Capnocytophaga species are facultative anaerobic, capnophilic, fusiform, gram-negative bacilli exhibiting gliding motility; they are normal inhabitants of the oropharyngeal flora [1]. In addition, they are opportunistic pathogens associated with periodontal diseases and animal bites, causing systemic infection in both immunocompetent and immunocompromised hosts [2, 3]. To date, 9 species have been described in the genus Capnocytophaga, including C. canimorsus, C. cynodegmi, C. ochracea, C. gingivalis, C. sputigena, C. haemolytica, C. granulosa, C. leadbetteri, and genospecies AHN8471 [4]. Infections caused by Capnocytophaga species are infrequent, and species-level biochemical identification is difficult; thus, case reports of C. sputigena infection are rare [5-15]. We report a case of C. sputigena bacteremia in a patient with a hematologic malignancy.

A 40-yr-old man was admitted to our hospital for allogeneic bone marrow transplantation (BMT). After receiving a reduced-intensity conditioning regimen with fludarabine and busulfan, stem cells were infused into the patient. One hour later, his body temperature had risen to 39.2°C. After each 2 sets of blood cultures were taken from the peripheral veins and a central venous catheter, empirical antibiotic therapy with intravenous piperacillin-tazobactam was administered. Four years earlier, the patient had diagnosed as having symptomatic CLL. The following year, he received autologous peripheral blood stem cell transplantation and maintained remission, but CLL relapsed 6 months before admission.

Physical examination revealed no definitive focus of infection; the patient had a flat abdomen, clear breath sounds, and mild hyperemia of the oral mucosa. His blood pressure was 148/90 mmHg, pulse was 80/min, and respiratory rate was 20 breaths/min. Hematological tests showed the followings: Hb, 10.2 g/dL; leukocyte count, 0.05×10^9/L; platelet count, 37×10^9/L; C-reactive protein level, 6.41 mg/dL; blood urea nitrogen (BUN)/creatinine levels, 13/0.85 mg/dL; and total protein/albumin levels, 5.1/3.4 g/dL.

Two anaerobic blood cultures from the peripheral vein were positive after 3 days of incubation. The broths of positive cultures were inoculated onto blood agar plates (BAPs) and MacConkey agar plates (MACs), and incubated for 48 hr at 35°C in 5% CO2. Gray-colored non-hemolytic colonies grew on BAPs (Fig. 1A), whereas no colonies grew on MACs. Further biochemical tests showed that the isolates were C. sputigena, identified by positive reactions for catalase, oxidase, and Voges-Proskauer tests and negative reactions for indole and glucose fermentation. The isolate was also positive for hydrolysis of casein and sucrose and negative for hydrogen sulfide production.

lase-negative isolates and spindle-shaped gram-negative bacilli (Fig. 1B). By using matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF MS; Bruker Daltonik GmbH, Bremen, Germany) and Vitek2 HN system (bioMérieux, Marcy l’Etoile, France), the organism was identified as *C. sputigena* with a Bruker score of 2.039 and a 99% probability of being a *Capnocytophaga* species.

To confirm the identity of the isolate, we conducted 16S rRNA gene sequencing using the MicroSeq 500 system (Applied Biosystems, Foster City, CA, USA) with PCR and sequencing kits designed with universal primers to cover all bacteria. Sequences were analyzed by using an ABI PRISM 3730 Series DNA Analyzer (Applied Biosystems). The first 500 bp of the 16S rRNA gene sequence of the isolate showed 99.6% identity with the GenBank sequence AF133536 (*C. sputigena*) and 93.6% identity with NR_07450 (*C. ochracea*).

Antimicrobial susceptibility was tested by using the E-test (AB Biodisk, Solna, Sweden) on BAPs incubated for 48 hr at 35°C in 5% CO₂, and the results were interpreted by using Clinical and Laboratory Standards Institute breakpoints for HACEK group infections [16]. The isolate was susceptible to ampicillin, ampicillin-sulbactam, cefotaxime, ceftriaxone, chloramphenicol, clarithromycin, imipenem, meropenem, and tetracycline, but resistant to ciprofloxacin, levofloxacin, and trimethoprim-sulfamethoxazole.

Treatment with intravenous piperacillin-tazobactam was maintained, and follow-up blood cultures from the peripheral veins and a central venous catheter on days 3 and 10 were negative. The patient was successfully treated with a 12-day course of intravenous piperacillin-tazobactam, and the BMT was successful as determined by bone marrow examination 20 days after stem cell infusion.

Although *Capnocytophaga* species are oropharyngeal microbiota, they are rare opportunistic pathogens, especially in patients with hematologic malignancy after high-dose chemotherapy [1-3]. Among different species, *C. sputigena* has been involved in abscesses, bacteremia, chorioamnionitis, empyema, endocarditis, osteomyelitis, pleuropneumonia, sinusitis, and septic abortion [5-15]. Only 2 studies of *Capnocytophaga* infection, including bacteremia, periodontitis, and osteomyelitis, have been reported in Korea, but none of the cases identified the species of the causative organism [17]. To the best of our knowledge, this is the first report of *C. sputigena* bacteremia confirmed by 16S rRNA gene analysis in Korea.

Because conventional biochemical methods identify the genus level of *Capnocytophaga* species rather than the species level, the 16S rRNA gene analysis has been used for identification of *C. sputigena* [10-13]. By using MALDI-TOF MS, however, a fast and accurate identification of *C. sputigena* is now possible [14, 18]. There have been no reports on clinical differences based on distinct *Capnocytophaga* species and the necessity for species-level identification. If more laboratories use MALDI-TOF MS and publish reports on *Capnocytophaga* species, it is likely that this information will be forthcoming.

In the present case, since symptoms occurred immediately after the stem cell infusion, the stored stem cells may have been...
contaminated with the pathogen. However, C. sputigena is known to be present in normal oral flora, but there have been no reports showing their presence on the skin. Therefore, we assume that the oral cavity flora is the more likely source of infection, although the patient had no symptoms of oral mucositis.

Multidrug-resistant Capnocytophaga species, which present with a pattern of resistance to β-lactams and ciprofloxacin have been previously reported [19, 20]; however, the present isolate was susceptible to β-lactams but resistant to ciprofloxacin. Although there is no consensus guideline for the treatment of Capnocytophaga infections, the antibiotics to which Capnocytophaga species are already known to be susceptible, such as clindamycin, imipenem/cilastatin, and β-lactamase inhibitors, are appropriate choices for patient management [3].

In conclusion, we report the first Korean case of C. sputigena bacteremia confirmed by 16S rRNA gene analysis and MALDI-TOF MS. The present findings indicate that C. sputigena is an opportunistic pathogen in humans, especially in immunocompromised patients, such as those with hematologic malignancies.
