Enhancing Performance of Random Caching in Large-Scale Wireless Networks with Multiple Receive Antennas

Dongdong Jiang, Student Member, IEEE and Ying Cui, Member, IEEE

Abstract

To improve signal-to-interference ratio (SIR) and make better use of file diversity provided by random caching, we consider two types of linear receivers, i.e., maximal ratio combining (MRC) receiver and partial zero forcing (PZF) receiver, at users in a large-scale cache-enabled single-input multi-output (SIMO) network. First, for each receiver, by utilizing tools from stochastic geometry, we derive a tractable expression and a tight upper bound for the successful transmission probability (STP). In the case of the MRC receiver, we also derive a closed-form expression for the asymptotic outage probability in the low SIR threshold regime. Then, for each receiver, we maximize the STP. In the case of the MRC receiver, we consider the maximization of the tight upper bound on the STP by optimizing the caching distribution, which is a non-convex problem. We obtain a stationary point, by solving an equivalent difference of convex (DC) programming problem using concave-convex procedure (CCCP). We also obtain a closed-form asymptotically optimal solution in the low SIR threshold regime. In the case of the PZF receiver, we consider the maximization of the tight upper bound on the STP by optimizing the caching distribution and the degrees of freedom (DoF) allocation (for boosting the signal power), which is a mixed discrete-continuous problem. Based on structural properties, we obtain a low-complexity near optimal solution by using an alternating optimization approach. The analysis and optimization results reveal the impact of antenna resource at users on random caching. Finally, by numerical results, we show that the random caching design with the PZF receiver achieves significant performance gains over the random caching design with the MRC receiver and some baseline caching designs.

I. INTRODUCTION

The rapid proliferation of smart mobile devices has triggered an unprecedented growth of the global mobile data traffic. Motivated by the fact that a large portion of mobile data traffic is generated by many duplicate downloads of a few popular files, recently, caching popular files at the wireless edge, namely caching helpers (base stations and access points) has been proposed as a promising approach for reducing delay and backhaul load [1]–[3]. When the coverage regions of different helpers overlap, a user can fetch the desired file from multiple adjacent helpers, and hence the performance can be increased by caching different files among helpers, i.e., providing file diversity [4]. In [5]–[9], the authors consider caching in large-scale networks modeled using stochastic geometry. Specifically, in [5], the authors consider caching the most popular files at each helper, which does not provide file diversity. In [6], the authors consider random caching with uniform distribution at each helper. In [7], the authors consider random caching with files being stored at each helper in an i.i.d. manner according to the file popularity. In [8] and [9], the authors consider random joint caching and multicasting on the basis of file combinations consisting of different files, and analyze and optimize the joint design. Note that the random caching schemes in [6]–[9] can provide file diversity. However, in [6]–[9], a user may associate with a relatively farther helper when nearer helpers do not cache the requested file. In this case, the signal is usually weak compared with the interference, and the user may not successfully receive the requested file and benefit from file diversity offered by random caching.

To increase signal-to-interference ratio (SIR) under random caching, [10]–[13] study more sophisticated transmission schemes in large-scale networks. In particular, to increase receive signal power under random caching, [10]–[12] consider cooperative transmission schemes, where multiple nearest helpers [10], [11] or all helpers [12] storing the requested file of a user transmit it to the user, using non-coherent joint transmission [10], [12] and coherent joint transmission [11]. The successful transmission probability (STP) [10], [12] and the effective transmission rate [11] are analyzed and optimized. To reduce interference under random caching, in [13], the authors propose a periodic discontinuous transmission scheme, where each helper is on once every \( L \) slots and serves all file requests received during the latest \( L \) slots via multicast, reducing the interference to \( 1/L \) of that with all helpers being on. The STP is analyzed and optimized. Note that the cooperative transmission schemes in [10]–[12] are applicable mainly in lightly loaded networks, where multiple helpers can jointly serve a single user; the periodic discontinuous
transmission scheme in [13] increases the STP at the cost of delay increase.

Note that [10]–[13] focus on improving SIR for SISO transmission with single-antenna transmitters and receivers. Multi-antenna communication techniques provide another promising approach to increase SIR. In [14] and [15], the authors consider multi-input single-output (MISO) transmission, where each multi-antenna transmitter adopts a coordinated beamforming scheme to nullify inter-cell interference and increase receive signal power at single-antenna receivers, and analyze the coverage probability in large-scale wireless networks. In addition, in [16]–[18], the authors consider single-input multi-output (SIMO) transmission, where maximal ratio combining (MRC) receiver [16], partial zero-forcing (PZF) receiver [17] and minimum mean-square error (MMSE) receiver [18] are adopted at each multi-antenna receiver to increase the receive signal power or suppress the interference, and analyze the scaling law of the spectrum efficiency [16], the scaling law of the transmission capacity [17] and the outage probability [18] in large-scale wireless networks. Note that [14]–[18] do not consider caching. Recently, [19] and [20] focus on improving SIR under random caching in large-scale MISO networks. Specifically, in [19], the authors consider maximal ratio transmission (MRT) beamforming to improve receive signal power, and analyze and optimize the area spectrum efficiency. In [20], the authors consider zero-forcing beamforming (ZFBF) to simultaneously serve multiple single-antenna users without causing intra-cell interference, and analyze and optimize the STP and the area spectral efficiency. Note that the MRT beamforming scheme in [19] and the ZFBF scheme in [20] require perfect CSI at transmitters. In addition, [19] does not consider interference management, and [20] studies interference management which may not be very efficient from the user’s point of view. Finally, in [19], the performance expression involves inverse of matrices, which is difficult to evaluate and provides little insight, and the adopted gradient projection method for solving the non-convex caching optimization problem has high computation complexity and possibly slow convergence; in [20], the authors analyze and optimize the STP and the area spectrum efficiency under several approximations.

Note that [19] and [20] focus on revealing the impact of antenna resource at transmitters on improving SIR under random caching. It is not known whether antenna resource at receivers can achieve a similar or even more important role in SIR improvement under random caching. In this paper, we would like to investigate how multiple receive antennas at users can help improve SIR for content delivery when single-antenna helpers employ random caching in a large-scale cache-enabled SIMO network. Specifically, we consider $M$-antenna users and study two types
of linear receivers for two cases of CSI at users. First, we consider the direct CSI case where each user has knowledge of the CSI of the direct link between its serving helper and itself, and perform MRC at each user to increase the receive signal power. Next, we consider the local CSI case where each user has knowledge of the CSI of the links between its nearby (at most $M - 1$ nearest) interfering helpers and itself as well as the direct link, and perform PZF at each user to simultaneously increase the receive signal power and suppress the interference. Note that the two receive schemes only require CSI at receivers and do not require CSI at transmitters. In addition, the PZF receiver can suppress interference from nearby interferers more efficiently from the user’s point of view. Our main contributions are summarized below.

- First, we analyze the STP. In the case of the MRC receiver, by utilizing tools from stochastic geometry and inequalities for the incomplete gamma function, we derive a tractable expression and closed-form upper and lower bounds for the STP. The two bounds are tight when $M = 1$, and the upper bound is shown to be a good approximation for the STP at all $M$. We also derive a closed-form expression for the asymptotic outage probability in the low SIR threshold regime, utilizing series expansion of some special functions. In the case of the PZF receiver, by utilizing tools from stochastic geometry and relative locations of the serving helper and interferers, we derive a tractable expression and a simpler upper bound for the STP. The upper bound is shown to be a good approximation for the STP at all $M$. The analysis results reveal that the STPs with the MRC and PZF receivers both increase with $M$.

- Next, we maximize the STP. In the case of the MRC receiver, we consider the maximization of the simpler upper bound on the STP by optimizing the caching distribution, which is a non-convex problem. By exploring structural properties of the problem, we successfully transform the original non-convex problem into a difference of convex (DC) programming problem, and obtain a stationary point of the original problem, using concave-convex procedure (CCCP). We also obtain a closed-form asymptotically optimal solution in the low SIR threshold regime. In the case of the PZF receiver, we consider the maximization of the simpler upper bound on the STP by optimizing the caching distribution and the degrees of freedom (DoF) allocation, which is a mixed discrete-continuous problem. By exploring structural properties of the problem, we obtain a low complexity near optimal solution by an alternating optimization approach. The optimization results indicate that files of higher
popularity get more storage resources, and the optimized caching distributions for the MRC and PZF receivers both become more flat when $M$ is larger.

- Finally, we show that the proposed random caching design with the PZF receiver achieves significant performance gains over the proposed random caching design with the MRC receiver and some baseline caching schemes, using numerical results.

II. SYSTEM MODEL AND PERFORMANCE METRIC

A. Network Model

We consider a large-scale cache-enabled network as shown in Fig. 1. The locations of caching helpers are spatially distributed as a two-dimensional homogeneous Poisson point process (PPP) $\Phi_h$ with density $\lambda_h$. The locations of users are distributed as an independent two-dimensional homogeneous PPP with density $\lambda_u$. According to Slivnyak’s theorem [21], we focus on a typical user $u_0$, which we assume without loss of generality (w.l.o.g.) to be located at the origin. The helpers are labeled in ascending order of distance from $u_0$. Let $d_i$ denote the distance between helper $i \in \Phi_h$ and $u_0$. Thus, we have $d_1 \leq d_2 \leq \cdots$. We consider the downlink transmission. Each helper has one transmit antenna with transmission power $P$. All helpers transmit over the same frequency band. Each user has $M$ receive antennas. That is, we focus on SIMO transmission. Due to path loss, transmitted signals with distance $d$ are attenuated by a factor $d^{-\alpha}$, where $\alpha > 2$ is the path loss exponent. Let $h_{i,0} \in \mathbb{C}^{M \times 1}$ denote the small-scale fading vector between helper $i \in \Phi_h$ and $u_0$. We assume that all entries of $h_{i,0}$ are i.i.d. complex Gaussian random variables, each with zero mean and unit variance, i.e., $\mathcal{CN}(0,1)$.

Let $\mathcal{N} \triangleq \{1, 2, \cdots, N\}$ denote the set of $N$ files in the network. For ease of illustration, we assume that all files have the same size. The popularity distribution among $\mathcal{N}$ is assumed to be known apriori and is denoted by $\mathbf{a} \triangleq (a_n)_{n \in \mathcal{N}}$. That is, $u_0$ randomly requests one file, which is file $n \in \mathcal{N}$ with probability $a_n$, where $\sum_{n \in \mathcal{N}} a_n = 1$. In addition, w.l.o.g., we assume $a_1 > a_2 \ldots > a_N$.

\footnote{The system model is similar to the one we considered in [8], except that here we consider multi-antenna users. Here, we briefly illustrate the system model for completeness.}

\footnote{Note that the analysis and optimization results in this paper can be extended to MIMO transmission with open-loop spatial multiplexing, by treating one multi-antenna helper sending multiple data streams as multiple co-located virtual single-antenna helpers, each sending one data stream, as illustrated in [22].}
Fig. 1. System model ($N = 3$, $C = 2$). There are three files in the network, represented by the red, yellow and blue colors, respectively. Each circle represents a user, the color of which indicates the file requested by the user. Each square represents a caching helper, the color of which indicates the two different files stored at the helper [8].

B. Random Caching Design

The network consists of cache-enabled helpers. In particular, each helper is equipped with a cache of size $C \geq 1$ (in files) and can serve any files stored locally. Assume each helper cannot store all files in $\mathcal{N}$ due to the limited storage capacity, i.e., $C < N$. To provide spatial file diversity (which can improve performance of dense wireless networks), we adopt a random caching design at helpers [8]. In particular, each helper stores $C$ different files out of all $N$ files in $\mathcal{N}$ with a certain probability. Let $T_n$ denote the probability of file $n$ being stored at each helper. Then, we have

$$1 \leq T_n \leq 1, \quad n \in \mathcal{N},$$

$$\sum_{n \in \mathcal{N}} T_n = C.$$  

Denote $\mathbf{T} \triangleq (T_n)_{n \in \mathcal{N}}$, which is termed as the caching distribution. In this paper, we focus on serving cached files to get first-order insights into the design of cache-enabled SIMO wireless networks.

