DOI: http://dx.doi.org/10.33545/26644436.2021.v4.i2a.192

Abstract
Doppler ultrasound evaluation of the mother and fetus with the study of blood flow indices provides non-invasive assessment to study uteroplacental circulation and fetoplacental circulation and hemodynamic changes and adaptation in the fetal organs in response to hypoxemia; with this, the degree of placental dysfunction can be studied to know the severity of the disease. The study was conducted on sixty patients with clinically diagnosed pregnancy induced hypertension, who were referred to the Department of Radiodiagnosis. In the present study out of sixty pregnancy induced hypertension cases 35 showed positive Doppler indices in any of the three vessels studied. The remaining 25 cases showed normal Doppler indices in all the three vessels studied.

Keywords: uterine artery, doppler ultrasound, pregnancy induced hypertension

Introduction
Pregnancy induced hypertension has been a recognized pathological entity since the time of Hippocrates and ancient Greeks. Hypertensive disorders in pregnancy is one of the major causes of maternal and perinatal mortality and morbidity. It is one of the commonest medical disorders diagnosed by obstetricians in clinical practice. It is said that pregnancy induced hypertension (PIH) contributes to death of a woman every 3 minutes worldwide. Pre-eclampsia is characterized by an imbalance between prostacycline and thromboxane production, as well as failure of the second wave trophoblastic invasion of the endometrio-myometrial vasculature. The result is abnormal uteroplacental blood flow, and this has lead to the idea of using color Doppler in the evaluation and management of PIH patients.

Doppler ultrasound evaluation of the mother and fetus with the study of blood flow indices provides non-invasive assessment to study uteroplacental circulation and fetoplacental circulation and hemodynamic changes and adaptation in the fetal organs in response to hypoxemia; with this, the degree of placental dysfunction can be studied to know the severity of the disease.

Doppler is useful in selecting the patients for induction and trial of labor, also helps in making decisions when to intervene without increasing fetal risk. This in its effect contributes to lowering maternal morbidity and also neonatal morbidity and lowers the incidence of caesarean sections and admission to NICU care, and incidence of prematurity. Among high risk patients, several studies suggested a significant decrease in neonatal morbidity and mortality when Doppler evaluation was a part of fetal surveillance.

Methodology
The study was conducted on sixty patients with clinically diagnosed pregnancy induced hypertension, who were referred to the Department of Radiodiagnosis.

Procedure
The patient was explained about the non-invasive/ atraumatic nature of the procedure. Synthetic ultra gel was applied liberally over the abdomen to get a good acoustic coupling.
The instruments used were Hitachi EUB 5500, Hitachi EUB 7000, Philips Envisor HD C-1.3 Color Doppler ultrasound machine with a convex transducer of 2-5 MHz frequency. Doppler wave form was obtained after localising the vessels by B-mode real time scanner. Pulsed Doppler was used to get the Doppler signals after localising the vessels. The maximum Doppler shift frequencies were obtained and various ratios were calculated from each vessel. Doppler examination was done when fetus was in apneic state to avoid the influence of fetal respiration on Doppler signals.

Identification of various arteries and their criteria

1. Uterine Artery: Colour Doppler facilitates identification of the uterine artery substantially. The uterine signal was obtained per abdomen by pointing the probe in the iliac fossa towards the lower para-cervical area. In the color mode, the uterine artery is seen to cross the external iliac artery, just after its origin from the internal iliac artery and this point was taken as the sampling point. S/D >2.6, RI > 0.58 and persistent early diastolic notch is considered abnormal.

2. Umbilical Artery: Flow velocity waveforms from umbilical artery can be easily obtained, for this color flow is not usually needed. Doppler signals can be acquired from different points in cord, usually from midpoint of cord. S/D ratio of umbilical artery >3, RI>0.7, presence of absent end diastolic velocity (AEDV) and reversed end diastolic velocity (REDV) were considered abnormal.

3. Middle Cerebral Artery (MCA): MCA was visualized in transverse axial view of fetal head at a slightly more caudal plane than the one used for BPD. PI <1.3 and RI <0.7 were considered abnormal.

Results

Table 1: Normal and Abnormal Doppler Wise Distribution of Cases

| Doppler   | Number | Percentage |
|-----------|--------|------------|
| Normal    | 25     | 41.67      |
| Abnormal  | 35     | 58.33      |
| Total     | 60     | 100.00     |

After studying three arteries, patients were classified into normal and abnormal based on their color Doppler indices. Normal were those with no abnormality in any of the arteries.

