ON THE SU(2, 1) REPRESENTATION SPACE OF THE BRIESKORN HOMOLOGY SPHERES

VU THE KHOI

Abstract. In this paper, we give a parameterization of the SU(2, 1) representation space of the Brieskorn homology spheres using the trace coordinates. As applications, we give an example which shows that the orbifold Toledo invariant in [10] does not distinguish the connected components of the PU(2, 1) representation space.

1. Introduction

Let $M$ be a manifold with the fundamental group $\pi_1(M)$ and $G$ be a Lie group. The representation space of $M$, denoted by $R_G(M)$, is the space of representations from $\pi_1(M)$ into the Lie group $G$, modulo conjugation:

$$R_G(M) := \text{hom}(\pi_1(M), G)/G.$$ 

We denote by $R^*_G(M)$ the subset of the representation space which consists of irreducible representations. The representation space of 3-manifolds has been studied extensively in the case where $G = SU(2), SU(3)$ or $SL(2, \mathbb{C})$ in connection with the Casson invariants and hyperbolic geometry (see [2, 3, 5, 6, 7, 9]).

Let us recall that $SU(2, 1)$ is the special unitary group corresponding to the indefinite inner product $\langle Z, W \rangle_{2,1} = Z_1\overline{W}_1 + Z_2\overline{W}_2 - Z_3\overline{W}_3$ on $\mathbb{C}^3$. The group $PU(2, 1)$ is the quotient of $SU(2, 1)$ by its center.

In this paper we study the $SU(2, 1)$ representation space $R_{SU(2,1)}(M)$. The motivation for this study comes from complex hyperbolic geometry where $R_{PU(2,1)}(M)$ serves as the local model for the deformation space of spherical CR structures on $M$.

M. For convenience, we will work with the group \( \text{SU}(2, 1) \) and then deduce results for the \( \text{PU}(2, 1) \) case.

Let \( p, q, r \) be pairwise coprime positive integers, the Brieskorn homology sphere \( \Sigma(p, q, r) \) is defined to be the link of singularity in \( \mathbb{C}^3 \), that is:

\[
\Sigma(p, q, r) := \{ (x, y, z) \mid x^p + y^q + z^r = 0 \} \cap S^5.
\]

It is well known that the fundamental group of \( \Sigma(p, q, r) \) may be given as

\[
\pi_1(\Sigma(p, q, r)) = \langle x, y, h \mid h \text{ central, } x^p h^a = y^q h^b = z^r h^c = xyz = 1 \rangle,
\]

where \( a, b, c \) are integers satisfying

\[
\frac{a}{p} + \frac{b}{q} + \frac{c}{r} = \frac{1}{pqr}.
\]

In this paper, for simplicity, we will denote by \( t_A \) the trace of a matrix \( A \) and \( [A, B] \) the commutator \( ABA^{-1}B^{-1} \). The notations \( \mathfrak{R} \) and \( \mathfrak{I} \) stand for the real and imaginary part of a complex numbers respectively. Our main theorem shows that \( \mathcal{R}_{\text{SU}(2,1)}^*(M) \) can be parameterized by certain trace coordinates.

**Theorem 3.1** Two irreducible representations \( \rho, \rho' : \pi_1(\Sigma(p, q, r)) \rightarrow \text{SU}(2, 1) \) are conjugate if and only if the image under \( \rho \) and \( \rho' \) of each \( x, y, h \) are conjugate and satisfy the relations

\[
t_{\rho(xy)} = t_{\rho'(xy)}, \quad t_{\rho(x^{-1}y)} = t_{\rho'(x^{-1}y)}, \quad \mathfrak{R}(t_{\rho([x,y])}) = \mathfrak{R}(t_{\rho'([x,y])}).
\]

The rest of this paper is organized as follows. In section 2 we study the trace identities for the free group of rank two. Using algebraic results about the invariant ring of matrices, we are able to deduce the coordinates and relations for the \( \text{SU}(2, 1) \) representation space of the free group of rank two. Section 3 is devoted to the proof of the main result. In this section, we also show how to find the constraint for the parameters of the representation spaces in practice. Finally, in section 4, we apply our results to give explicit descriptions of the representation spaces of the Brieskorn homology spheres \( \Sigma(2, 3, 11) \) and \( \Sigma(2, 3, 13) \).
ON THE SU(2,1) REPRESENTATION SPACE OF THE BRIESKORN HOMOLOGY SPHERES 3