Each user requesting a file is associated with the nearest helper storing this file, referred to as its serving helper, as this helper offers the maximum long-term average receive power for this file. Suppose $u_0$ requests file $n$. Let $\ell_{0,n} \in \Phi_h$ denote the index of the serving helper of $u_0$. Note that the serving helper of $u_0$ may not be its geographically nearest helper, and the distance between $u_0$ and its serving helper is statistically determined by $T_n$. This association mechanism is referred to as the content-centric association [8]. Different from the traditional connection-based association [22], this association jointly considers the physical layer and content-centric properties.
C. Receive Filters

For analytical tractability, as in [4], [5] and [22], we assume that all helpers are active for serving their own users (e.g., in the case of $\lambda_u \gg \lambda_h$). Suppose $u_0$ requests file $n$. Then, the received signal of $u_0$, denoted as $y_n \in \mathbb{C}^{M \times 1}$, is given by

$$y_n = d_{\ell_0,n}^{-\frac{\alpha}{2}} h_{\ell_0,n,0} s_{\ell_0,n} + \sum_{i \in \Phi_h \setminus \{\ell_0,n\}} d_i^{-\frac{\alpha}{2}} h_{i,0} s_i + z_0,$$

where $s_i$ is the transmit signal of helper $i$ with $\mathbb{E}[\|s_i\|^2] = P$ and $z_0 \in \mathbb{C}^{M \times 1}$ is complex Gaussian noise vector at $u_0$. As in [4], in the following, we consider an interference-limited case (i.e., the noise power is negligible compared to the interference power) and ignore the noise.

Denote $w_0 \in \mathbb{C}^{M \times 1}$ as the receive filter adopted by $u_0$ for receiving the signal of its serving helper. That is, $u_0$ detects signal $s_{\ell_0,n}$ based on $w_{0,n}^H y_n$, where $w_{0,n}^H$ denotes the conjugate transpose of vector $w_{0,n}$. The performance of the cache-enabled SIMO network depends on the choices of the receive filter. In the following, we consider two types of linear receivers for two different CSI cases, respectively.

First, we consider the case where each user has only knowledge of the CSI of its direct link, i.e., the link between its serving helper and itself, referred to as direct CSI. Obtaining direct CSI can be done using a control channel with a reasonable amount of pilot signal overhead [16]. Given direct CSI only, we consider the MRC receiver, which is the optimal receiving strategy to maximize the signal power in SIMO transmission. In particular, the MRC receive filter is given by $w_{0,n}^{\text{mrc}} = \frac{h_{\ell_0,n,0}}{\|h_{\ell_0,n,0}\|_2}$, and the corresponding SIR of $u_0$ is given by

$$\text{SIR}_{\text{mrc}} = \frac{H_{\ell_0,n,0}^\text{mrc} d_{\ell_0,n}^{-\alpha}}{\sum_{i \in \Phi_h \setminus \{\ell_0,n\}} H_{i,0}^\text{mrc} d_i^{-\alpha}},$$

(3)

where $H_{\ell_0,n,0}^\text{mrc} \triangleq \| (w_{0,n}^{\text{mrc}})^H h_{\ell_0,n,0} \|_2^2 = \| h_{\ell_0,n,0} \|_2^2$ denotes the fading power of the direct link, and $H_{i,0}^\text{mrc} \triangleq \| (w_{0,n}^{\text{mrc}})^H h_{i,0} \|_2^2$ denotes the fading power of the link between helper $i \in \Phi_h \setminus \{\ell_0,n\}$ and $u_0$. Here, $H_{\ell_0,n,0}^- \sim \text{Gamma}(M, 1)$ and $H_{i,0}^- \sim \text{Exp}(1)$ [17]. Note that MISO transmission with the MRT beamformer can achieve a SIR of the same distribution as the one in (3), based on CSI at transmitters [19].

Next, we consider the case where each user is able to learn the CSI of the links between its nearby (at most $M - 1$ nearest) interfering helpers and itself as well as the direct link, referred to as local CSI. Given local CSI, we adopt a PZF receiver, which uses a subset of the $M$ DoF for boosting signal power and the remainder for interference cancellation. In particular, at $u_0$, $K_n$ DoF is allocated to boost the signal power for file $n$ and $M - K_n$ DoF is used to cancel the interferences from the $M - K_n$ nearest interfering helpers, where $K_n$ satisfies

$$K_n \in \mathcal{M} \triangleq \{1, 2, \cdots, M\}, \quad n \in \mathcal{N}.$$
Thus, the adopted PZF receiver depends on parameter $K \triangleq (K_n)_{n \in \mathcal{N}}$. Let $c_i$ denote the index of the $i$-th nearest interfering helper. The PZF receive filter $w_{0,n}^{\text{pzf}}$ is the projection of the channel vector $h_{\ell_0,n,0}$ onto the subspace orthogonal to the one spanned by the channel vectors $h_{c_1,0}, h_{c_2,0}, \ldots, h_{c_{M-K_n},0}$ of the $M-K_n$ canceled interferers $c_1, c_2, \ldots, c_{M-K_n}$. If the columns of an $M \times K_n$ matrix $\mathbf{U}_0$ form an orthonormal bases of the subspace, then the PZF receive filter is given by $w_{0,n}^{\text{pzf}} = \frac{\mathbf{u}_{0,n}^H h_{\ell_0,n,0}}{\|\mathbf{u}_{0,n}^H h_{\ell_0,n,0}\|^2}$. By applying this filter, the interferences from the $M-K_n$ nearest interfering helpers $c_1, c_2, \ldots, c_{M-K_n}$ are suppressed and the corresponding SIR of $u_0$ is given by

$$\text{SIR}^{\text{pzf}}_n = \frac{H_{\ell_0,n,0}^{\text{pzf}} d_{\ell_0,n}^{-\alpha}}{\sum_{i \in \Phi_n \setminus \{\ell_0,n,c_1,c_2,\ldots,c_{M-K_n}\}} H_{i,0}^{\text{pzf}} d_{i}^{-\alpha}},$$

where $H_{\ell_0,n,0}^{\text{pzf}} \triangleq \| (w_{0,n}^{\text{pzf}})^H h_{\ell_0,n,0} \|^2_2$ denotes the fading power of the direct link and $H_{i,0}^{\text{pzf}} \triangleq \| (w_{0,n}^{\text{pzf}})^H h_{i,0} \|^2_2$ denotes the fading power of the link between the caching helper $i$ and $u_0$. Here, $H_{\ell_0,n,0}^{\text{pzf}} \sim \text{Gamma}(K_n, 1)$ and $H_{i,0}^{\text{pzf}} \sim \text{Exp}(1)$ [17]. The PZF receiver is more general than the MRC receiver and reduces to the MRC receiver when $K_n = M$. Note that the PZF receiver can efficiently cancel interference from the user’s point of view, as a user is aware of its nearby interferers. Note that MISO transmission with a similar PZF beamformer may not achieve a SIR of the same distribution as the one in (5), even with CSI at transmitters and information on nearby interferers of users (obtained via feedback from users).

### D. Performance Metric

When using the MRC receiver in the case of direct CSI, the transmission of file $n$ to $u_0$ is successful if $\text{SIR}^{\text{mrc}}_n \geq \tau$, where $\tau$ is the SIR threshold. When using the PZF receiver in the case of local CSI, the transmission of file $n$ to $u_0$ is successful if $\text{SIR}^{\text{pzf}}_n \geq \tau$. Therefore, the STPs of file $n \in \mathcal{N}$ requested by $u_0$ with the MRC receiver and the PZF receiver, denoted as $q^{\text{mrc}}_{M,n}(T_n)$ and $q^{\text{pzf}}_{M,n}(K_n, T_n)$ respectively, are given by

$$q^{\text{mrc}}_{M,n}(T_n) \triangleq \Pr[\text{SIR}^{\text{mrc}}_n \geq \tau],$$

$$q^{\text{pzf}}_{M,n}(K_n, T_n) \triangleq \Pr[\text{SIR}^{\text{pzf}}_n \geq \tau],$$

where $\text{SIR}^{\text{mrc}}_n$ and $\text{SIR}^{\text{pzf}}_n$ are given by (3) and (5), respectively. Note that the distributions of $\text{SIR}^{\text{mrc}}_n$ and $\text{SIR}^{\text{pzf}}_n$ depend on $T_n$ and $(T_n, K_n)$, respectively. Thus, we write $q^{\text{mrc}}_{M,n}$ and $q^{\text{pzf}}_{M,n}$ as functions of $T_n$ and $(T_n, K_n)$, respectively. Requesters are mostly concerned about whether their desired files can be successfully received. Therefore, as in [8], we consider the STP of a file randomly requested by $u_0$ as the network performance metric. According to the total

\footnote{Note that [19] considers random caching and MRT in MISO transmission for a large-scale cache-enabled network and studies a different performance metric. Therefore, the analysis and optimization framework in this paper is different from that in [19].}
probability theorem, the STPs of a file randomly requested by \( u_0 \) with the MRC receiver and the PZF receiver, denoted as \( q_{M,\text{MRC}}(T) \) and \( q_{M,\text{PZF}}(K, T) \) respectively, are given by

\[
q_{M,\text{MRC}}(T) \triangleq \Pr[\text{SIR}_{\text{MRC}} \geq \tau] = \sum_{n \in \mathcal{N}} a_n q_{M,n,\text{MRC}}(T_n), \tag{6}
\]

\[
q_{M,\text{PZF}}(K, T) \triangleq \Pr[\text{SIR}_{\text{PZF}} \geq \tau] = \sum_{n \in \mathcal{N}} a_n q_{M,n,\text{PZF}}(K_n, T_n). \tag{7}
\]

### III. Performance Analysis and Optimization for MRC Receiver

In this section, we consider the performance analysis and optimization of the random caching design with the MRC receiver in the case of direct CSI. First, we analyze the STP in the general SIR threshold regime and the low SIR threshold regime, respectively. Then, we optimize the STP in these regimes.

#### A. Performance analysis for MRC Receiver

1) **Performance Analysis in General SIR Threshold Regime:** Note that different from [22], in the cache-enabled wireless network considered, there are two types of interferers, namely, i) interfering helpers storing the file requested by \( u_0 \) (which are farther than the serving helper of \( u_0 \)), and ii) interfering helpers without the desired file of \( u_0 \) (which can be closer to \( u_0 \) than the serving helper of \( u_0 \)). Different from [8], \( u_0 \) has \( M \) receive antennas and performs MRC to detect its desired signal. By carefully handling these two types of interferers and characterizing the impact of MRC, we obtain \( q_{M,n,\text{MRC}}(T_n) \) using stochastic geometry. Substituting \( q_{M,n,\text{MRC}}(T_n) \) into (6), we have the following result.

**Theorem 1 (STP with MRC Receiver in General SIR Threshold Regime):** The STP with the MRC receiver is given by

\[
q_{M,\text{MRC}}(T) = \sum_{n \in \mathcal{N}} a_n q_{M,n,\text{MRC}}(T_n),
\]

where

\[
q_{M,n,\text{MRC}}(T_n) = 2\pi \lambda h T_n \int_0^{\infty} x \exp\left(-\pi \lambda h T_n x^2\right) \sum_{m=0}^{M-1} \frac{1}{m!} \sum_{k=0}^{m} \binom{m}{k} \tilde{L}_I(T_n, x, x) \tilde{L}_I^{m-k}(1 - T_n, x, 0) dx,
\]

\[
\tilde{L}_I(T, x, y) = \exp\left(-\frac{2\pi \lambda h T \tau^2}{\alpha} \frac{x^2}{B'(\frac{2}{\alpha} + 1 + \frac{1}{1 + \tau(y)} \alpha)}\right),
\]

\[
\tilde{L}_I^k(T, x, y) = \tilde{L}_I(T, x, y) \sum_{(b_j)_{j=1}^k \in \mathcal{M}_k} \frac{k!}{\prod_{j=1}^k b_j!} \prod_{j=1}^k \left(\frac{2\pi \lambda T \tau^2}{\alpha} \frac{x^2}{B'\left(\frac{2}{\alpha} + 1, j - \frac{2}{\alpha} + \frac{1}{1 + \tau(y)} \alpha\right)}\right)^{b_j}.
\]

Here, \( \mathcal{M}_k \triangleq \{(m_j)_{j=1}^k | m_j \in \mathbb{N}_0^0, \sum_{j=1}^k j \cdot m_j = k\} \), \( \mathbb{N}_0^0 \) denotes the set of nonnegative integers and \( B'(a, b, z) \triangleq \int_1^z u^{a-1}(1 - u)^{b-1} du \) (0 < \( z < 1 \)) denotes the complementary incomplete beta function.