Table 2: Uterine artery S/D ratio

| Resistance index | No. of cases | Percentage |
|------------------|--------------|------------|
| Abnormal         | 20           | 57.14      |
| Normal           | 15           | 42.86      |
| Total            | 35           | 100.00     |

The table shows more than 50% of cases with elevated S/D ratio.

Table 3: Uterine artery resistance index

| Resistance index | No. of cases | Percentage |
|------------------|--------------|------------|
| Abnormal         | 26           | 74.28      |
| Normal           | 9            | 25.72      |
| Total            | 35           | 100.00     |

The table shows 74% of cases with abnormal RI in this study.

Table 4: Umbilical artery S/D ratio

| Umbilical artery S/D ratio | No. of cases | Percentage |
|--------------------------|--------------|------------|
| Abnormal                 | 30           | 85.71      |
| Normal                   | 5            | 14.29      |
| Total                    | 35           | 100.00     |

Maximum number of cases showed abnormal umbilical artery S/D ratio.

Table 5: Cases with Doppler Abnormality

| Parameters | S/D UA | S/D UT | Notch | AEDV |
|------------|--------|--------|-------|------|
| No.        | %      | No.    | %     | No.  | %    |
| Abnormality present | 30     | 85.71  | 20    | 57.14| 24   | 68.57| 6    | 17.14|
| Abnormality absent   | 5      | 14.29  | 15    | 42.86| 11   | 31.43| 29   | 82.86|
| Total               | 35     | 100.00 | 35    | 100.00| 35   | 100.00| 35   | 100.00|

Comparing to S/D umbilical and S/D uterine χ²=7.00, p<0.01, significant.

Table 6: Middle cerebral artery sensitivity

| Parameters | No. of cases | Percentage |
|------------|--------------|------------|
| No. of cases with abnormal MCA Doppler | 15         | 42.85      |
| No. of cases with normal MCA Doppler  | 20         | 57.15      |
| Total     | 35           | 100.00     |

42% cases show abnormal MCA Doppler findings in the present study.

Table 7: Sensitivity of various vessels studied

| Parameters | No. of cases | Percentage |
|------------|--------------|------------|
| Uterine artery | 24/35       | 68.57      |
| Umbilical artery | 30/35     | 85.71      |
| Fetal MCA      | 15/35       | 42.85      |

The Doppler study of umbilical artery is most sensitive of all the vessels under the study.

In present study, it was found that the cases with bilateral notch were more than those with unilateral notch.

Discussion

In the present study out of sixty pregnancy induced hypertension cases 35 showed positive Doppler indices in any of the three vessels studied. The remaining 25 cases showed normal Doppler indices in all the three vessels studied.

Table 8: Mean Age of Pih Cases

| Parameters | Mean age in Yrs |
|------------|----------------|---------------|
| U.Gupta et al [5] | 23.53          |
| Present Study           | 23.1           |

Present study shows mean maternal age 23.1 yrs which is comparable with other studies and in accordance with normal reproductive age group (18-28) of Indian women.
Table 9: Normal and abnormal Doppler wise distribution of cases

|        | Normal | Abnormal |
|--------|--------|----------|
| Bhatt CJ et al.[6] | 44% | 56% |
| U. Gupta et al.[5] | 45% | 55% |
| Present Study | 41.66% | 58.33% |

As compared with other studies present study also had majority of cases with abnormal Doppler.

Table 10: Cases with Doppler abnormality

| Abnormal Ut.A. S/D | Abnormal UA S/D |
|--------------------|-----------------|
| Trudinger et al.[7] | 47.3% | 40% |
| U. Gupta et al. [5] | 55% | 39% |
| Saxena et al. [8] | 77% | 40% |
| Khalid et al. [9] | 94.44 | 80.56 |
| Present Study | 57.14% | 85.71 |

Present study has shown majority of cases (85.71%) with abnormal umbilical artery S/D ratio, which is comparable to the study conducted by Khalid et al. In other studies majority showed abnormal uterine artery S/D ratio [10].

Conclusion

- Out of 60 cases studied, 35 (58%) showed positive Doppler indices in any of the three vessels studied. The remaining 25 (42%) cases showed normal Doppler indices in all the three vessels studied.
- Among abnormal 35 cases, 30 cases had abnormal S/D ratio, 23 cases had abnormal RI and 6 cases had AEDV in umbilical artery, followed by uterine artery diastolic notch in 24 cases (68.57%), S/D ratio of uterine artery >2.6 in 20 cases (57.14%), RI of >0.58 in 26 cases (74.28%) and abnormal MCA in 15 cases (42.85%).