2. Trace calculus for free group of rank two

We first recall some known results about matrices in SU(2,1). The reader should consult [4, 8] for details. Let $V_-$ and $V_0$ be the two subsets of $\mathbb{C}^3$ defined by $V_- := \{ Z = (z_1, z_2, z_3) \in \mathbb{C}^3 | \langle Z, Z \rangle_{2,1} < 0 \}$ and $V_0 := \{ Z = (z_1, z_2, z_3) \in \mathbb{C}^3 | \langle Z, Z \rangle_{2,1} = 0 \}$. We denote by $P : \mathbb{C}^3 \setminus \{0\} \to \mathbb{C}P^2$ the canonical projection onto the complex projective space. Then $P(V_-)$ equipped with the Bergman metric is the model of the complex hyperbolic space $H^2_{\mathbb{C}}$. The boundary $\partial H^2_{\mathbb{C}}$ in $\mathbb{C}P^2$ is $P(V_0 \setminus \{0\})$.

The elements of SU(2,1) can be classified according to their action on the complex hyperbolic space $H^2_{\mathbb{C}}$ [4]. Namely, a matrix is called elliptic if it has a fixed point in $H^2_{\mathbb{C}}$. We call it parabolic if it has a unique fixed point in $\overline{H^2_{\mathbb{C}}}$ which lies on $\partial H^2_{\mathbb{C}}$. And finally, an element is called loxodromic if it has exactly two fixed points in $\overline{H^2_{\mathbb{C}}}$ which lie on $\partial H^2_{\mathbb{C}}$.

A classification of conjugacy classes of elements of SU(2,1) can be found in [4]. In particular it says that two elliptic elements are conjugate if and only if they have the same positive and negative class of eigenvalues (counted with multiplicity). An explanation of terminology should be added here: we say that an eigenvalue $\lambda$ of an elliptic element is of positive type (respectively negative type) if it has an $\lambda$-eigenvector $v$ such that $\langle v, v \rangle_{2,1}$ is positive (respectively negative). It has been shown that every eigenvalue of an elliptic element has either positive or negative type.

The next proposition gives several trace identities for a pair of matrices in SU(2,1). These identities will be crucial in getting a coordinate system on the representation space.

**Proposition 2.1.** Let $A$ and $B$ be a pair of matrices in SU(2,1). Then the following equations hold:

i) $t_{A^{-1}} = \overline{t_A}$.

ii) $t_{A^2} = t_A^2 - 2t_A$.

iii) $t_{A^3} = t_A^3 - 3|t_A|^2 + 3$.

iv) $t_{A^2B} = t_A t_{AB} - \overline{t_A t_B} + t_{A^{-1}B}$.

v) $t_{A^2B^2} = t_A t_{AB} - t_A^2 \overline{t_B} + t_A \overline{t_{A^{-1}B}} - \overline{t_A t_B^2} + \overline{t_A t_B} + t_B \overline{t_{A^{-1}B}}$. 
vi) $t_{ABAB^{-1}} = t_{AB}t_{A^{-1}B} + t_{AB}t_B + t_Bt_{A^{-1}B} + t_A(1 - |t_B|^2)$.

vii) $t_{ABA^2B^2} = t_{[A,B]} + t_{AB}t_{A^2B} - t_{AB}t_{AB}$.

Proof. The first identity follows from the definition of SU(2, 1). The next two identities follow from the fact that the characteristic polynomial of $A$ has the form $A^3 - t_A A^2 + t_A A - I$ (see the proof of Theorem 6.2.4 in [8]). Notice that by the Cayley-Hamilton theorem we have $A^3 - t_A A^2 + t_A A - I = 0$. Now by multiplying this equality from the right by $A^{-1}B$ and then taking the trace, we obtain iv).

By multiplying the Cayley-Hamilton identity for $A$ by $A^{-1}B^2$ from the right and using previous identities we get v).