**Proof:** Please refer to Appendix A.
From Theorem 1 we can see that the STP $q_{M}^{\text{mrc}}(T)$ is an increasing function of the number of receive antennas $M$ at each user. In particular, when increasing the number of receive antennas from $M - 1$ to $M$, the increase of the STP of file $n$ is

$$q_{M,n}^{\text{mrc}}(T_n) - q_{M-1,n}^{\text{mrc}}(T_n) = \frac{2\pi h T_n}{(M-1)!} \int_{0}^{\infty} x \exp \left(-\pi h T_n x^2\right) \sum_{k=0}^{M-1} \frac{(M-1)_k}{k} \beta^k(T_n, x) \Lambda^{M-1-k}(1-T_n, x, 0) dx > 0. \tag{11}$$

From Theorem 1 we also see that the impact of the physical layer parameters $\alpha$, $\tau$, $\lambda_h$ and the impact of the caching distribution $T$ on $q_{M}^{\text{mrc}}(T)$ are coupled in a very complex manner. Fig. 2 plots $q_{M}^{\text{mrc}}(T)$ versus $\tau$ at different $M$. From Fig. 2 we can see that each “analytical” curve (plotted using Theorem 1) closely matches the corresponding “Monte Carlo” curve, verifying Theorem 1. In addition, from Fig. 2 we can see that $q_{M}^{\text{mrc}}(T)$ increases with $M$.

When $M = 1$, by Theorem 1 we can obtain a simplified closed-form expression for $q_{1}^{\text{mrc}}(T)$.

**Corollary 1 (STP with MRC Receiver for $M = 1$):** For $M = 1$, the STP with the MRC receiver is $q_{1}^{\text{mrc}}(T) = \sum_{n \in M} a_n q_{1,n}^{\text{mrc}}(T_n)$, where

$$q_{1,n}^{\text{mrc}}(T_n) = \frac{T_n}{c_{1,1}(1)T_n + c_{2,1}(1)}.$$ 

Here, $c_{1,k}(x)$ and $c_{2,k}(x)$ are given by

$$c_{1,k}(x) \triangleq \frac{2}{\alpha} (k \tau)^{\frac{k}{2}} B\left(\frac{2}{\alpha}, 1 - \frac{2}{\alpha}, \frac{1}{1 + k \tau}\right) - B\left(\frac{2}{\alpha}, 1 - \frac{2}{\alpha}, 1\right) + 1, \tag{12}$$

$$c_{2,k}(x) \triangleq \frac{2}{\alpha} (k \tau)^{\frac{k}{2}} B\left(\frac{2}{\alpha}, 1 - \frac{2}{\alpha}, 1\right), \tag{13}$$

where $B(a, b) \triangleq \int_{0}^{1} u^{a-1}(1-u)^{b-1} du$ denotes the beta function.

Note that Corollary 1 coincides with Corollary 4 of our previous work [8], which considers single-antenna users. From Corollary 1 we can see that the impact of the physical layer parameters $\alpha$ and $\tau$ (captured by $c_{1,1}(1)$ and $c_{2,1}(1)$) and the impact of the caching distribution $T$ on the STP $q_{1}^{\text{mrc}}(T)$ can be easily separated. In addition, $q_{1,n}^{\text{mrc}}(T_n)$ is a concave increasing function of $T_n$. This is because the average distance between a user requesting file $n$ and its serving helper decreases with $T_n$.

To facilitate the characterization of the STP $q_{M}^{\text{mrc}}(T)$ for $M \geq 2$, we next derive its closed-form upper and lower bounds, based on the upper and lower bounds on the incomplete gamma function, i.e., $(1 - e^{-S_a b})^{a} < \gamma(a, b) < (1 - e^{-b})^{a}$ for $a > 1$, where $S_a \triangleq \Gamma(a + 1) - a$. [23]

**Lemma 1 (Upper and Lower Bounds):** The upper bound is given by $q_{M,n}^{\text{mrc}, u}(T) = \sum_{n \in M} a_n q_{M,n}^{\text{mrc}, u}(T_n)$, where

$$q_{M,n}^{\text{mrc}, u}(T_n) \triangleq 1 - \sum_{k=0}^{M} \binom{M}{k} \frac{(-1)^k T_n}{c_{1,k}(S_M) T_n + c_{2,k}(S_M)},$$

January 10, 2018 DRAFT
and the lower bound is given by $q_{M,n}^{\text{mrc},l}(T_n) = \sum_{n\in\mathcal{N}} a_n q_{M,n}^{\text{mrc},l}(T_n)$, where

$$q_{M,n}^{\text{mrc},l}(T_n) \triangleq 1 - \sum_{k=0}^{M} \binom{M}{k} \frac{(-1)^k T_n}{c_{1,k}(1) T_n + c_{2,k}(1)}.$$  

Here, $c_{1,k}(x)$ and $c_{2,k}(x)$ are given by (12) and (13), respectively.

**Proof:** Please refer to Appendix B.

Note that the upper bound $q_{M}^{\text{mrc},u}(T)$ and the lower bound $q_{M}^{\text{mrc},l}(T)$ coincide when $M = 1$, i.e., $q_{M}^{\text{mrc},u}(T) = q_{M}^{\text{mrc},l}(T) = q_{M}^{\text{mrc}}(T)$, implying that the two bounds are tight at $M = 1$. Similarly, for $M \geq 2$, the impact of the physical layer parameters $\alpha$ and $\tau$ (captured by $c_{1,k}(k)$, $c_{2,k}(k)$, $k \in \{0, \cdots, M\}$) and the impact of the caching distribution $T$ on $q_{M}^{\text{mrc},u}(T)$ and $q_{M}^{\text{mrc},l}(T)$ can be easily separated.

Fig. 2 plots $q_{M}^{\text{mrc},u}(T)$, $q_{M}^{\text{mrc},l}(T)$ and $q_{M}^{\text{mrc}}(T)$ versus $\tau$ at different $M$. From Fig. 2 we can see that when $M = 1$, $q_{M}^{\text{mrc}}(T)$, $q_{M}^{\text{mrc},u}(T)$ and $q_{M}^{\text{mrc},l}(T)$ coincide; when $M \geq 2$, $q_{M}^{\text{mrc},u}(T)$ and $q_{M}^{\text{mrc},l}(T)$ bound $q_{M}^{\text{mrc}}(T)$ from above and below, respectively. In addition, $q_{M}^{\text{mrc},u}(T)$ tightly matches $q_{M}^{\text{mrc}}(T)$ over the entire range of SIR threshold $\tau$ of interest, demonstrating that $q_{M}^{\text{mrc},u}(T)$ can serve as a good approximation for $q_{M}^{\text{mrc}}(T)$.

2) **Performance Analysis in Low SIR Threshold Regime:** Although the impacts of the physical layer parameters and the caching distribution can be separated in $q_{M}^{\text{mrc},u}(T)$, how these parameters affect $q_{M}^{\text{mrc},u}(T)$ is still not clear. To further obtain insights, we analyze the outage probability $q_{M}^{\text{mrc}}(T) \triangleq \Pr [\text{SIR}^{\text{mrc}} < \tau] = 1 - q_{M}^{\text{mrc}}(T)$ in the low SIR threshold regime, i.e., $\tau \to 0$.

\(^4\)The downlink transmission in the LTE system supports an SINR about $−7$ dB. Thus, $\tau$ can be very small and the asymptotic analysis is applicable in certain scenarios \(24\).
Fig. 3. Outage probability with the MRC receiver versus SIR threshold $\tau$. $N = 5, C = 3, \alpha = 4, \lambda = 10^{-3}$, $T = [1, 0.8, 0.6, 0.4, 0.2]$, and $a_n = \frac{n^{-\gamma}}{\sum_{n \in \mathcal{N}} n^{-\gamma}}$ with $\gamma = 1$.

**Lemma 2 (Outage Probability with MRC Receiver in Low SIR Threshold Regime):** As $\tau \to 0$, $\bar{q}_{M}^{\text{mrc}}(T) = \bar{q}_{M,0}^{\text{mrc}}(T) + o(\tau^{2/\alpha})$, where

$$
\bar{q}_{M,0}^{\text{mrc}}(T) = \sum_{n \in \mathcal{N}} a_n \bar{q}_{M,0,n}^{\text{mrc}}(T_n),
$$

(14)

$$
\bar{q}_{M,0,n}^{\text{mrc}}(T_n) = \tau^2 \frac{2}{\alpha} \left( \frac{1}{T_n - 1} \right) \sum_{m=M}^{\infty} \frac{B \left( \frac{2}{\alpha} + 1, m - \frac{2}{\alpha} \right)}{m}.
$$

(15)

**Proof:** Please refer to Appendix C.

First, we introduce the order gain of the outage probability, defined as the exponent of the outage probability as SIR threshold $\tau$ decreases to 0 [24], i.e., $d_{\text{mrc}} \triangleq \lim_{\tau \to 0} \frac{\log \Pr\{\text{SIR}_{\text{mrc}} < \tau\}}{\log \tau}$. Then, we define the coefficient of the asymptotic outage probability, i.e., $e_{\text{mrc}} \triangleq \lim_{\tau \to 0} \frac{\Pr\{\text{SIR}_{\text{mrc}} < \tau\}}{\tau d_{\text{mrc}}}$.

Leveraging its order gain and the coefficient, we now characterize the key behavior of the outage probability $\bar{q}_{M}^{\text{mrc}}(T)$ in the low SIR threshold regime based on Lemma 2. Specifically, the order gain $d_{\text{mrc}}$ is $\frac{2}{\alpha}$, which does not depend on the number of receive antennas $M$ and the caching distribution $T$. The coefficient $e_{\text{mrc}}$ is affected by $M$ and $T$. Specifically, when increasing the number of receive antennas from $M - 1$ to $M$, the decrease of the coefficient $e_{\text{mrc}}$ is $\frac{2}{\alpha}$, which does not depend on the number of receive antennas $M$ and the caching distribution $T$.

Fig. 3 plots $\bar{q}_{M}^{\text{mrc}}(T)$ and $\bar{q}_{M,0}^{\text{mrc}}(T)$ versus the SIR threshold $\tau$ in the low SIR threshold regime. We can see from Fig. 3 that when $\tau$ decreases, the gap between each “General” curve $\bar{q}_{M}^{\text{mrc}}(T)$, which is plotted using Theorem 1 and the corresponding “Asymptotic” curve $\bar{q}_{M,0}^{\text{mrc}}(T)$, which is plotted using Lemma 2 decreases, verifying Lemma 2. In addition, from Fig. 3, we can see that “Asymptotic” curves with different $M$ have the same slope (implying the same order gain), and there is a shift between two “Asymptotic” curves with different $M$ (implying different coefficients).
B. Performance Optimization for MRC Receiver

1) Performance Optimization in General SIR Threshold Regime: In the general SIR threshold regime, we would like to optimize $T$ to maximize the STP with the MRC receiver. Recall that the closed-form upper bound $q_{mrc,u M}^{M}(T)$ provides a good approximation for $q_{mrc}^{M}(T)$, as shown in Fig. 2. In addition, $q_{mrc,u M}^{M}(T)$ has a much simpler form than $q_{mrc}^{M}(T)$. Thus, in the following, we maximize $q_{mrc,u M}^{M}(T)$ instead of directly maximizing $q_{mrc}^{M}(T)$.

Problem 1 (Performance Optimization for MRC Receiver):

$$
\max_T \ q_{mrc,u M}^{M}(T) \\
s.t. \qquad (1), \ (2).
$$

When $M = 1$, Problem 1 is a convex optimization problem, and its closed-form optimal solution is given in Theorem 4 of our previous work [8]. When $M \geq 2$, Problem 1 is in general a non-convex optimization problem with a differentiable non-convex objective function and a convex constraint set. The gradient projection method can be applied to obtain a stationary point of Problem 1. However, the rate of convergence of the gradient projection algorithm is strongly dependent on the choices of the stepsize and initial point. If they are chosen improperly, it may take a large number of iterations to meet some convergence criterion [25]. To address this issue, in the following, we propose a more efficient algorithm to obtain a stationary point of Problem 1.

