q : G \rightarrow H \) an extension of \( H \). We will say that the pair \( (\pi_1(X) \rightarrow H, G \rightarrow H) \) satisfies the Kani inequalities (or conditions) if and only if :

\[
\forall V \in S_H \quad h^1(G, q^*V) - h^1(H, V) \leq \delta_{Y,V}
\]
Remarks:
1. In the perspective of the proof of Theorem 1.1, it is clear that Proposition 2.4 implies that if the embedding problem of the theorem has a solution, then the Kani inequalities hold for \((\pi_1(X) \to H, G \to H)\).
2. Proposition 2.4 is valid without assuming that the kernel \(P\) of \(q : G \to H\) is a \(p\)-group. However, this hypothesis is sometimes useful. For an example, it implies that the inflation map \(q^* : S_H \to S_G\) is one to one. Indeed, we have:

**Theorem 2.6** (Clifford). If \(P\) is any normal subgroup of \(G\) and \(M\) is a semi-simple \(k[G]\)-module, then \(M|_P\) is a semi-simple \(k[P]\)-module.

(see for instance [1], Chapter I.3, Theorem 4). Moreover, it is well known that if \(P\) is a \(p\)-group, the only simple \(k[P]\)-module is the trivial one. Hence, if we suppose that \(P\) is a \(p\)-group, any simple \(k[G]\)-module is trivial when restricted to \(P\).

We can conclude, with this hypothesis on \(P\), that the Hasse-Witt coefficients of the covers \(Z \to X\) and \(Y \to X\) determine each other.

3. M. Emsalem suggested to us that one can consider more generally tame covers, and that Proposition 2.4 could also hold in this more general setting. We hope to come back to these questions in a subsequent paper.

### 2.4. Behaviour under quotient: proof.

The idea is quite naturally to take the fixed part under the kernel \(P\) of \(q : G \to H\) of the two members of the isomorphism:

\[
H^0(Z, \Omega_Z)^* \simeq \Omega^2_G k \oplus \bigoplus_{U \in S_G} P_G(U) \oplus \delta_{Z,U}
\]

and then use the three following lemmas.

#### 2.4.1. Algebraic part.

In this part we assume only that we have an arbitrary exact sequence of groups:

\[
\begin{array}{ccccccc}
1 & \longrightarrow & P & \overset{r}{\longrightarrow} & G & \overset{q}{\longrightarrow} & H & \longrightarrow 1
\end{array}
\]

**Lemma 2.7.** Let \(U \in S_G\).

\[
q_*(P_G(U)^P) \simeq \begin{cases} 
P_H(V) & \text{if } \exists V \in S_H \text{ such that } U = q^*V \\
0 & \text{else} \end{cases}
\]

**Proof.** The proof is a straightforward computation, using the Krull-Schmidt theorem and three facts:

1. If \(U \in S_G\), then \(\text{soc}(P_G(U)) \simeq U\),
   (see [1], Chapter II.6, Theorem 6, or [2], Theorem 1.6.3);
2. \(q_*(k[G]^P) \simeq k[H]\), so in particular \(q_*(\cdot^P)\) sends projectives to projectives;
3. \(k[G] \simeq \bigoplus_{U \in S_G} P_G(U) \oplus \dim_k U\).

\[\square\]

**Lemma 2.8.**

\[
q_*(|\Omega^2_G|)^P \simeq \Omega^2_H k \oplus \bigoplus_{V \in S_H} P_H(V)^{\oplus h^1(G,q^*V) - h^1(H,V)}
\]

**Proof.** We will suppose that \(p \nmid \# P\), the proof in the opposite case being similar, and in fact easier. Then, as Kani notices ([1], §5, Lemma 2), one can easily show inductively that for all \(i\), the module \(\Omega^i_G k\) is non-projective, and this implies \(H^1(P, \Omega^i_G k) \neq 0\) (see [2], Proposition 3.14.4).