To prove vi) we will combine two equalities. The first one is obtained by multiplying the Cayley-Hamilton identity for $AB$ from the right by $(AB)^{-1}B^{-2}$:

$$ABAB^{-1} - t_{AB}AB^{-1} + t_BB^{-2}B^{-1}AB^{-1}B^{-2}B^{-1}A^{-1}B^{-2} = 0.$$

The second one is obtained by multiplying the Cayley-Hamilton identity for $B$ from the left by $(AB)^{-1}B^{-2}$:

$$B^{-1}A^{-1}B - t_BB^{-1}A^{-1} + t_BB^{-1}A^{-1}B^{-1} - B^{-1}A^{-1}B^{-2} = 0.$$ 

It is not hard to see that when combining these two equalities and simplifying things by the previously proved identities we get the result.

The last identity can be obtained by multiplying the Cayley-Hamilton identity for $AB$ by $(AB)^{-1}B^{-1}AB^2$. □

We now state some algebraic results on the algebra of invariants of matrices. Let $C[M_n^{\otimes m}]$ be the coordinate ring for the space of $m$-tuples of $n \times n$ matrices $(A_k = (a_{ij}^k))_{k=1,\ldots,m}$, i.e., $C[M_n^{\otimes m}] := C[a_{ij}^k]|1 \leq i, j \leq n, 1 \leq k \leq m]$. Consider the action of $GL_n := GL(n, C)$ by simultaneous conjugation of $m$ matrices. Algebraists are interested in the algebra of invariants $C_{n,m} := C[M_n^{\otimes m}]^{GL_n}$.

The following result of Teranishi [13] will be useful for us: The algebra $C_{3,2}$ of invariants of two matrices $X, Y$ in $GL(3, C)$, is generated by:

$$t_X, t_Y, t_X^2, t_XY, t_Y^2, t_X^3, t_X^2Y, t_XY^2, t_Y^3, t_X^2Y^2, t_X^2Y^2XY.$$
ON THE SU(2,1) REPRESENTATION SPACE OF THE BRIESKORN HOMOLOGY SPHERES

This result means that the trace of any word in $X, Y$ can be expressed as a polynomial in the eleven traces above. When working with the group SU(2, 1) we can reduce the number of generators greatly by using Proposition 2.1. We get the following:

**Proposition 2.2.** Let $A$ and $B$ be a pair of matrices in SU(2, 1) then the trace of any word in $A, B$ can be written as a polynomial of the following variables and their complex conjugates:

$\tau_A, \tau_B, \tau_{AB}, \tau_{A^{-1}B}, \tau_{[A,B]}$.

Since the real dimension of SU(2, 1) is 8, the real dimension of the representation space of the free group of rank 2 should also be 8. Therefore there should be a relation among these 5 traces. Fortunately, this relation has been computed in [1, 12] as the defining relation for the algebra of invariants. In particular, it has been shown that the algebra of invariants of two matrices in GL(3, $\mathbb{C}$) is defined by a single relation which expresses $t_{X^2Y^2XY}$ as a solution of a quadratic equation whose coefficients are polynomials in the other ten traces. After plugging our variables into the formula in Theorem 1.2 of [1] and simplifying by MAPLE, we get the following result.

**Proposition 2.3.** Let $A$ and $B$ be two matrices in SU(2, 1). If we denote $\tau_A, \tau_B, \tau_{AB}$ by $a, b, c, d$ respectively, then the following identities hold:

$$\Re(t_{[A,B]}) = \frac{1}{2}(|ab|^2 + |a|^2 + |b|^2 + |c|^2 + |d|^2 - ab\bar{c} - \bar{a}bc - \bar{a}b\bar{d} - \bar{a}b\bar{d} - 3).$$

$$\Im(t_{[A,B]})^2 = \frac{1}{4}(|ab|^2 - |a|^2 - |b|^2 + |c|^2 + |d|^2 - ab\bar{c} - \bar{a}bc - \bar{a}b\bar{d} - \bar{a}b\bar{d})^2$$

$$+ 2\Re(-a^3|b|^2 + a^2b^2d + a^2b^2c - a|b|^2dc - |a|^2b^3 - |a|^2bcd + a^2\bar{c}d + a^2\bar{c}d + a^2\bar{d}^2 - 2abc^2 + acc^2 + bd\bar{c}^2 + b^2c\bar{a} - 2bd^2\bar{a} + c^2d\bar{a} + a^3 + \frac{3}{2}ab\bar{c} + \frac{3}{2}a\bar{b}d - 3ac\bar{d} + b^3 + b^2\bar{c}d - 3bcd + c^3 + d^3 + d^3 + d^3)$$

$$+ \frac{5}{2}ab|^2 + |cd|^2 - \frac{9}{2}(|a|^2 + |b|^2 + |c|^2 + |d|^2) + \frac{27}{4}.$$  