First, we can see that Problem 1 is equivalent to the minimization of the difference of two convex functions $R_o(T) \triangleq - \sum_{n \in N} a_n \sum_{i=0}^{\left\lfloor M/2 \right\rfloor} (M) \frac{T_n}{C_{1,2i+1}(S_M)T_n+C_{2,2i+1}(S_M)}$ and $R_e(T) \triangleq - \sum_{n \in N} a_n \sum_{i=0}^{\left\lfloor M/2 \right\rfloor} (M) \frac{T_n}{C_{1,2i+1}(S_M)T_n+C_{2,2i+1}(S_M)}$ subject to the constraints in (1) and (2), which is given below.

Problem 2 (Equivalent Problem of Problem 1):

$$
\min_T \ R_o(T) - R_e(T) \\
s.t. \qquad (1), \ (2).
$$

Problem 2 is a DC programming problem [26]. Note that constructing an algorithm to find a globally optimal solution of a DC programming problem is in general an open problem. We use

---

5 Note that a stationary point is a point that satisfies the necessary optimality conditions of a non-convex optimization problem, and it is the classic goal in the design of iterative algorithms for non-convex optimization problems.

6 An optimization problem is called a DC programming problem if its variables are restricted to a convex set and its objective function and its inequality constraint functions are DC functions [26].
Algorithm 1 does not rely on any stepsize. From [27], we know that Algorithm 1 converges using CCCP are summarized in Algorithm 1. Different from the gradient projection method, we can efficiently obtain a stationary point of Problem 2 based on CCCP (i.e., \( R_e(T) \)) with its first order Taylor expansion, and then solve a sequence of convex problems successively. Specifically, at iteration \( t \) of CCCP, we have the following problem.

**Problem 3 (Problem at Iteration \( t \) of CCCP):**

\[
\min_T R_o(T) + \sum_{n \in \mathcal{N}} a_n f_e(T_n^t(t - 1)T_n
\]

subject to (1), (2),

where \( f_e(x) \triangleq -\frac{1}{a_n} \frac{\partial R_o(T)}{\partial T_n} \bigg|_{T_n=x} = \sum_{i=0}^{M-1} \frac{i}{2i+1} \frac{C_{2i+1}(S_M)}{(C_{1,2i+1}(S_M)x+C_{2,2i+1}(S_M))^2} \), and \( T_n^t(t) \) denotes the optimal solution of the problem at iteration \( t \) of CCCP.

It can be easily seen that Problem 3 is a convex optimization problem and Slater’s condition is satisfied, implying that strong duality holds. Using KKT conditions, we can solve Problem 3.

**Lemma 3 (Optimal Solution of Problem 3):** The optimal solution \( T_n^t(t) \) of Problem 3 is

\[
T_n^t(t) = \begin{cases} 
0, & f_o(0) < f_e(T_n^t(t - 1)) + \frac{v^t(t)}{a_n}, \\
1, & f_o(1) > f_e(T_n^t(t - 1)) + \frac{v^t(t)}{a_n}, \\
x(T_n^t(t - 1), a_n, v(t)), & \text{otherwise}
\end{cases},
\]

where \( f_o(x) \triangleq -\frac{1}{a_n} \frac{\partial R_o(T)}{\partial T_n} \bigg|_{T_n=x} = \sum_{i=0}^{M-1} \frac{i}{2i+1} \frac{C_{2i+1}(S_M)}{(C_{1,2i+1}(S_M)x+C_{2,2i+1}(S_M))^2} \), \( x(T_n^t(t - 1), a_n, v(t)) \) denotes the solution of equation \( f_o(x) = f_e(T_n^t(t - 1)) + \frac{v^t(t)}{a_n} \), and \( v(t) \) satisfies \( \sum_{n \in \mathcal{N}} T_n^t(t) = C \).

**Proof:** Please refer to Appendix D.

**Algorithm 1** Stationary Point of Problem 2 based on CCCP

1: Initialize \( t = 1 \), \( T_n^0(1) = \frac{1}{\mathcal{N}} \) for \( n \in \mathcal{N} \), \( \epsilon = 10^{-4} \).
2: repeat
3: Obtain \( T_n^t(t + 1) \) according to Lemma 3
4: Set \( t = t + 1 \).
5: until \( q_M^{n,t+1}(T_n^t(t)) - q_M^{n,t}(T_n^t(t - 1)) < \epsilon \)

Since \( f_o(x) \) is a decreasing function, for given \( v(t) \) and \( T_n^t(t - 1), x(T_n^t(t - 1), a_n, v(t)) \) can be efficiently obtained by bisection search. In addition, since \( \sum_{n \in \mathcal{N}} T_n^t(t) \) decreases with \( v(t) \), \( v(t) \) can also be efficiently obtained by bisection search. The details for solving Problem 2 using CCCP are summarized in Algorithm 1. Different from the gradient projection method, Algorithm 1 does not rely on any stepsize. From [27], we know that Algorithm 1 converges to a stationary point of Problem 2 denoted by \( T^\dagger \). Thus, Algorithm 1 may have more robust
convergence performance than the gradient projection method. By analyzing structural properties of the stationary point $T^\dagger$ of Problem 2 obtained by Algorithm 1, we have the following result.

**Lemma 4 (Property of Stationary Point):** The stationary point $T^\dagger$ of Problem 2 obtained by Algorithm 1 satisfies $T^\dagger_1 \geq \cdots \geq T^\dagger_n$.  

**Proof:** Please refer to Appendix E.

Lemma 4 reveals that files of higher popularity get more storage resources. Fig. 4 shows $T^\dagger$ at different $M$. From Fig. 4 we can see that files of higher popularity get more storage resources, verifying Lemma 4. In addition, $T^\dagger_n$ decreases with $n$ more slowly when $M$ is larger, i.e., $T^\dagger$ becomes more flat when $M$ is larger. This is because when $M$ increases, $u_0$ can receive its desired file from the serving helper at a larger distance from $u_0$. Storing more different files (corresponding to a more flat caching distribution) can increase the STP with the MRC receiver.

2) **Performance Optimization in Low SIR Threshold Regime:** In this part, we consider the minimization of the asymptotic outage probability $q_{M,0}^{\text{mrc}}(T)$ (i.e., the maximization of the asymptotic STP) in the low SIR threshold regime.

**Problem 4 (Performance Optimization for MRC Receiver in Low SIR Threshold Regime):**

$$
\begin{align*}
& \min_T \quad q_{M,0}^{\text{mrc}}(T) \\
& \text{s.t.} \quad (1), (2).
\end{align*}
$$

Let $T^*_0 \triangleq (T^*_0, n)_{n \in \mathcal{N}}$ denote the optimal solution.

Problem 4 is a convex optimization problem and Slater’s condition is satisfied, implying that strong duality holds. Using KKT conditions, we can solve Problem 4.

**Lemma 5 (Optimal Solution of Problem 4):** The optimal solution $T^*_0$ of Problem 4 is

$$
T^*_{0,n} = \min \left\{ \frac{a_n}{\nu_0}, 1 \right\},
$$
Outage probabilities with the MRC receiver $q_{M}^{MRC}(T^\dagger)$ and $q_{M}^{MRC}(T^*_0)$ versus SIR threshold $\tau$. $N = 5$, $C = 3$, $M = 4$, $\alpha = 4$, $\lambda = 10^{-3}$, and $a_n = \sum_{n \in \mathcal{N}} n^{-\gamma}$.

where $\nu_0$ satisfies $\sum_{n \in \mathcal{N}} \min \left\{ \sqrt{\frac{a_n}{\nu_0}}, 1 \right\} = C$.

Proof: Lemma 5 can be proved in a similar way to Lemma 3. We omit the details due to page limitation.

Note that $\nu_0$ can be efficiently obtained by bisection search. From Lemma 5, we can see that $T^*_0$ is not affected by the number of receive antennas $M$. Fig. 5 plots $q_{M}^{MRC}(T^\dagger)$ and $q_{M}^{MRC}(T^*_0)$ versus the SIR threshold $\tau$ at different Zipf exponent $\gamma$. From Fig. 5, we can see that when $\tau$ decreases, the gap between each “General” curve $q_{M}^{MRC}(T^\dagger)$ and the corresponding “Asymptotic” curve $q_{M}^{MRC}(T^*_0)$ decreases. Thus, Fig. 5 verifies Lemma 5 and the optimality of $T^\dagger$ in the low SIR threshold regime.

IV. PERFORMANCE ANALYSIS AND OPTIMIZATION FOR PZF RECEIVER

In this section, we consider the performance analysis and optimization of the random caching design with the PZF receiver in the case of local CSI. First, we analyze the STP in the general SIR threshold regime. Then, we optimize the STP.

A. Performance Analysis for PZF receiver

Note that when requesting file $n$, $u_0$ can cancel the interferences from the $M - K_n$ nearest interfering helpers, using the PZF receiver parameterized by $K$. Specifically, when $\ell_{0,n} > M - K_n$, the interferences from the helpers in $\{1, 2, \cdots, M - K_n\}$ are canceled. When $\ell_{0,n} \leq M - K_n$, the interferences from the helpers in $\{1, 2, \cdots, M - K_n + 1\} \setminus \{\ell_{0,n}\}$ are canceled. By carefully handling these two scenarios, we can obtain $q_{M,n}^{pf}(K_n, T_n)$ using stochastic geometry. Substituting $q_{M,n}^{pf}(K_n, T_n)$ into (5), we have the following result.
Theorem 2 (STP with PZF Receiver in General SIR Threshold Regime): The STP with the PZF receiver parameterized by \( K \) is given by
\[
q_{M,n}^{\text{pf}}(K, T) = \sum_{n \in \mathcal{N}} a_n q_{M,n}^{\text{pf}}(K_n, T_n),
\]
where
\[
q_{M,n}^{\text{pf}}(K_n, T_n) = \begin{cases} 
(1 - T_n)^{1-M-K_n} \int_0^\infty \int_0^x g_{d_{\alpha,n},d_{M-K_n}}(T_n, x, y) \sum_{m=0}^{K_n-1} \frac{1}{m!} \sum_{k=0}^{m} \binom{m}{k} \tilde{\mathcal{L}}_I(T_n, x, x) \tilde{\mathcal{L}}_I^{m-k}(1 - T_n, x, y) dy \, dx, & \text{if } K_n < M \\
\int_0^\infty \int_0^y f_{d_{\alpha,n},d_{M-K_n+1}}(x, y) \sum_{k=0}^{K_n-1} \frac{\tilde{\mathcal{L}}_I^{m-k}(1, x, y)}{k!} dx \, dy, & \text{if } K_n = M
\end{cases}
\]
\[
g_{d_{\alpha,n},d_{j}}(T_n, x, y) = \frac{4\pi^{j+1} \lambda_n^{j+1} T_n y^{2j-1}}{(j-1)!} \exp \left(-\pi \lambda_n T_n x^2 - \pi \lambda_n (1 - T_n) y^2\right),
\]
\[
f_{d_{i},d_{j}}(x, y) = \frac{4\pi^{j} \lambda_n^i x^{2i-1} y^{2j-1}}{(i-1)!(j-i-1)!} \exp(-\pi \lambda_n y^2).
\]
Here, \( q_{M,n}^{\text{Mrc}}(T_n) \) is given by (8) and \( \tilde{\mathcal{L}}_I(T, x, y) \) is given by (10).

Proof: Please refer to Appendix F.