Restricting the exact sequence

\[
\begin{array}{ccccccc}
0 & \longrightarrow & \Omega^i_G k & \longrightarrow & P_G(\Omega^{i-1}_G k) & \longrightarrow & \cdots & \longrightarrow & P_G(\Omega_G k) & \longrightarrow & k & \longrightarrow & 0
\end{array}
\]
to $P$ via $r : P \to G$ (which, in view of $r^*k[G] \simeq k[P]^{\oplus H}$, also sends projectives to projectives) and comparing to the minimal $k[P]$-resolution of the trivial module $k$, we get an isomorphism $r^*(\Omega^*_G k) \simeq \Omega^*_P k \oplus Q$, where $Q$ is a projective $k[P]$-module, and this implies $H^1(P, r^*(\Omega^*_G k)) \simeq H^1(P, \Omega^*_P k)$. So we have shown in particular that for any $i$, we have

$$H^1(P, r^*(\Omega^*_G k))^i \neq 0.$$ 

Now applying the functor $q_* (\mathcal{F})$ to the exact sequence

$$0 \to \Omega G \to P \to k \to 0$$

we get the exact sequence of $k[H]$-modules:

$$0 \to q_* (\Omega G)^i \to q_* (P G)^i \to H^1(P, \Omega G)^i \to 0$$

The $k$-vector-space underlying $H^1(P, \Omega G)^i$ is $H^1(P, r^*(\Omega G)^i) \neq 0$, hence the middle arrow has to be zero, and thanks to Lemma 2.7 it comes: $q_* (\Omega G)^i \simeq q_* (P G)^i \simeq P_H(k)$. We proceed similarly, starting with the sequence

$$0 \to \Omega_G^2 \to P G \to \Omega G \to 0$$

we get the exact sequence of $k[H]$-modules:

$$0 \to q_* (\Omega_G^2)^i \to q_* (P G \Omega G)^i \to H^1(P, \Omega_G^2)^i \to 0$$

We claim that $H^1(P, \Omega_G^2)^i \simeq k$. In fact the underlying $k$-vector-space is $H^1(P, r^*\Omega_G^2 k) \simeq H^1(P, \Omega_G^2 k)$. But the above exact sequence for $G = P$ (hence $H = 1$) shows that $H^1(P, \Omega_G^2 k)$ must be simple, and because there is a surjective $k[H]$-map $P_H(k) \to H^1(P, \Omega_G^2 k)$, it can only be the trivial simple module. From this we deduce, comparing the above exact sequence to the minimal $k[H]$-projective resolution of $k$, that $q_* (\Omega_G^2)^i \simeq \Omega_G^2 k \oplus R$, where $R$ is a projective $k[H]$-module. Now, using Lemma 2.7, and the isomorphism

$$P_G(\Omega G)^i \simeq \bigoplus_{U \in S_G} P_H(U)^{\oplus H(U)}$$

(see [7], Proposition 5), a direct computation in the Grothendieck ring of the finitely-generated $k[H]$-modules shows the equality between classes:

$$[R] = [\bigoplus_{V \in S_H} P_H(V)^{\oplus H(G, q^{-1} V)} - k[H, V]]$$

But since both modules involved are $k[H]$-projective, they have to be isomorphic.

\[\square\]

2.4.2. Geometric part. In this part the hypothesis are those of Proposition 2.4.

Lemma 2.9. The pullback along $Z \to Y$ induces isomorphisms

(i) of $\mathcal{F}_P[H]$-modules:

$$\operatorname{Pic}(Y)[p] \simeq (\operatorname{Pic}(Z)[p])^p$$

(ii) of $k[H]$-modules:

$$H^0(Y, \Omega Y)^i \simeq (H^0(Z, \Omega Z)^i)^p$$

Proof. (i) Since the map $Z \to Y$ commutes with the action of $G$, it is clear that the pullback is equivariant.

The Hochschild-Serre spectral sequence (see for instance [7], Chapter III, Theorem 2.20) for the $P$-Galois cover $Z \to Y$ and the sheaf $\mathcal{G}_m Y = \mathcal{O}_Y$ gives the exact sequence of terms of low degree:

$$0 \to H^1(P, k^*) \to \operatorname{Pic}(Y) \to (\operatorname{Pic}(Z))^p \to H^2(P, k^*)$$
Now since $k$ is of characteristic $p$, raising to the power $p$ induces a group isomorphism

\[ k^* \rightarrow k^* \]

In particular, the groups $H^i(P, k^*)$ have no $p$-torsion and are $p$-divisible, and an immediate diagram chase allows to conclude.