3. **Parameterization of the representation space**

In this section we will show that the traces of certain elements give a coordinate system for the irreducible part of the representation space of the Brieskorn homology
sphere. Furthermore we also show how to determine the constraint region for the coordinates.

**Theorem 3.1.** Two irreducible representations \( \rho, \rho' : \pi_1(\Sigma(p, q, r)) \rightarrow \text{SU}(2, 1) \) are conjugate if and only if the image under \( \rho \) and \( \rho' \) of each \( x, y, h \) are conjugate and satisfy the relations

\[
\begin{align*}
& t_\rho(xy) = t_\rho'(xy), \quad t_\rho(x^{-1}y) = t_\rho'(x^{-1}y), \quad \Im(t_\rho([x,y])) = \Im(t_\rho'([x,y])).
\end{align*}
\]

**Proof.** If \( \rho \) and \( \rho' \) are conjugate, then the required relations are obviously satisfied. On the contrary suppose the relations hold. Since \( \rho \) and \( \rho' \) are irreducible, \( \rho(h) \) and \( \rho'(h) \) should be in the center \( Z(\text{SU}(2, 1)) \) of \( \text{SU}(2, 1) \). Notice that the images of \( x, y, z \) under a representation are elliptic elements, and they are diagonalizable. Moreover, it also follows from the irreducibility that either \( \rho(x) \) or \( \rho(y) \) has three distinct eigenvalues since otherwise \( \rho \) would have a non-trivial invariant subspace by dimensional reason. The same holds for \( \rho' \). So, after conjugation, we may assume that \( \rho(x) = \rho'(x) = \text{diag}(e^{i\theta_1}, e^{i\theta_2}, e^{i\theta_3}) \), where \( e^{i\theta_1}, e^{i\theta_2}, e^{i\theta_3} \) are distinct numbers and \( \text{diag}(a, b, c) \) denotes the diagonal matrix whose diagonal elements are \( a, b, c \).

To prove the theorem, it is enough to show that we can conjugate \( \rho(y) \) to \( \rho'(y) \) by a diagonal matrix. To show this we prepare a small lemma.

**Lemma 3.2.** Let \( A = \text{diag}(e^{i\theta_1}, e^{i\theta_2}, e^{i\theta_3}) \), where \( e^{i\theta_1}, e^{i\theta_2}, e^{i\theta_3} \) are three distinct numbers. Suppose that \( B = (b_{ij}) \) and \( B' = (b'_{ij}) \) are two \( 3 \times 3 \) matrices satisfying \( t_B = t_{B'} \), \( t_{AB} = t_{AB'} \), \( t_{A^{-1}B} = t_{A^{-1}B'} \). Then the diagonal elements of \( B \) and \( B' \) are equal.

**Proof.** It follows from our assumption that the following equations hold:

\[
\begin{align*}
& (b_{11} - b'_{11}) + (b_{22} - b'_{22}) + (b_{33} - b'_{33}) = 0 \\
& (b_{11} - b'_{11})e^{i\theta_1} + (b_{22} - b'_{22})e^{i\theta_2} + (b_{33} - b'_{33})e^{i\theta_3} = 0 \\
& (b_{11} - b'_{11})e^{-i\theta_1} + (b_{22} - b'_{22})e^{-i\theta_2} + (b_{33} - b'_{33})e^{-i\theta_3} = 0
\end{align*}
\]
Consider this as a system of linear equations in \(b_{ii} - b'_{ii}\). Since the determinant
\[
\begin{vmatrix}
1 & 1 & 1 \\
e^{i\theta_1} & e^{i\theta_2} & e^{i\theta_3} \\
e^{-i\theta_1} & e^{-i\theta_2} & e^{-i\theta_3}
\end{vmatrix}
\]
is not zero, we get the conclusion of the lemma.