Note that when \( K_n = M \) for all \( n \in \mathcal{N} \), Theorem 2 reduces to Theorem 1, also verifying that the MRC receiver is a special case of the PZF receiver parameterized by \( K \). From Theorem 2, we can see that the STP \( q_{M}^{\text{pf}}(K, T) \) is an increasing function of the number of receive antennas \( M \) at each user. In particular, for \( K_n = M \), when increasing the number of receive antennas from \( M - 1 \) to \( M \) and the number of DoF for file \( n \) from \( K_n - 1 \) to \( K_n \), the increase of the STP of file \( n \) is given by (11); for \( K_n < M \), when increasing the number of receive antennas from \( M - 1 \) to \( M \) and the number of DoF for file \( n \) from \( K_n - 1 \) to \( K_n \), the increase of the STP of file \( n \) is given by
\[
q_{M,n}^{\text{pf}}(K_n, T_n) - q_{M-1,n}^{\text{pf}}(K_n - 1, T_n) = \sum_{m=1}^{M-K_n} \frac{1}{(K_n - 1)!} \int_0^\infty \int_0^y f_{d_{\alpha,n},d_{M-K_n+1}}(x, y) \tilde{\mathcal{L}}_I^{K_n-1}(1, x, y) \, dx \, dy,
\]
\[
+ \frac{(1 - T_n)^{M-K_n}}{(K_n - 1)!} \int_0^\infty \int_0^y g_{d_{\alpha,n},d_{M-K_n}}(T_n, x, y) \sum_{k=0}^{K_n-1} \frac{K_n - 1}{k} \tilde{\mathcal{L}}_I(T_n, x, x) \tilde{\mathcal{L}}_I^{K_n-1-k}(1 - T_n, x, y) \, dy \, dx > 0.
\]

In addition, from Theorem 2, we see that the impact of the physical layer parameters \( \alpha, \tau, \lambda_h \), the impact of the caching distribution \( T \) and the impact of the DoF allocation \( K \) on \( q_{M}^{\text{pf}}(K, T) \) are coupled in a very complex manner; the impact of the caching distribution \( T \) on \( q_{M}^{\text{pf}}(K, T) \) is not clear. Fig. 6 plots \( q_{M}^{\text{pf}}(K, T) \) versus \( \tau \) at different \( M \) and \( K \). From Fig. 6 we can see that each “analytical” curve closely matches the corresponding “Monte Carlo” curve. Thus, Fig. 6 verifies Theorem 2. In addition, from Fig. 6 we can see that \( q_{M}^{\text{pf}}(K, T) \) increases with \( M \).

To facilitate the characterization of the STP \( q_{M}^{\text{pf}}(K, T) \) and decouple the impacts of the caching distribution \( T \) and the physical layer parameters on \( q_{M}^{\text{pf}}(K, T) \), we then derive a tractable upper bound on \( q_{M}^{\text{pf}}(K, T) \), based on \( \text{Pr}[\text{SIR}_{n}^{\text{pf}} > \tau | \ell_{0,n} = m] > \text{Pr}[\text{SIR}_{n}^{\text{pf}} > \tau | \ell_{0,n} = k] \) for any \( k > m \) and the lower bound on the incomplete gamma function, i.e., \( (1 - e^{-S_{ab}})^a < \frac{\gamma(a,b)}{\Gamma(a)} \) [23].
The upper bound $q_{M,n}^{\text{pzf}}(K_n, T_n)$ on $q_{M}^{\text{pzf}}(K, T)$ is given below.

**Lemma 6 (Upper Bound):** The upper bound parameterized by $L \in \{1, 2, \cdots \}$ is given by

$$q_{M,n}^{\text{pzf},u}(K_n, T_n) = \sum_{n \in \mathcal{N}} a_n q_{M,n}^{\text{pzf},u}(K_n, T_n),$$

where

$$q_{M,n}^{\text{pzf},u}(K_n, T_n) = \sum_{m=1}^{M-K_n+L-1} T_n(1-T_n)^{m-1} R_{M,K_n,m} + (1-T_n)^{M-K_n+L-1} R_{M,K_n,M-K_n+L},$$

and

$$R_{M,K_n,m} = \begin{cases} f_0^\infty \int_0^y \int_{d_{m-1}}^{d_{M-K_n+1}} dx \sum_{k=1}^{K} (-1)^{k+1} L_I(1, (kS_K)^{\frac{2}{z}}, x) dy, & m \in \{1, \cdots, M-K \} \\ f_0^\infty h_{d_{M-K_n+1}}(x) \sum_{k=1}^{K} (-1)^{k+1} L_I(1, (kS_K)^{\frac{2}{z}}, x) dx, & m = M-K+1 \\ f_0^\infty \int_0^y \int_{d_{m-1}}^{d_{M-K_n+1}} dx \sum_{k=1}^{K} \left( \prod_{i=1}^{m-K+2} \frac{2n_i}{x^2-y^2} \right) \frac{1}{1+kS_K \tau \left( \frac{1}{2} \right)} dy_1 \cdots dy_m - M-K+2 dxdy, & m \in \{M-K+2, \cdots, M-K+L \} \end{cases}$$ (19)

Here, $h_{d_j}(x) \triangleq 2^{n_j} \lambda_j^2 x^{2j-1} \left( \frac{1}{j-1} \right)! \exp(-\pi \lambda_j x^2)$, $\tilde{L}_I(T, x, y)$ is given by (10) and $f_{d_i,d_j}(x,y)$ is given by (17).

**Proof:** Please refer to Appendix G.

Note that $R_{M,K_n,m}$ represents an upper bound on $\Pr [\text{SIR}_n^{\text{pzf}} > \tau | \ell_{0,n} = m]$, where $m \in \{1, \cdots, M-K_n+L \}$. Similarly, for $M \geq 2$, the impact of the physical layer parameters $\alpha$, $\tau$ and $\lambda_h$ (captured by $R_{M,K_n,m}$) and the impact of the caching distribution $T$ on $q_{M}^{\text{pzf},u}(K, T)$ are separated. Moreover, by exploring structural properties of $q_{M}^{\text{pzf},u}(K, T)$, we have the following result.

**Lemma 7 (Properties of Upper Bound):** The upper bound $q_{M}^{\text{pzf},u}(K, T)$ is a concave increasing function of the caching distribution $T$.

**Proof:** Please refer to Appendix H.
Fig. 6 plots $q_{\text{pzf},u}^p(K, T)$ and $q_{\text{pzf}}^p(K, T)$ versus $\tau$ at different $M$ and $K$. From Fig. 6, we can see that $q_{\text{pzf},u}^p(K, T)$ bounds $q_{\text{pzf}}^p(K, T)$ from above and tightly matches $q_{\text{pzf}}^p(K, T)$. In addition, the gap between $q_{\text{pzf},u}^p(K, T)$ and $q_{\text{pzf}}^p(K, T)$ decreases as $\tau$ increases. Thus, $q_{\text{pzf},u}^p(K, T)$ can serve as a good approximation for $q_{\text{pzf}}^p(K, T)$.

B. Performance Optimization for PZF Receiver

We would like to optimize $K$ and $T$ to maximize the STP with the PZF receiver. Recall that the tractable upper bound $q_{\text{pzf},u}^p(K, T)$ provides a good approximation for $q_{\text{pzf}}^p(K, T)$, as shown in Fig. 6. In addition, $q_{\text{pzf},u}^p(K, T)$ has a much simpler form than $q_{\text{pzf}}^p(K, T)$. Thus, in the following, we maximize $q_{\text{pzf},u}^p(K, T)$ instead of directly maximizing $q_{\text{pzf}}^p(K, T)$.

**Problem 5 (Performance Optimization for PZF Receiver):**

\[
\max_{K, T} q_{\text{pzf},u}^p(K, T) \\
\text{s.t. } (1), (2), (4).
\]

Let $(K^*, T^*)$ denote the optimal solution.

Since $q_{\text{pzf},u}^p(K_n, T_n)$ is an increasing function of $T_n$, by contradiction, we can easily show that files of higher popularity get more storage resources.

**Lemma 8 (Property of Optimal Solution):** The optimal solution $(K^*, T^*)$ of Problem 5 satisfies $T_1^* \geq \cdots \geq T_n^*$.

When $M = 1$, Problem 1 is a convex optimization problem, and its closed-form optimal solution is given in Theorem 4 of our previous work [8]. When $M \geq 2$, Problem 5 is a mixed discrete-continuous problem with two main challenges. One is the choice of the number of DoF allocated to boost the signal power, i.e., $K$ (discrete variables), and the other is the choice of the caching distribution of the random caching scheme, i.e., $T$ (continuous variables). We thus propose an equivalent alternative formulation of Problem 5 which naturally subdivides Problem 5 according to these two aspects.

**Problem 6 (Equivalent Problem of Problem 5):**

\[
q_{\text{pzf},u}^{*,*} = \max_K q_{\text{pzf},u}^{*,*}(K) \\
\text{s.t. } (4),
\]

where $q_{\text{pzf},u}^{*,*}(K)$ is given by

\[
q_{\text{pzf},u}^{*,*}(K) = \max_T q_{\text{pzf},u}^{*,*}(K, T) \\
\text{s.t. } (1), (2).
\]
The optimal solution to the optimization in (20) is $K^*$ and the optimal solution to the optimization in (21) is denoted as $T^*(K)$. The optimal solution to Problem 6 is given by $(K^*, T^*(K^*))$. Note that $T^*(K^*) = T^*$.

To solve Problem 6, we need to search $K$ among $M^N$ possible choices of the optimization in (20). For each possible choice of $K$, we need to obtain $T^*(K)$ by solving the convex optimization problem in (21). Thus, the brute-force optimal solution to Problem 6 using exhaustive search is not acceptable when $N$ and $M$ are large.

In the following, we obtain a low-complexity solution to Problem 6 (Problem 5) with superior performance by an alternating optimization approach. In the alternating optimization approach, the parameters $K$ and $T$ are optimized in turn while fixing the other parameter, and the procedure is repeated iteratively until $q^\text{pref, u}_{M,n}(K_n, T_n)$ cannot be improved. Specifically, at the $t$-th iteration, for given $K(t)$, we obtain the optimal solution $T(t) = T^*(K(t))$ to the convex optimization in (21), by any off-the-shelf interior-point solver (e.g., CVX [28]). Then, for given $T(t)$, we obtain the optimal solution $K(t+1)$ of the following discrete problem:

$$\max_{K} q^\text{pref, u}_{M}(K, T(t))$$
\hspace{1cm} (22)

s.t. 4.

Note that $q^\text{pref, u}_{M,n}(K_n, T_n)$ is a function of $K_n$ and is not affected by any $K_{n'}$, $n' \neq n$. Therefore, the discrete optimization in (22) can be decoupled into $N$ discrete subproblems, i.e.,

$$\max_{K_n \in M} q^\text{pref, u}_{M,n}(K_n, T_n(t)), \; n \in \mathcal{N}.\tag{23}$$

Let $K_n(t+1)$ denote the optimal solution to the discrete optimization in (23). Note that $K(t+1) = (K_n(t+1))_{n \in \mathcal{N}}$. The complexity for solving the $N$ separate subproblems in (23) is $O(MN)$. The details of the alternating optimization approach are summarized in Algorithm 2. Note that Algorithm 2 stops in a finite number of iterations (which is smaller than $M^N$) due to the increase of the STP at each iteration of the alternating optimization approach. Let $(K^\dagger, T^\dagger)$ denote the near optimal solution of Problem 5 obtained by Algorithm 2.

**Algorithm 2 Near Optimal Solution to Problem 6 (Problem 5)**

1: Initialize $t = 1$ and $K(1)$ where $K_n(1) = M - 1$ for all $n \in \mathcal{N}$.

2: repeat

3: Obtain $T(t) = T^*(K(t))$ by solving (21) with an interior-point method.

4: Obtain $K_n(t+1) = \arg\max_{K_n \in M} q^\text{pref, u}_{M,n}(K_n, T_n(t))$ for all $n \in \mathcal{N}$ by solving (23).

5: Set $t = t + 1$.

6: until $K(t) = K(t - 1)$
Fig. 7. STP with the PZF receiver versus SIR threshold $\tau$. $N = 5$, $C = 3$, $\alpha = 4$, $\lambda = 10^{-3}$, $M = 4$, $L = 3$, and $a_n = \frac{n^{-\gamma}}{\sum_{n \in N} n^{-\gamma}}$ with $\gamma = 1$.

We now use a numerical example to compare the optimal solution obtained by exhaustive search and the proposed near optimal solution obtained by Algorithm 2 in both STP and computation complexity. Fig. 7 plots the STP versus the SIR threshold $\tau$ at different $M$. We can see that the STP of the proposed near optimal solution nearly coincide with that of the optimal solution. In addition, when $M = 4$, the numbers of convex problems we need to solve for obtaining the optimal solution and the near optimal solution are $4^5 = 1024$ and at most 2, respectively. These demonstrate the applicability and effectiveness of the near optimal solution. In addition, Fig. 4 shows $T^\dagger$ obtained by Algorithm 2 at different $M$. From Fig. 4 we can see that files of higher popularity get more storage resources, and $T^\dagger_n$ decreases with $n$ more slowly when $M$ is larger, i.e., $T^\dagger$ becomes more flat when $M$ is larger.