(ii) According to [10], Proposition 10, there is a natural isomorphism

\[ \text{Pic}_0(Y)[p] \simeq H^0(Y, \Omega_Y)^C \]

Indeed, if $L$ is an invertible sheaf on $Y$ such that $L^\otimes p \simeq O_X$, write $L \simeq L_Y(D)$ for a divisor $D$ on $Y$, and let $f$ be a function on $Y$ such that $pD = (f)$. To $L$ we can then associate the form $\omega = df/f$, and this gives the map we were looking for. Thanks to this description, one checks immediately that this map is compatible with the action of $H$, and also with the pull-back along $Z \rightarrow Y$. But then (i) gives

\[ H^0(Y, \Omega_Y)^C \simeq (H^0(Z, \Omega_Z)^C)^p \]

and the lemma follows.

2.5. $V$-ordinariness. This section is not necessary for the proof of Theorem 1.1 but is just an illustration of the usefulness of Proposition 2.4. Recall that a cover $Y \rightarrow X$ is said ordinary if the curve $Y$ is, that is if $\gamma_Y = g_Y$.

Definition 2.10. Let $Y \rightarrow X$ be an étale Galois cover of group $H$ and $V \in \mathcal{S}_H$.

The cover is said $V$-ordinary if $\delta_{Y,V} = \dim V(gx - 1) - h^1(H, V) + h^0(H, V)$.

The link with the classical notion is given by the following lemma.

Lemma 2.11. The cover $Y \rightarrow X$ is ordinary if and only if it is $V$-ordinary for all $V \in \mathcal{S}_H$.

Proof. $Y \rightarrow X$ is ordinary if and only if $H^0(Y, \Omega_Y)^C = H^0(Y, \Omega_Y)$. But [1], Theorem 2, gives that

\[ H^0(Y, \Omega_Y)^C \simeq \Omega^2k \oplus \bigoplus_{V \in \mathcal{S}_H} P(V)^{\oplus \dim V(gx - 1) - h^1(H, V) + h^0(H, V)} \]

and the lemma follows.

It is well known that a Galois étale $p$-cover of an ordinary curve is ordinary (this results from the comparison of the Hurwitz and the Shafarevich formulas). Here is a relative version:

Lemma 2.12. Let $Z \rightarrow X$ and $Y \rightarrow X$ be covers as in Proposition 2.4. Then $Z \rightarrow X$ is $q^*V$-ordinary if and only if $Y \rightarrow X$ is $V$-ordinary.

Proof. This follows immediately from Proposition 2.4.

Remark: This two lemmas suggest a method to show that a cover is ordinary, by using subcovers.

3. Extension of covers

Let $Y \rightarrow X$ be a Galois étale cover of Galois group $H$, and $\pi_1(X) \rightarrow H$ the corresponding group epimorphism. In this section, we show that if the pair $(\pi_1(X) \rightarrow H, G \rightarrow H)$ verifies the Kani inequalities, and the kernel $P$ of $G \rightarrow H$ is a $p$-group, then the corresponding embedding problem has a solution (see Theorem 1.1).

3.1. Reductions. In this section, we give an adaptation of an argument of A.Pacheco and K.Stevenson (see [3]).
3.1.1. Reduction lemma.

Lemma 3.1. Let \( Y \rightarrow X \) be a Galois étale cover of Galois group \( H \), and \( \pi_1(X) \rightarrow H \) the corresponding group epimorphism. Suppose

\[
1 \rightarrow P \rightarrow G \rightarrow H \rightarrow 1
\]

is an exact sequence of finite groups, \( P \) is a \( p \)-group, and \( O \) is a subgroup of \( P \) normal in \( G \). Suppose also that the Kani inequalities hold for \( (\pi_1(X) \rightarrow H, G \rightarrow H) \).