Now come back to the proof of our theorem, suppose that \(\rho(y) = (y_{ij})\) and \(\rho'(y) = (y'_{ij})\). From our assumption and Proposition 2.3, we have \(t_{\rho(w)} = t_{\rho'(w)}\) for every word \(w(x,y)\). Applying Lemma 3.2 for \(A = \rho(x), B = \rho(y)\) and \(B' = \rho'(y)\), we obtain
\[
(*) \quad y_{i,i} = y'_{i,i} \quad (i = 1, 2, 3).
\]
Applying Lemma 3.2 again for \(A = \rho(x), B = \rho([x, y])\) and \(B' = \rho'([x, y])\), we conclude that the corresponding diagonal elements of \(\rho([x, y])\) and \(\rho'([x, y])\) are equal. For the first diagonal element, we have:
\[
|y_{11}|^2 + |y_{12}|^2 e^{i(\theta_1 - \theta_2)} - |y_{13}|^2 e^{i(\theta_1 - \theta_3)} = |y'_{11}|^2 + |y'_{12}|^2 e^{i(\theta_1 - \theta_2)} - |y'_{13}|^2 e^{i(\theta_1 - \theta_3)}.
\]
Using the fact that \(\rho(x), \rho(y)\) belong to \(\text{SU}(2,1)\) and \(y_{11} = y'_{11}\), we get the following equations:
\[
\begin{cases}
(\|y_{12}\|^2 - |y'_{12}|^2) & -(\|y_{13}\|^2 - |y'_{13}|^2) = 0 \\
(\|y_{12}\|^2 - |y'_{12}|^2) e^{i(\theta_1 - \theta_2)} & -(\|y_{13}\|^2 - |y'_{13}|^2) e^{i(\theta_1 - \theta_3)} = 0.
\end{cases}
\]
From these equations, it follows that \(|y_{12}| = |y'_{12}|\) and \(|y_{13}| = |y'_{13}|\). Arguing similarly for other diagonal elements of \(\rho([x, y])\) and \(\rho'([x, y])\), we obtain that
\[
(**) \quad |y_{ij}| = |y'_{ij}| \quad (i \neq j).
\]
Applying Lemma 3.2 one more time for \(A = \rho(x), B = \rho(y^2)\) and \(B' = \rho'(y^2)\), it follows that the corresponding diagonal elements of \(\rho(y^2)\) and \(\rho'(y^2)\) are equal. Combining with \((*)\), we obtain the following equalities:
\[
(* *) \quad y_{ij}y_{ji} = y'_{ij}y'_{ji} \quad (i \neq j).
\]
Now consider three pairs \((y_{ij}, y'_{ji})\) for \(i < j\). By the irreducibility of \(\rho\), at least two pairs are not equal to \((0, 0)\). Without loss of generality, we may assume that, say,
$y_{12} \neq 0$ and $y_{31} \neq 0$. By conjugate $\rho$ by $\text{diag}(e^{i\phi_1}, e^{i\phi_2}, e^{i\phi_3})$ for appropriate values of $\phi_1$ and using (**), we may assume that $y_{12} = y'_{12}$ and $y_{31} = y'_{31}$. Furthermore, using (**), we get that $y_{21} = y'_{21}$ and $y_{13} = y'_{13}$. Moreover, since $\rho(y)$ and $\rho'(y)$ are in $\text{SU}(2_1)$, we obtain

$$y_{11}y_{12} + y_{21}y_{22} - y_{31}y_{32} = 0, \quad y'_{11}y'_{12} + y'_{21}y'_{22} - y'_{31}y'_{32} = 0.$$ 

It follows that $y_{32} = y'_{32}$. By a similar argument, we also get $y_{23} = y'_{23}$ and thus our theorem is proved. \hfill \blackslug

To describe the representation space, for each $h \in \mathbb{Z}(\text{SU}(2_1))$, $x = \text{diag}(\lambda_1, \lambda_2, \lambda_3)$, $y = P\text{diag}(\mu_1, \mu_2, \mu_3)P^{-1}$, $P \in \text{SU}(2_1)$ such that $x^ph^a = y^qh^b = I$, we need to answer the following two questions:

- Does there exist $P$ such that $z = (xy)^{-1}$ satisfies $z^rh^c = I$?
- What are the possible values of $t_{x^{-1}y}$?