V. NUMERICAL RESULTS

In this section, we compare the proposed random caching designs with the PZF and MRC receivers with three baseline schemes [5]–[7]. Baseline 1 (most popular) adopts the caching design in which each helper selects the $C$ most popular files to store, i.e., $T_n = 1$ for $n \in \{1, \cdots, C\}$ and $T_n = 0$ for $n \in \{C+1, \cdots, N\}$ [5]. Baseline 2 (i.i.d. file popularity) adopts the caching design in which each helper randomly selects $C$ files to store in an i.i.d. manner with file $n$ being selected with probability $a_n$ [7]. Baseline 3 (uniform dist.) adopts the caching design in which each helper randomly selects $C$ different files to store, according to the uniform distribution, i.e., $T_n = \frac{C}{N}$ for all $n \in N$ [6]. The three baseline schemes all consider the MRC receiver as in the proposed random caching design with the MRC receiver. In the simulation, the popularity follows the Zipf distribution, i.e., $a_n = \frac{n^{-\gamma}}{\sum_{n \in N} n^{-\gamma}}$, where $\gamma$ is the Zipf exponent. We choose $N = 100$, $\tau = 1$ and $\lambda = 10^{-3}$.
Fig. 8. STP versus number of receive antennas $M$, cache size $C$, pathloss exponent $\alpha$ and Zipf exponent $\gamma$.

Fig. 8 plots the STP versus $M$, $C$, $\alpha$ and $\gamma$. We can observe that the proposed designs with the MRC and PZF receivers outperform all the three baseline schemes. This is because the proposed designs can wisely exploit the storage resource. In addition, the proposed design with the PZF receiver outperforms the proposed design with the MRC receiver. This is due to the fact that the proposed design with the PZF receiver can also wisely exploit antenna resource besides storage resource. The STP gap between the two proposed designs is relatively large at large number of receive antennas $M$, large cache size $C$, large pathloss exponent $\alpha$ and small Zipf exponent $\gamma$. This demonstrates the significant benefit of making good use of antenna resource in these regions.

Specifically, from Fig. 8 (a), we can see that the STP of each of the five schemes increases with $M$. This is because the receive signal power increases with $M$ for the MRC receiver, and the receive signal power increases or the interference power decreases with $M$ for the PZF receiver. From Fig. 8 (b), we can see that the STP of each of the five schemes increases with $C$. This is due to the fact that as $C$ increases, each helper can store more files, and the average distance
between a user and its serving helper decreases. From Fig. 8 (c), we can see that the STP of each of the five schemes increases with $\alpha$. This is because as $\alpha$ increases, the attenuation of the receive signal power is relatively smaller than that of the interference power. From Fig. 8 (d), we can see that the STP of each scheme except Baseline 3 increases with $\gamma$. This is because as $\gamma$ increases, the tail of the popularity distribution becomes small, and a randomly requested file by a user is stored at a nearby helper with a higher probability under popularity-aware caching designs.

VI. CONCLUSION

In this paper, we considered random caching at helpers and MRC and PZF receivers at users in a large-scale cache-enabled SIMO network. First, we analyzed the STP. For each receiver, we derived a tractable expression and a tight upper bound for the STP. The analytical results showed that for each receiver, the STP increases with the number of receive antennas $M$. Then, for each receiver, we considered the STP maximization via maximizing the tight upper bound on the STP. In the case of the MRC receiver, the optimization problem is non-convex, and we obtained a stationary point by solving an equivalent DC programming problem using CCCP. In the case of the PZF receiver, the optimization problem is a mixed discrete-continuous problem, and we obtained a low-complexity near optimal solution by an alternating optimization approach. The optimization results indicated that files of higher popularity get more storage resources, and the optimized caching distribution becomes more flat when $M$ is larger.

APPENDIX A: PROOF OF THEOREM

First, we calculate the STP of file $n$:

$$q_{M,n}(T_n) = \Pr[SIR_n \geq \tau] = \int_0^\infty \Pr[SIR_n \geq \tau | d_{\ell_0,n} = x] f_{d_{\ell_0,n}}(x) dx,$$

where $f_{d_{\ell_0,n}}(x)$ denotes the probability density function (pdf) of random variable $d_{\ell_0,n}$. Note that we have $f_{d_{\ell_0,n}}(x) = 2\pi \lambda h T_n x \exp(-\pi \lambda h T_n x^2)$, as the helpers storing file $n$ form a homogeneous PPP with density $\lambda h T_n$. To calculate $q_{M,n}(T_n)$, it remains to calculate $\Pr[SIR_n \geq \tau | d_{\ell_0,n} = x]$.

We rewrite $SIR_n = \frac{H_{\ell_0,n} d_{\ell_0,n}^{-\alpha}}{I_n + I_{-n}}$, where $I_n \triangleq \sum_{i \in \Phi_{h,n} \setminus \{\ell_0,n\}} H_{i,0} d_i^{-\alpha}$ and $I_{-n} \triangleq \sum_{i \in \Phi_{h,-n}} H_{i,0} d_i^{-\alpha}$. Here, $\Phi_{h,n}$ denotes the point process generated by helpers storing file $n$ and $\Phi_{h,-n} \triangleq \Phi_h \setminus \Phi_{h,n}$. Due to independent thinning, point processes $\Phi_{h,n}$ and $\Phi_{h,-n}$ are two independent homogeneous PPPs with density $\lambda h T_n$ and $\lambda h (1 - T_n)$, respectively. Therefore, we have:

$$\Pr[SIR_n \geq \tau | d_{\ell_0,n} = x] = \Pr[H_{\ell_0,n} \geq s(I_n + I_{-n})] \overset{(a)}{=} \mathbb{E}_{I_n,I_{-n}} \left[ \exp(-s(I_n + I_{-n})) \sum_{m=0}^{M-1} \frac{s^m (I_n + I_{-n})^m}{m!} \right]$$
where \( s = \tau x^\alpha \), (a) is due to \( H_{t,0,0}^{\text{mc}} \overset{d}{\sim} \Gamma(M, 1) \), and \( \mathcal{L}_I^{(k)}(s) \equiv \mathbb{E}_I \left[ (-I)^k \exp (-sI) \right] \) denotes the \( n \)-th order derivative of the Laplace transform of random variable \( I \), i.e., \( \mathcal{L}_I(s) \equiv \mathbb{E}_I \left[ \exp (-sI) \right] \).

Then, we calculate \( \mathcal{L}_{I,n}^{(k)}(s) \) and \( \mathcal{L}_{I,n}^{(k)}(s) \), respectively. \( \mathcal{L}_{I,n}(s) \) can be calculated as follows.

\[
\mathcal{L}_{I,n}(s) = \mathbb{E}_{\Phi_{h,n}(H_{t,0}^{\text{mc}})} \left[ \exp \left( -s \sum_{i \in \Phi_{h,n} \setminus \{t,0\}} H_{t,0}^{\text{mc}} d_i^{-\alpha} \right) \right] = \mathbb{E}_{\Phi_{h,n}} \left[ \prod_{i \in \Phi_{h,n} \setminus \{t,0\}} \mathbb{E}_{H_{t,0}^{\text{mc}}} \left[ \exp \left( -sH_{t,0}^{\text{mc}} d_i^{-\alpha} \right) \right] \right]
\]

\[
\overset{(b)}{=} \mathbb{E}_{\Phi_{h,n}} \left[ \prod_{i \in \Phi_{h,n} \setminus \{t,0\}} \frac{1}{1 + sd_i^{-\alpha}} \right] \overset{(c)}{=} \exp \left( -\pi \lambda h T_n j \int_0^\infty \left( 1 - \frac{1}{1 + s r^{-\alpha}} \right) r dr \right)
\]

\[
\overset{(d)}{=} \exp \left( -\frac{\pi \lambda h T_n s^{\frac{\alpha}{\alpha - 1}}}{\alpha} B^\prime \left( \frac{2}{\alpha}, 1 - \frac{2}{\alpha}, \frac{1}{1 + \tau} \right) \right),
\]

where (b) is due to \( H_{t,0}^{\text{mc}} \overset{d}{\sim} \text{Exp}(1) \), (c) is obtained by using the probability generating functional of a PPP, (d) is obtained by first replacing \( s^{-\frac{1}{\alpha}} r \) with \( t \) and then replacing \( \frac{1}{1 + t^{-\alpha}} \) with \( w \). Similar to \( \mathcal{L}_{I,n}(s) \), we have

\[
\mathcal{L}_{I,n}(s) = \exp \left( -\frac{\pi \lambda h (1 - T_n) s^{\frac{\alpha}{\alpha - 1}}}{\alpha} B^\prime \left( \frac{2}{\alpha}, 1 - \frac{2}{\alpha} \right) \right).
\]

Based on (26) and utilizing Faà di Bruno’s formula, \( \mathcal{L}_{I,n}^{(k)}(s) \) can be calculated as follows.

\[
\mathcal{L}_{I,n}^{(k)}(s) = \mathcal{L}_{I,n}(s) \sum_{(b_j)_{j=1}^k \in \mathcal{M}_k} \frac{k!}{b_1! b_2! \ldots b_k!} \prod_{j=1}^k \left( \frac{2\pi \lambda h T_n}{j!} \int_x^\infty \frac{d^j}{ds^j} \left( \frac{1}{1 + s r^{-\alpha}} \right) r dr \right)^{b_j}
\]

\[
\overset{(c)}{=} \left( -1 \right)^k \mathcal{L}_{I,n}(s) \sum_{(b_j)_{j=1}^k \in \mathcal{M}_k} \frac{k!}{b_1! b_2! \ldots b_k!} \prod_{j=1}^k \left( \frac{2\pi \lambda h T_n}{j!} \int_x^\infty \frac{r^{-j+\alpha+1}}{(1 + s r^{-\alpha})^{j+1}} dr \right)^{b_j}
\]

\[
\overset{(d)}{=} \left( -\frac{1}{s} \right)^k \mathcal{L}_{I,n}(s) \sum_{(b_j)_{j=1}^k \in \mathcal{M}_k} \frac{k!}{b_1! b_2! \ldots b_k!} \prod_{j=1}^k \left( \frac{2\pi \lambda h (1 - T_n) s^{\frac{\alpha}{\alpha - 1}} B^\prime \left( \frac{2}{\alpha}, 1 + j - \frac{2}{\alpha}, \frac{1}{1 + \tau} \right)}{\alpha} \right)^{b_j},
\]

where (e) is due to \( \frac{d^j}{ds^j} \frac{1}{1 + s r^{-\alpha}} = \left( -\frac{1}{s} \right)^j \frac{r^{-j+\alpha}}{(1 + s r^{-\alpha})^{j+1}} \) and \( \prod_{j=1}^k \left( -1 \right)^j b_j = \left( -1 \right)^{\sum_{j=1}^k j b_j} = \left( -1 \right)^k \), and (f) is obtained by first replacing \( s^{-\frac{1}{\alpha}} r \) with \( t \) and then replacing \( \frac{1}{1 + t^{-\alpha}} \) with \( w \). Similar to \( \mathcal{L}_{I,n}^{(k)}(s) \), we have

\[
\mathcal{L}_{I,n}^{(k)}(s) = \left( -\frac{1}{s} \right)^k \mathcal{L}_{I,n}(s) \sum_{(b_j)_{j=1}^k \in \mathcal{M}_k} \frac{k!}{b_1! b_2! \ldots b_k!} \prod_{j=1}^k \left( \frac{2\pi \lambda h (1 - T_n) s^{\frac{\alpha}{\alpha - 1}} B^\prime \left( \frac{2}{\alpha}, 1 + j - \frac{2}{\alpha} \right)}{\alpha} \right)^{b_j}.
\]

Finally, substituting (28) and (29) into (25), we have

\[
\Pr \left[ \text{SIR}_n^{\text{mc}} \geq \tau | d_{t,0,n} = x \right] = \sum_{m=0}^{M-1} \frac{1}{m!} \sum_{k=0}^{m} \binom{m}{k} \mathcal{L}_{I,n}^{(k)}(s) \mathcal{L}_{I,n}^{(m-k)}(s),
\]
where \( \tilde{L}^{(k)}_I(s) \triangleq L^{(k)}_I(s)/(-\frac{1}{s})^k \) and \( \tilde{L}^{(k)}_{I^{-}}(s) \triangleq L^{(k)}_{I^{-}}(s)/(-\frac{1}{s})^k \). Substituting (30) into (24), we can obtain \( q^{\text{mc}}_{M,n}(T_n) \). According to total probability theorem, we complete the proof of Theorem 1.