(i) The Kani inequalities hold for \( (\pi_1(X) \rightarrow H, G/O \rightarrow H) \).

(ii) Suppose \( \pi_1(X) \rightarrow G/O \) is a strong solution of the embedding problem

\[
\pi_1(X)
\]

\[
1 \rightarrow P/O \rightarrow G/O \rightarrow H \rightarrow 1
\]

Then the Kani inequalities hold for \( (\pi_1(X) \rightarrow G/O, G \rightarrow G/O) \).

Proof. We make constant use of the argument in the second remark following Definition 2.5: in the situation given, Clifford’s theorem (see Theorem 2.6) ensures that the maps \( q : G \rightarrow H, q : G/O \rightarrow H \) and \( q'' : G \rightarrow G/O \) induce canonical bijections between the sets \( S_H, S_G \), and \( S_{G/O} \).

(i) Let \( V \in S_P \). Note that \( q''((q^*V)^O) = q''(q^*V) = q''V \). The inflation-restriction sequence (see for instance [3] 3.5) for \( q'' : G \rightarrow G/O \) and \( q^*V \) ensures that \( h^1(G/O, q''V) \leq h^1(G, q^*V) \) and (i) follows.

(ii) This is a formal consequence of the remark at the beginning of the proof and of Proposition 2.4. \( \square \)

3.1.2. First reduction. Suppose that Theorem 1.1 holds with the extra hypothesis that \( P \) is abelian \( p \)-elementary. Then we claim the theorem holds in general. This is easily proved by induction on \( N = \log_p \#P \), thanks to Lemma 3.3, applied with \( O = \Phi(P) \), the Frattini subgroup of \( P \). Notice that \( \Phi(P) \) is stable by any automorphism of \( P \), hence in particular normal in \( G \).

Remark: The fact that we allow some \( P \)-part in \( H \) enables us to avoid the use of the argument that the \( p \)-cohomological dimension of \( \pi_1(X) \) is at most 1 (compare with [3]). However, we cannot avoid the use of this argument at a later stage.

3.1.3. Second reduction. Suppose next that Theorem 1.1 holds with the extra hypothesis that \( P \) is abelian \( p \)-elementary, and simple as \( \mathbb{F}_p[H]- \)module. Then we claim the theorem holds with the restricted extra hypothesis that \( P \) is abelian \( p \)-elementary. The proof is the same, by induction on \( \dim_{\mathbb{F}_p} P \), thanks to Lemma 3.3, applied with \( O \) the kernel of \( P \rightarrow Q \), where \( Q \) is any \( \mathbb{F}_p[H] \)-simple quotient of \( P \). As \( H \) acts by conjugation on \( P \), the fact that \( O \) is \( H \)-stable ensures that \( O \) is normal in \( G \).

3.2. Fundamental exact sequence.

3.2.1. Introduction. In the following, the data will be:

1. A Galois \( H \)-cover \( Y \rightarrow X \), or equivalently, a continuous surjective group homomorphism \( \pi_1(X) \rightarrow H \).
2. A simple \( \mathbb{F}_p[H]- \)module of finite type \( P \); i.e. an irreducible representation of \( H \) over \( \mathbb{F}_p \).
3. A group \( G \), extension of \( H \) by the \( \mathbb{F}_p[H]- \)module \( P \) (or equivalently a class \( \alpha \in H^2(H, P) \)), such that the Kani conditions hold for \( (\pi_1(X) \rightarrow H, G \rightarrow H) \).
Of course 2 and 3 are equivalent to the previous data of an exact sequence $1 \to P \to G \to H \to 1$, where $P$ is abelian $p$-elementary, simple as $\mathbb{F}_p[H]$-module, such that the Kani conditions hold for $(\pi_1(X) \to H, G \to H)$.

We split this data in two because 3 appears only at a later stage, and also because we will have to distinguish two cases, depending on whether $\alpha$ is zero or not.

3.2.2. Inflation-restriction sequence for profinite groups. In the next general proposition, we use bold letters to distinguish from our previous notations.