In other words, we need to find the image of the following map in terms of $\lambda = (\lambda_1, \lambda_2, \lambda_3)$ and $\mu = (\mu_1, \mu_2, \mu_3)$:

$$\Phi_{\lambda, \mu} : \text{SU}(2_1) \longrightarrow \mathbb{C}^2$$

$$P \quad \mapsto \quad (t_{xy}, t_{x^{-1}y}),$$

where $x = \text{diag}(\lambda_1, \lambda_2, \lambda_3)$ and $y = P\text{diag}(\mu_1, \mu_2, \mu_3)P^{-1}$.

If we write $P = (p_{ij})$, then we have

$$P^{-1} = \begin{pmatrix}
    \bar{p}_{11} & \bar{p}_{21} & -\bar{p}_{31} \\
    \bar{p}_{12} & \bar{p}_{22} & -\bar{p}_{32} \\
    -\bar{p}_{13} & -\bar{p}_{23} & \bar{p}_{33}
\end{pmatrix}.$$ 

Let us denote by $\hat{P}$ for the matrix

$$\hat{P} = \begin{pmatrix}
    |p_{11}|^2 & |p_{12}|^2 & -|p_{13}|^2 \\
    |p_{21}|^2 & |p_{22}|^2 & -|p_{23}|^2 \\
    -|p_{31}|^2 & -|p_{32}|^2 & |p_{33}|^2
\end{pmatrix}.$$ 

Then we have

$$t_{xy} = (\lambda_1, \lambda_2, \lambda_3) \hat{P} (\mu_1, \mu_2, \mu_3)^T, \quad t_{x^{-1}y} = \left(\frac{1}{\lambda_1}, \frac{1}{\lambda_2}, \frac{1}{\lambda_3}\right) \hat{P} (\mu_1, \mu_2, \mu_3)^T.$$
Let $\mathcal{D}$ be the set of $3 \times 3$ matrices $M$ such that there exists $P = (p_{ij}) \in \text{SU}(2, 1)$ satisfying $M = \hat{P}$. An explicit description of $\mathcal{D}$ in the following lemma will help us to find the image of $\Phi_{\lambda, \mu}$ in practice.

**Lemma 3.3.** Let $M$ be the matrix

$$M = \begin{pmatrix} m_{11} & m_{12} & -m_{13} \\ m_{21} & m_{22} & -m_{23} \\ -m_{31} & -m_{32} & m_{33} \end{pmatrix}$$

such that $m_{ij} \geq 0$ and the sum of every row or column is 1. Then $M$ is an element of $\mathcal{D}$ if and only if the following triangle inequalities holds:

$$\sqrt{m_{1k}m_{2k}} \leq \sum_{i \neq k} \sqrt{m_{1i}m_{2i}} \quad (k = 1, 2, 3).$$

**Proof.** We first show the if part: If $M \in \mathcal{D}$ then there exist $\theta_{ij}$ such that the matrix $(\sqrt{m_{ij}}e^{i\theta_{ij}})$ belongs to $\text{SU}(2, 1)$, and hence we have

$$\sqrt{m_{11}m_{21}}e^{i(\theta_{11} - \theta_{21})} + \sqrt{m_{12}m_{22}}e^{i(\theta_{12} - \theta_{22})} - \sqrt{m_{13}m_{23}}e^{i(\theta_{13} - \theta_{23})} = 0.$$

It implies that the three numbers $\sqrt{m_{1i}m_{2i}}$ $(i = 1, 2, 3)$ must satisfy the triangle inequalities and the lemma follows.