APPENDIX B: PROOF OF LEMMA 1

We obtain an upper bound on the STP of file \( n \) as follows.

\[
q^{\text{mc}}_{M,n}(T_n) = 1 - \int_0^\infty \Pr [\text{SIR}^{\text{mc}}_n < \tau | d_{I_{0,n}} = x] f_{d_{I_{0,n}}}(x)dx \overset{(a)}{=} 1 - \int_0^\infty \mathbb{E}_{I_n,I_{-n}} \left[ \frac{\gamma(M,s(I_n + I_{-n}))}{\Gamma(M)} \right] f_{d_{I_{0,n}}}(x)dx \\
< 1 - \int_0^\infty \mathbb{E}_{I_n,I_{-n}} \left[ (1 - \exp(-S_M s(I_n + I_{-n})))^M \right] f_{d_{I_{0,n}}}(x)dx \\
= 1 - \int_0^\infty \mathbb{E}_{I_n,I_{-n}} \left[ \sum_{k=0}^M \binom{M}{k} (-1)^k \exp(-kS_M s(I_n + I_{-n})) \right] f_{d_{I_{0,n}}}(x)dx \\
= 1 - \sum_{k=0}^M \binom{M}{k} (-1)^k \int_0^\infty L_n(kS_M s)L_{I_{-n}}(kS_M s) f_{d_{I_{0,n}}}(x)dx \overset{(b)}{=} q^{\text{mc},n}_{M,n}(T_n),
\]

(31)

where (a) is due to \( H^{\text{mc},0}_{I_{0,n}} \overset{d}{\sim} \text{Gamma}(M,1) \) and (b) is based on a lower bound on the incomplete gamma function, i.e., \( (1 - e^{-S_a b})^a < \frac{\gamma(a,b)}{\Gamma(a)} \) for \( a > 1 \). Note that \( L_n(kS_M s) \) and \( L_{I_{-n}}(kS_M s) \) are given by (26) and (27), respectively. Substituting (26) and (27) into (31), we have

\[
q^{\text{mc},n}_{M,n}(T_n) = 1 - \sum_{k=0}^M \binom{M}{k} (-1)^k 2\pi \lambda_h T_n \int_0^\infty x \exp(-\pi \lambda_h T_n + A)x^2)dx \overset{(c)}{=} 1 - \sum_{k=0}^M \binom{M}{k} (-1)^k \frac{\pi \lambda_h T_n}{\pi \lambda_h T_n + A},
\]

where \( A \triangleq \frac{2}{\alpha} (kS_M \tau) \hat{\beta} B' \left( \frac{2}{\alpha}, 1 - \frac{1}{1 + kS_M \tau} \right) + \frac{2}{\alpha} (\frac{1}{T_n} - 1)(kS_M \tau) \hat{\beta} B \left( \frac{2}{\alpha}, 1 - \frac{2}{\alpha} \right) \) and (c) is due to \( \int_0^\infty x \exp(-cx^2)dx = \frac{1}{\sqrt{c}} \). After some algebraic manipulations, we can obtain \( q^{\text{mc},n}_{M,n}(T_n) \) and the corresponding upper bound \( q^{\text{mc},n}_{M,n}(T) \) on \( q^{\text{mc}}_{M,n}(T_n) \).

APPENDIX C: PROOF OF LEMMA 2

First, we calculate the conditional outage probability of file \( n \) conditioned on \( d_{I_{0,n}} = x \). Similar to the calculation of \( \Pr [\text{SIR}^{\text{mc}}_n \geq \tau | d_{I_{0,n}} = x] \) in Appendix A, we have

\[
\Pr [\text{SIR}^{\text{mc}}_n < \tau | d_{I_{0,n}} = x] = \Pr [H^{\text{mc},0}_{I_{0,n}} < s(I_n + I_{-n})] \overset{(a)}{=} \mathbb{E}_{I_n,I_{-n}} \left[ \exp(-s(I_n + I_{-n})) \sum_{m=M}^{\infty} \frac{s^m(I_n + I_{-n})^m}{m!} \right] \\
= \sum_{m=M}^{\infty} \frac{(-s)^m}{m!} \sum_{k=0}^m \binom{m}{k} \tilde{L}^{(k)}_I(s) \tilde{L}^{(m-k)}_{I_{-n}}(s) = \sum_{m=M}^{\infty} \frac{1}{m!} \sum_{k=0}^m \binom{m}{k} \tilde{L}^{(k)}_I(s) \tilde{L}^{(m-k)}_{I_{-n}}(s),
\]

where (a) is due to \( H^{\text{mc},0}_{I_{0,n},0} \overset{d}{\sim} \text{Gamma}(M,1) \). Then, by removing the condition of \( \Pr [\text{SIR}^{\text{mc}}_n < \tau | d_{I_{0,n}} = x] \) on \( d_{I_{0,n}} = x \), we obtain the outage probability of file \( n \):

\[
\overline{q}^{\text{mc}}_{M,n}(T_n) = \int_0^\infty f_{d_{I_{0,n}}}(x) \sum_{m=M}^{\infty} \frac{1}{m!} \sum_{k=0}^m \binom{m}{k} \tilde{L}^{(k)}_I(s) \tilde{L}^{(m-k)}_{I_{-n}}(s)dx.
\]

Next, we calculate the asymptotic outage probability of file \( n \) in the low SIR threshold regime, i.e., \( \lim_{\tau \to 0} \overline{q}^{\text{mc}}_{M,n}(T_n) \). According to dominated convergence theorem, we have:

\[
\lim_{\tau \to 0} \overline{q}^{\text{mc}}_{M,n}(T_n) = \lim_{\tau \to 0} \int_0^\infty f_{d_{I_{0,n}}}(x) \sum_{m=M}^{\infty} \frac{1}{m!} \sum_{k=0}^m \binom{m}{k} \tilde{L}^{(k)}_I(s) \tilde{L}^{(m-k)}_{I_{-n}}(s)dx
\]
\[
= \int_0^\infty \lim_{\tau \to 0} f_{d_{i_0,n}}(x) \sum_{m=M}^{\infty} \frac{1}{m!} \sum_{k=0}^{m} \binom{m}{k} L_{\tau}^{(k)}(s) \tilde{L}_{\tau}^{(m-k)}(s) dx. \tag{32}
\]

We note that \( B'(a, b, z) = \frac{(1-z)^b}{b} + o\left((1-z)^b\right) \) as \( z \to 1 \). Then, as \( \tau \to 0 \), we have \( B'\left(\frac{2}{\alpha}, 1 - \frac{2}{\alpha}, \frac{1}{1+\tau}\right) = \frac{2}{\alpha} + o\left(\frac{1}{\alpha}\right) \) and \( B'\left(1 + \frac{2}{\alpha}, a - \frac{2}{\alpha}, \frac{1}{1+\tau}\right) = \frac{(a-2)^b}{b} + o\left(\frac{1}{\alpha}\right) \). Based on these two asymptotic expressions, as \( \tau \to 0 \), we have:

\[
L_{\tau}^{(k)}(s) = \tau^k \left( \sum_{(b)_j \in \mathcal{M}_k} \frac{k!}{b_1!b_2! \cdots b_k!} \prod_{j=1}^{k} \left( \frac{2 \pi \lambda h T_n x^2}{\alpha} \right)^{b_j} + o(\tau^k) \right). \tag{33}
\]

On the other hand, as \( \tau \to 0 \), we have

\[
L_{\tau}^{(k)}(s) = L_{\tau}^{-n}(s) \sum_{(b)_j \in \mathcal{M}_k} \tau^\frac{\alpha}{2} \sum_{j=1}^{n} \frac{k!}{b_1!b_2! \cdots b_k!} \prod_{j=1}^{k} \left( \frac{2 \pi \lambda h (1 - T_n x^2)}{\alpha} B \left(2 \frac{2}{\alpha} + 1, k - \frac{2}{\alpha}\right) + o(\tau^\frac{\alpha}{2}) \right) \tag{34}
\]

where (a) is due to the fact that \( b_1 = \cdots = b_{k-1} = 0 \) and \( b_k = 1 \) is the dominant term in \( \sum_{(b)_j \in \mathcal{M}_k} \tau^\frac{\alpha}{2} \sum_{j=1}^{n} \) as \( \tau \to 0 \). Substituting (33) and (34) into (32), we have

\[
\lim_{\tau \to 0} \tau^{\frac{\alpha}{2}} \mathcal{T}_{M,n}(T_n) = \sum_{m=M}^{\infty} \frac{1}{m!} \sum_{k=0}^{m} \binom{m}{k} \tau^{k+\frac{\alpha}{2}} \int_0^\infty f_{d_{i_0,n}}(x) \left( \sum_{(b)_j \in \mathcal{M}_k} \frac{k!}{b_1!b_2! \cdots b_k!} \prod_{j=1}^{k} \left( \frac{2 \pi \lambda h T_n x^2}{\alpha} \right)^{b_j} \right) dx + o(\tau^{k+\frac{\alpha}{2}}), \tag{35}
\]

where (b) is due to the fact that \( k = 0 \) is the dominant term in \( \sum_{k=0}^{m} \tau^{k+\frac{\alpha}{2}} \) as \( \tau \to 0 \).

Finally, based on (35), we have \( \lim_{\tau \to 0} \mathcal{T}_{M,n}(T_n) = \mathcal{T}_{M,0}(T) + o(\tau^{\frac{\alpha}{2}}) \).

**APPENDIX D: PROOF OF LEMMA 5**

The Lagrangian function of Problem 3 is given by

\[
L(T, \eta, \lambda, v) = R_0(T) + \sum_{n \in N} a_n f_c(T_n(t-1)) T_n - \sum_{n \in N} \eta_n T_n + \sum_{n \in N} \lambda_n (T_n - 1) + v \left( \sum_{n \in N} T_n - C \right),
\]

where \( \eta \triangleq (\eta_n)_{n \in N} \) and \( \lambda \triangleq (\lambda_n)_{n \in N} \) are the Lagrange multipliers associated with the inequality constraints \( T_n \geq 0, n \in N \) and \( T_n \leq 1, n \in N \), respectively. \( v \) is the Lagrange multiplier associated with the equality constraint \( \sum_{n \in N} T_n = C \). Thus, we have

\[
\frac{\partial L(T, \eta, \lambda, v)}{\partial T_n} = -a_n f_c(T_n) + a_n f_c(T_n(t-1)) - \eta_n + \lambda_n + v.
\]

Since strong duality holds, primal optimal \( T^*(t) \) and dual optimal \( \eta^*, \lambda^* \) and \( v^*(t) \) satisfy KKT conditions: (i) primal constraints (1) and (2); (ii) dual constraints \( \eta_n \geq 0 \) and \( \lambda_n \geq 0 \) for all \( n \in N \); (iii) complementary slackness \( \eta_n T_n = 0 \) and \( \lambda_n (T_n - 1) = 0 \) for all \( n \in N \); and (iv)
\[
\frac{\partial L(T, n, \lambda, v)}{\partial T_n} = 0. \text{ By (i)-(iv), we have the following results: if } v > a_n(f_o(0) - f_e(T_n^t(t-1))), \text{ then } T_n = 0; \text{ if } v < a_n(f_o(1) - f_e(T_n^t(t-1))), \text{ then } T_n = 1; \text{ if } a_n(f_o(1) - f_e(T_n^t(t-1))) < v < a_n(f_o(0) - f_e(T_n^t(t-1))), \text{ then } T_n \text{ satisfies } f_o(T_n) = f_e(T_n(t-1)) + \frac{v}{a_n}. \text{ Combining with (2), we can prove Lemma 3.}
\]

**APPENDIX E: PROOF OF LEMMA 4**

We prove Lemma 4 by mathematical induction. First, according to the initialization, we have \( T_n^+(1) = T_n^-(1) = \frac{C}{N} \) for all \( n' > n \). Assume \( T_n^+(t) \geq T_n^-(t) \) for all \( n' > n \), where \( t \geq 1 \). Next, we show \( T_n^+(t+1) \geq T_n^-(t+1) \) for all \( n' > n \). Since \( a_n > a_{n'} \) and \( T_n^+(t) \geq T_n^-(t) \) for all \( n' > n \), and \( f_e(x) \) is a decreasing function, we have \( f_e(T_n^+(t)) + \frac{v(t+1)}{a_n} < f_e(T_n^-(t)) + \frac{v(t+1)}{a_n} \). Combining with the fact that \( f_o(x) \) is a decreasing function, we have (i) if \( f_o(0) \leq f_e(T_n^+(t)) + \frac{v(t+1)}{a_n} \), then \( T_n^+(t+1) \geq T_n^-(t+1) = 0 \); (ii) if \( f_o(1) \geq f_e(T_n^+(t)) + \frac{v(t+1)}{a_n} \), then \( T_n^+(t+1) \leq T_n^-(t+1) = 1 \); (iii) if \( f_o(1) < f_e(T_n^+(t)) + \frac{v(t+1)}{a_n} < f_e(T_n^-(t)) + \frac{v(t+1)}{a_n} < f_o(0) \), then \( 0 < T_n^+(t+1) < T_n^-(t+1) < 1 \). Therefore, we can show Lemma 4.