**Definition 3.2.** Let $1 \to F \to G \to H \to 1$ be an exact sequence of profinite groups, $M$ a discrete abelian group endowed with a continuous action of $G$. The transgression morphism is the fourth arrow in the exact sequence of terms of low degree in the Lyndon-Hochschild-Serre spectral sequence:

$$0 \to H^1(H,F) \to H^1(G,M) \to H^1(F,M)^H \to H^2(H,F) \to H^2(G,M)$$

**Proposition 3.3.** Suppose moreover that $F$ acts trivially on $M$. Let $F'$ be the commutator subgroup of $F$, and let $\gamma \in H^2(H,F/F')$ be the class of the extension:

$$1 \to F/F' \to G/F' \to H \to 1$$

Then the transgression $\text{trans} : H^1(F,M)^H \to H^2(H,F)$ is given explicitly by:

$$\forall u \in H^1(F,M)^H = H^0(H,\text{Hom}(F/F',M)) \quad \text{trans}(u) = -\gamma \cup u$$

**Proof.** We refer to [5], Theorem 4 for the case of abstract groups.

**Proposition 3.4.** Let $Y \to X$ be a Galois étale cover with Galois group $H$, and $P$ a simple $\mathbb{F}_p[H]$-module.

(i) The exact sequence of terms of low degree for the spectral sequence of the extension $1 \to \pi_1(Y) \to \pi_1(X) \to H \to 1$ is the following exact sequence of finite-dimensional $\mathbb{F}_p$-vector spaces:

$$0 \to H^1(H, P) \to H^1(\pi_1(X), P) \to \text{Hom}_H(\pi^{ab}_1(Y), P) \to H^2(H, P) \to 0$$

(ii) The transgression map $\text{trans} : \text{Hom}_H(\pi^{ab}_1(Y), P) \to H^2(H, P)$ in the sequence above can be described as follows: let $u \in \text{Hom}_H(\pi^{ab}_1(Y), P)$, $u \neq 0$. Then $u$ corresponds canonically to a Galois cover $Z \to X$ whose Galois group is an extension of $H$ by $F$, and $\text{trans}(u)$ is precisely the opposite of the class of this extension in $H^2(H, P)$.

**Proof.** (i) To show the exactness it suffices, in view of Proposition 3.3, to show that $H^2(\pi_1(X), P) = 0$. But $P$ is killed by $p$, so this equality follows directly from $\text{cd}_p(\pi_1(X)) \leq 1$ (for which we refer to [5], Theorem 5.11). Moreover, the largest $p$-elementary quotient of $\pi^{ab}_1(X)$ is of finite dimension over $\mathbb{F}_p$ (this dimension is nothing else than the Hasse-Witt invariant $\gamma_X$), hence so is $\text{Hom}_H(\pi^{ab}_1(Y), P)$ and the $H^i(H, P)$ are also known to be finite-dimensional over $\mathbb{F}_p$.

(ii) One point here is because $u$ is $H$-equivariant and not equal 0, and $P$ is a simple $\mathbb{F}_p[H]$-module, it has to be surjective. Hence $u$ determines a $P$-Galois cover $Z \to Y$, and because $u$ is $H$-invariant, $\pi_1(Z)$ is in fact normal in $\pi_1(X)$, which means that the composite cover $Z \to X$ is Galois. The last assertion can be deduced from Proposition 3.3 by a direct computation, using the explicit description of cup product of cochains given in [5], Chapter II. §1.

3.2.3. Application to the embedding problem. We see that Proposition 3.4 implies at once that if the group $G$ is a non-trivial extension of $H$ by $P$ (that is, its class $\alpha$ in $H^2(H, P)$ is non zero), then the corresponding embedding problem has a strong solution (i.e. $G$ is the Galois group of a cover of $X$ dominating the $H$-cover $Y \to X$). One can of course also see this quite directly, without using the inflation-restriction sequence, but “only” the inequality $\text{cd}_p(\pi_1(X)) \leq 1$. A rather striking fact is that we do not even use the Kani inequalities here.
So the only thing which remains to be proved to end the proof of Theorem 3.1 is that we can also realize the trivial extension. The Proposition 3.4 implies that it is equivalent to the following inequality:

$$\dim_{\mathbb{F}_p} \text{Hom}_H(\pi_{1}^{ab}(Y), P) > \dim_{\mathbb{F}_p} H^2(H, P)$$

3.3. End of the proof.

3.3.1. Rational representations and base extension.

Lemma 3.5. Let $\mathcal{V}$ a simple $\mathbb{F}_p[H]$-module.

(i) $k \otimes_{\mathbb{F}_p} \mathcal{V}$ is a semi-simple $k[H]$-module.

(ii) $\dim_{\mathbb{F}_p} H^i(H, \mathcal{V}) = \dim_k H^i(k \otimes_{\mathbb{F}_p} \mathcal{V})$

(iii) The multiplicity of a simple $k[H]$-module $\mathcal{V}$ in $k \otimes_{\mathbb{F}_p} \mathcal{V}$ is at most 1.

Proof. (i) There is an obvious epimorphism:

$$k[H] \twoheadrightarrow k \otimes_{\mathbb{F}_p} \mathcal{V} \nearrow \mathbb{F}_p[H]$$

and Wedderburn’s theorem (1.3.5) ensures that this last algebra is semi-simple. This shows that $\text{rad}(k[H]) \subset k \otimes_{\mathbb{F}_p} \mathcal{V}$, and because $\mathcal{V}$ is killed by $\text{rad} \mathbb{F}_p[H]$, the module $k \otimes_{\mathbb{F}_p} \mathcal{V}$ is killed by $\text{rad}(k[H])$, hence is semi-simple as a $k[H]$-module.

(ii) This is true without any assumption on $\mathcal{V}$ because

$$H^i(H, k \otimes_{\mathbb{F}_p} \mathcal{V}) \simeq k \otimes_{\mathbb{F}_p} H^i(H, \mathcal{V})$$

(iii), (iv) The proofs are rather technical, and since these facts are not essential in the proof of Theorem 1.1, we omit them. The idea is to first to reduce to $k = \mathbb{F}_p$, and then use the Galois action on $k \otimes_{\mathbb{F}_p} \mathcal{V}$.

(v) For the same reason, we give no details here, and just point out that the proof uses the fact that we have in reality the equality $\text{rad}(k[H]) = k \otimes_{\mathbb{F}_p} \text{rad} \mathbb{F}_p[H]$, which holds because this last ideal is clearly nilpotent. The idea is to indicate that the invariants employed here are in some sense defined over $\mathbb{F}_p$.

Definition 3.6. Let $\mathcal{V}$ a simple $\mathbb{F}_p[H]$-module.

(i) Let $V \in S_H$. We write $V\mathcal{V}$ to say that $V$ is a summand of $k \otimes_{\mathbb{F}_p} \mathcal{V}$.

(ii) We will denote by $\deg \mathcal{V}$ the number of simple summands of $k \otimes_{\mathbb{F}_p} \mathcal{V}$ in a decomposition into simple $k[H]$-modules.

3.3.2. Conclusion. In view of Lemma 3.5, the two following lemmas end the proof of Theorem 1.1.

Lemma 3.7. Let $V \in S_H$ such that $V/\mathcal{V}$. Then:

$$\dim_{\mathbb{F}_p} \text{Hom}_H(\pi_{1}^{ab}(Y), P) = \deg P \cdot (h^2(H, V) + \delta_{Y,V}) = \dim_{\mathbb{F}_p} H^2(H, P) + \deg P \cdot \delta_{Y,V}$$

Proof. First notice that $\text{Hom}(\pi_{1}^{ab}(Y), P) \simeq \text{Hom}(\pi_{1}(Y), \mathbb{F}_p) \otimes_{\mathbb{F}_p} P$. But then using Artin-Schreier theory we see that:

$$\text{Hom}(\pi_{1}(Y), \mathbb{F}_p) \simeq H^1(Y, \mathbb{F}_p) \simeq H^1(Y, \mathcal{O}_Y)^F \simeq (H^0(Y, \mathcal{O}_Y)^C)^\vee$$