**APPENDIX F: PROOF OF THEOREM 2**

When \( K_n = M \), the PZF receiver reduces to the MRC receiver and \( q_{M,n}^{PZF}(K_n, T_n) = q_{M,n}^{MRC}(T_n) \). When \( K_n < M \), by the law of total probability, we have

\[
q_{M,n}^{PZF}(K_n, T_n) = \Pr[\ell_{0,n} > M - K_n] \Pr[SIR_n^{PZF} > \tau|\ell_{0,n} > M - K_n]
+ \sum_{m=1}^{M-K_n} \Pr[\ell_{0,n} = m] \Pr[SIR_n^{PZF} > \tau|\ell_{0,n} = m], \tag{36}
\]

where \( \Pr[\ell_{0,n} = m] = T_n(1-T_n)^{-m-1} \) and \( \Pr[\ell_{0,n} > m] = (1-T_n)^{-m-1} \). To calculate \( q_{M,n}^{PZF}(K_n, T_n) \), it remains to calculate \( \Pr[SIR_n^{PZF} > \tau|\ell_{0,n} = m] \) and \( \Pr[SIR_n^{PZF} > \tau|\ell_{0,n} > M - K_n] \).

When \( \ell_{0,n} > M - K_n \), we have

\[
\Pr[SIR_n^{PZF} > \tau|\ell_{0,n} > M - K_n] = \int_0^\infty \int_0^x g_{d_{\ell_{0,n}}}(m, \alpha, \gamma, \nu) \Pr\left[\frac{H_{0,0}^{PZF} d_{\ell_{0,n}}^{\alpha}}{I_n + I_{-n}} > \tau \left| d_{\ell_{0,n}} = x, d_{M-K_n} = y \right.\right] \, d\gamma \, dx,
\]

where \( I_n \triangleq \sum_{i \in \Phi_h, n \setminus \{\ell_{0,n}\}} (H_{0,0}^{PZF} d_{0,0}^{\alpha})_i + I_{-n} \triangleq \sum_{i \in \Phi_h, -n \setminus \{1, 2, \ldots, M-K_n\}} (H_{0,0}^{PZF} d_{0,0}^{\alpha})_i \) denotes the joint pdf of \( d_{\ell_{0,n}} \) and \( d_{M-K_n} \) when \( \ell_{0,n} > M - K_n \). Similar to the calculation of \( \Pr[SIR_n^{MRC} > \tau|d_{\ell_{0,n}} = x] \) in (25) in Appendix A, we have

\[
\Pr\left[\frac{H_{0,0}^{PZF} d_{(m,0)}^{\alpha}}{I_n + I_{-n}} > \tau \left| d_{\ell_{0,n}} = x, d_{M-K_n} = y \right.\right] = \sum_{m=0}^{K_n-1} \sum_{k=0}^{m} \frac{m!}{k!} \binom{m}{k} \tilde{L}_m^k(T_n, x, y) \tilde{L}_m^{m-k}(1-T_n, x, y). \tag{37}
\]

Now, we calculate \( g_{d_{\ell_{0,n}}}(m, \alpha, \gamma, \nu) \). Note that the pdf of the distance of the \( i \)-th nearest
point in a homogeneous PPP with density $\lambda$ is $h_d(x, \lambda) = 2 \pi^2 \lambda x^{2 \lambda - 1} \exp(-\pi \lambda x^2)$. Due to the independence between $\Phi_{h,n}$ and $\Phi_{h,-n}$, we have

$$g_{d_{0,n},d_{M-K,n}}(T_n, x, y) = \frac{h_d(x, \lambda_h T_n) h_{d_{M-K,n}}(y, \lambda_h (1 - T_n))}{\Pr[\ell_{0,n} > M - K_n]}.$$  \hfill (39)

When $\ell_{0,n} = m \in \{1, 2, \cdots, M - K_n\}$, we have

$$\Pr[SIR^\text{ref}_n > \tau | \ell_{0,n} = m] = \int_0^\infty \int_0^y f_{d_{m},d_{M-K,n+1}}(x, y) \Pr \left[ \frac{H_{m,0}^{\text{ref}} R_1^{\alpha}}{I} > \tau | d_m = x, d_{M-K,n+1} = y \right] \, dx \, dy,$$  \hfill (40)

where $I_2 \triangleq \sum_{i \in \Phi_{h}\setminus\{1, \cdots, M-K_n+1\}} H_{i,0}^{\text{ref}} d_{i}^{-\alpha}$ and $f_{d_{m},d_{M-K,n+1}}(x, y)$ denotes the joint pdf of $d_m$ and $d_{M-K,n+1}$ when $m < M - K_n + 1$. Similar to the calculation of $\Pr[SIR^\text{mic}_n \geq \tau | d_{0,n} = x]$ in (25) in Appendix A, we have

$$\Pr \left[ \frac{H_{m,0}^{\text{ref}} R_1^{\alpha}}{I} > \tau | d_m = x, d_{M-K,n+1} = y \right] = \sum_{m=0}^{K_n-1} \frac{1}{m!} \sum_{k=0}^{m} \binom{m}{k} \tilde{L}_k^k(T_n, x, x) \tilde{L}_k^m(1 - T_n, x, y).$$  \hfill (41)

Now, we calculate $f_{d_{m},d_{M-K,n+1}}(x, y)$. Consider four non-overlapping areas $A_1 = B(0, d_m) \setminus A_2 = B(0, d_m + dr_1) \setminus B(0, d_m) \setminus A_3 = B(0, d_{M-K,n+1} + dr_1) \setminus B(0, d_m) \setminus A_4 = B(0, d_{M-K,n+1} + dr_1) \setminus B(0, d_{M-K,n+1})$, where $B(0, d)$ denotes the ball centered at the origin with radius $d$. According to the definition of PPP, the joint probability that nodes $m$ and $M - K_n + 1$ belong to $A_2$ and $A_4$, respectively, is given by

$$\Pr[\text{node } m \text{ in } A_2, \text{ node } M - K_n + 1 \text{ in } A_4] = \begin{cases} P_1 P_2 P_3 P_4 & d_m \leq d_{M-K,n+1} \\ 0 & \text{otherwise} \end{cases},$$  \hfill (42)

where $P_1 = \Pr[m - 1 \text{ nodes in } A_1] = \frac{(\pi \lambda h d_m^2)^{m-1}}{(m-1)!} \exp(-\pi \lambda h d_m^2)$, $P_2 = \Pr[1 \text{ node in } A_2] = \pi \lambda h ((d_m + dr_1)^2 - d_m^2) \exp(-\pi \lambda h ((d_m + dr_1)^2 - d_m^2))$, $P_3 = \Pr[M - K_n - m \text{ nodes in } A_3] = \frac{(\pi \lambda h (d_{M-K,n+1} + dr_1)^2 - d_{M-K,n+1}^2)) \exp(-\pi \lambda h ((d_{M-K,n+1} + dr_1)^2 - d_{M-K,n+1}^2))}{(M-K_n-m)!}$ and $P_4 = \Pr[1 \text{ node in } A_4] = \pi \lambda h ((d_{M-K,n+1} + dr_2)^2 - d_{M-K,n+1}^2) \exp(-\pi \lambda h ((d_{M-K,n+1} + dr_2)^2 - d_{M-K,n+1}^2))$. By (42), we have

$$f_{d_{m},d_{M-K,n+1}}(x, y) = \lim_{dr_1, dr_2 \to 0} \frac{\Pr[\text{node } m \text{ in } A_2, \text{ node } M - K_n + 1 \text{ in } A_4]}{dr_1 dr_2} = \begin{cases} \frac{4(\pi \lambda h)^{M-K_n+1} d_m^{2m-1} d_{M-K,n+1}((d_m^2 - d_{M-K,n+1}^2) \exp(-\pi \lambda h d_m^2))}{(m-1)! (M-K_n-m)!} & d_m < d_{M-K,n+1} \\ 0 & \text{otherwise} \end{cases}.$$  \hfill (43)

Substituting (38) and (39) into (37) and substituting (41) and (43) into (40), we can obtain $\Pr[SIR^\text{ref}_n > \tau | \ell_{0,n} = m]$ and $\Pr[SIR^\text{ref}_n > \tau | \ell_{0,n} > M - K_n]$, respectively. Then, based on (36), we can obtain $q_{M,n}^\text{ref}(K_n, T_n)$. According to total probability theorem, we can show Theorem 2.

Appendix G: Proof of Lemma 6

By the law of total probability, we have
where (a) is due to \( \Pr \left[ \text{SIR}^{\text{ref}}_n > \tau | \ell_{0,n} = m \right] \leq \sum_{m=1}^{M-K_n+L-1} \Pr \left[ \ell_{0,n} = m \right] \Pr \left[ \text{SIR}^{\text{ref}}_n > \tau | \ell_{0,n} = m \right] \\
+ \sum_{m=M-K_n+L}^{\infty} \Pr \left[ \ell_{0,n} = m \right] \Pr \left[ \text{SIR}^{\text{ref}}_n > \tau | \ell_{0,n} = M - K_n + L \right], \\
(b) \sum_{m=1}^{M-K_n+L-1} T_n (1-T_n)^{m-1} R_{M,K_n,m} + (1-T_n)^{M-K_n+L-1} R_{M,K_n,M-K_n+L}
\]

where (a) is due to \( \Pr \left[ \text{SIR}^{\text{ref}}_n > \tau | \ell_{0,n} = m \right] > \Pr \left[ \text{SIR}^{\text{ref}}_n > \tau | \ell_{0,n} = k \right] \) for any \( k > m \), (b) is due to the fact that \( R_{M,K_n,m} \) is an upper bound on \( \Pr \left[ \text{SIR}^{\text{ref}}_n > \tau | \ell_{0,n} = m \right] \) obtained by adopting the lower bound on the incomplete gamma function, i.e., \( (1 - e^{-S_0 b})^a < \frac{\gamma(a,b)}{T(a)} \). \( R_{M,K_n,m} \) can be calculated in a similar way to \( q_{M,n}^{\text{ref},u} (T_n) \) in Lemma 6. We omit the details due to page limitation. Therefore, we complete the proof of Lemma 6.

APPENDIX H: PROOF OF LEMMA 7

By denoting \( P_n = 1 - T_n \), we have
\[
q_{M,n}^{\text{ref},u} (K_n, 1 - P_n) = \sum_{m=1}^{M-K_n+L-1} (1-P_n) P_n^{m-1} R_{M,K_n,m} + P_n^{M-K_n+L-1} R_{M,K_n,M-K_n+L}
\]
\[
= R_{M,K_n,1} - \sum_{m=1}^{M-K_n+L-1} P_n^m (R_{M,K_n,m} - R_{M,K_n,m+1}).
\]

Since \( R_{M,K_n,m} - R_{M,K_n,m+1} > 0 \), \( q_{M,n}^{\text{ref},u} (K_n, 1 - P_n) \) is a decreasing function of \( P_n \). In addition, since \( q_{M,n}^{\text{ref},u} (K_n, 1 - P_n) \) is not affected by any \( P_{n'}, n' \neq n \), \( \frac{d^2 q_{M,n}^{\text{ref},u}(K_n, 1-P_n)}{d P_n^2} < 0 \), \( q_{M,n}^{\text{ref},u} (K, 1-P) \) is a concave function of \( P \). Therefore, \( q_{M,n}^{\text{ref},u} (K, T) \) is a concave increasing function of \( T \).