As these isomorphisms commute with the $H$-action we conclude that:

$$\text{Hom}_H(\pi_{1}^{ab}(Y), P) \simeq \text{Hom}_H(H^0(Y, \mathcal{O}_Y)^C, P)$$

So it suffices to compute:

$$\dim_{\mathbb{F}_p} \text{Hom}_H(H^0(Y, \mathcal{O}_Y)^C, P) = \dim_k \text{Hom}_H(H^0(Y, \mathcal{O}_Y)^C, k \otimes_{\mathbb{F}_p} P)$$
Because $k \otimes_{\mathfrak{g}_p} P$ is semi-simple, we need only to consider the largest semi-simple quotient of $H^0(Y, \Omega_Y)^{\gamma}$, that is $H^0(Y, \Omega_Y)^{\gamma}/\text{rad}(H^0(Y, \Omega_Y)^{\gamma})$. But using Definition 3.3, the isomorphisms $\Omega^2 k/\text{rad}\Omega^2 k \cong P(\Omega^2 k)/\text{rad} P(\Omega^2 k)$ and $P(\Omega^2 k) \cong \bigoplus_{V' \in S_H} P(V') \otimes \mathcal{H}(H, V')$ (see [3], Proposition 5), we finally see that:

$$H^0(Y, \Omega_Y)^{\gamma}/\text{rad}(H^0(Y, \Omega_Y)^{\gamma}) \cong \bigoplus_{V' \in S_H} V' \otimes \mathcal{H}(H, V') + \delta_{Y, V'}$$

hence:

$$\dim_k \text{Hom}_H(H^0(Y, \Omega_Y)^{\gamma}, k \otimes_{\mathfrak{g}_p} P) = \sum_{V' \in P} h^2(H, V') + \delta_{Y, V'} = \deg P(h^2(H, V') + \delta_{Y, V'})$$

\[\square\]

Lemma 3.8. Let $V \in S_H$. If the Kani inequalities hold, $G$ is a trivial extension of $H$ by $P$, and $V \mid P$, then $\delta_{Y, V} > 0$

Proof. Because of the Kani inequalities $\delta_{Y, V} \geq h^1(G, q^* V) - h^1(H, V)$, where $q$ is the epimorphism $q : G \to H$. We will show that $h^1(G, q^* V) - h^1(H, V) = 1$. In fact, using proposition 3.3, and the hypothesis that $G$ is the trivial extension, we get an exact sequence:

$$0 \to H^1(H, V) \to H^1(G, q^* V) \to H^1(P, V)^H \to 0$$

But now:

$$H^1(P, V)^H \simeq \text{Hom}_{\mathfrak{g}_p[H]}(P, V) \simeq \text{Hom}_{\mathfrak{g}_p[H]}(k \otimes_{\mathfrak{g}_p} P, V) \simeq k$$

\[\square\]

4. PROFINITE PROOF FOR THE EXTENSION OF A $p'$-GROUP BY A $p$-GROUP

In this section, we give another proof, almost purely algebraic, of the main Theorem 3.3 in the case of $H$ being a $p'$-group).

4.1. Finite quotients of a free pro-$p$-group with $p'$-action. Let $\gamma$ be a nonnegative integer and $F_\gamma$ be a free pro-$p$-group with $\gamma$ generators, endowed with a continuous action of a finite $p'$-group $H$.

Definition 4.1. For each $\mathcal{V} \in S_{\mathfrak{g}_p[H]}$ let $\delta_{\mathcal{V}}$ be the integer:

$$\delta_{\mathcal{V}} := \dim_{\mathfrak{g}_p} H^1(F_\gamma \rtimes H, \mathcal{V})$$

Remark:

In this definition, $\mathcal{V}$ is seen as a discrete $F_\gamma \rtimes H$-module via the canonical map $F_\gamma \rtimes H \to H$. Using the exact sequence $0 \to F_\gamma \to F_\gamma \rtimes H \to H \to 0$ we can also consider $\mathcal{V}$ as a trivial continuous $F_\gamma$-module, and the inflation-restriction sequence shows that $\delta_{\mathcal{V}} = \dim_{\mathfrak{g}_p} H^1(F_\gamma, \mathcal{V})^H = \dim_{\mathfrak{g}_p} \text{Hom}_H(F_\gamma, \mathcal{V})$. But any continuous morphism $F_\gamma \to \mathcal{V}$ is trivial on the (profinite) Frattini subgroup $\Phi(F_\gamma)$, hence $\delta_{\mathcal{V}} = \dim_{\mathfrak{g}_p} \text{Hom}_H(F_\gamma/\Phi(F_\gamma), \mathcal{V})$, which shows that the $\delta_{\mathcal{V}}$'s are actually finite.

Proposition 4.2. Let $P$ a finite $p$-group endowed with an action of $H$.

The following assertions are equivalent:

(i) There exists a continuous $H$-epimorphism $F_\gamma \to P$

(ii) $\forall \mathcal{V} \in S_{\mathfrak{g}_p[H]} \dim_{\mathfrak{g}_p} H^1(P \rtimes H, \mathcal{V}) \leq \delta_{\mathcal{V}}$. 

Proof. It is quite clear that (i) implies (ii) : a $H$-epimorphism $F_γ × H → P × H$, and the beginning of the corresponding inflation-restriction sequence for $V'$:

$$0 → H^1(P × H, V') → H^1(F_γ × H, V') → \cdots$$

allows to conclude that (ii) holds.

To see that (ii) implies (i) first notice that, as in the remark above, $\dim_p H^1(P × H, V') = \dim_p \text{Hom}_H(P/Φ(P), V')$. Moreover, since $H$ is a $p'$-group, the ring $F_p[H]$ is semi-simple, and for any $F_p[H]$-module of finite type, $\dim_p \text{Hom}_H(M, V')$ is exactly $\deg V'$ times the multiplicity of $V'$ in $M$. From this and (ii) we deduce the existence of a surjective $H$-map $F_γ/Φ(F_γ) → P/Φ(P)$, and so the existence of a group epimorphism $F_γ × H → P/Φ(P) × H$. Consider now the embedding problem :

$$\begin{array}{c}
F_γ × H \\
\downarrow \\
\downarrow \\
\downarrow \\
\downarrow \\
\downarrow \\
\downarrow \\
1 \rightarrow \Phi(P) \rightarrow P × H \rightarrow P/Φ(P) × H \rightarrow 1
\end{array}$$

According to [1], Chapitre I, §4.2, Proposition 24, Corollaire 2, et §3.3, Proposition 14, we certainly have $\text{cd}_p(F_γ × H) ≤ 1$. Hence (see 2.1.4) this embedding problem has a weak solution $F_γ × H → P × H$. This arrow commutes with projection on $H$, so we get a similar diagram without $H$'s, but for continuous $H$-morphisms. Now a classical argument (the Frattini subgroup $Φ(P)$ is precisely the set of non-generators in $P$) shows that the map $F_γ → P$ must be an epimorphism. \qed

Remark : One can of course ask if the $δ_{γ'}$'s do characterize the action of $H$ on $F_γ$. We have no answer.

4.2. Geometric application. Let now $Y → X$ be a Galois étalement cover of curves with Galois group $H$, a $p'$-group. By pushing the exact sequence $0 → π_1(Y) → π_1(X) → H → 0$ via the map $π_1(Y) → π_1^{(p)}(Y)$ we obtain a split exact sequence (because $\text{cd}_p H = 0$) which shows that $H$ acts naturally on $π_1^{(p)}(Y)$. Since this group is known to be pro-$p'$-free of rank $γ_Y$ (the classical Hasse–Witt invariant of $Y$), we can apply the result of the previous paragraph, with $γ = γ_Y$.

It is easy to see that Proposition 4.2 is equivalent to Theorem 1.1. The main point is that $F_γ/Φ(F_γ) ≃ H^0(Y, Ω_Y)^C$, which allows to see that if $V ∈ S_{k[H]}$, $V' ∈ S_{p[H]}$ are such that $V|\gamma V'$, then the $δ_{γ'}$’s of the previous paragraph coincide with our former $δ_{γ'}$’s.