We next show the “only if” part: Now suppose that three numbers $\sqrt{m_{1i}m_{2i}}$ $(i = 1, 2, 3)$ satisfy the triangle inequalities. Then there exist angles $\theta_{ij}$ satisfying

$$\sqrt{m_{11}m_{21}}e^{i(\theta_{11} - \theta_{21})} + \sqrt{m_{12}m_{22}}e^{i(\theta_{12} - \theta_{22})} - \sqrt{m_{13}m_{23}}e^{i(\theta_{13} - \theta_{23})} = 0.$$

Put $p_{ij} = \sqrt{m_{ij}}e^{i\theta_{ij}}$ $(i = 1, 2, j = 1, 2, 3)$, then we get the first two rows of the matrix $P$. Let $v = (p_{31}, p_{32}, p_{33})$ be the vector which is orthogonal to these two rows with respect to the indefinite inner product $\langle , \rangle_{2,1}$, and also satisfies $\langle v, v \rangle_{2,1} = -1$. Then it is not hard to check $P = (p_{ij}) \in \text{SU}(2, 1)$ and $M = \hat{P}$.

\[ \square \]

## 4. EXAMPLES

**Example 1.** The first example is the manifold $\Sigma(2, 3, 11)$. Its fundamental group has the following presentation.

$$\pi_1(\Sigma(2, 3, 11)) = \langle x, y, z, h \mid h \text{ central}, x^2h^{-1} = y^3h = z^{11}h^2 = xyz = 1 \rangle.$$
In this example the irreducible representation space consists of isolated points.

For each $h = \text{diag}(e, e, e)$, with $e^3 = 1$, we look for $\lambda$ and $\mu$ satisfying

$$\lambda_i^2 = e, \quad \mu_i^3 = e^{-1} \quad (i = 1, 2, 3), \quad \lambda_1 \lambda_2 \lambda_3 = 1, \quad \mu_1 \mu_2 \mu_3 = 1$$

such that the image of $\Phi_{\lambda, \mu}$ contains a point whose first coordinate is of the form $e^{i\theta_1} + e^{i\theta_2} + e^{i\theta_3}$ with $\theta_1 + \theta_2 + \theta_3 = 2k\pi$ and $e^{11i\theta} = e^2$ for all $i$.

A small computer search tells us that there are five irreducible representations into $SU(2,1)$, all corresponding to the case $\rho(h) = I$. The parameters of these representations are given below. Here we use $\sim$ to denote the conjugacy relation.

1) $\rho(x) \sim \text{diag}(1, -1, -1), \quad \rho(y) \sim \text{diag}(1, e^{4\pi i/3}, e^{2\pi i/3}),$

$$t_{\rho(xy)} = t_{\rho(x^{-1}y)} = e^{10\pi i/11} + e^{16\pi i/11} + e^{18\pi i/11}, \quad \Im(t_{\rho([x,y])}) = 0.$$

2) $\rho(x) \sim \text{diag}(1, -1, -1), \quad \rho(y) \sim \text{diag}(e^{2\pi i/3}, 1, e^{4\pi i/3}),$

$$t_{\rho(xy)} = t_{\rho(x^{-1}y)} = e^{4\pi i/11} + e^{6\pi i/11} + e^{12\pi i/11}, \quad \Im(t_{\rho([x,y])}) = 0.$$

3) $\rho(x) \sim \text{diag}(-1, -1, 1), \quad \rho(y) \sim \text{diag}(1, e^{4\pi i/3}, e^{2\pi i/3}),$

$$t_{\rho(xy)} = t_{\rho(x^{-1}y)} = e^{4\pi i/11} + e^{8\pi i/11} + e^{10\pi i/11}, \quad \Im(t_{\rho([x,y])}) = 0.$$

4) $\rho(x) \sim \text{diag}(-1, 1, -1), \quad \rho(y) \sim \text{diag}(e^{2\pi i/3}, 1, e^{4\pi i/3}),$

$$t_{\rho(xy)} = t_{\rho(x^{-1}y)} = e^{12\pi i/11} + e^{14\pi i/11} + e^{18\pi i/11}, \quad \Im(t_{\rho([x,y])}) = 0.$$

5) $\rho(x) \sim \text{diag}(-1, 1, -1), \quad \rho(y) \sim \text{diag}(e^{2\pi i/3}, e^{4\pi i/3}, 1),$

$$t_{\rho(xy)} = t_{\rho(x^{-1}y)} = 1 + 2\cos(2\pi/11), \quad \Im(t_{\rho([x,y])}) = 0.$$

It is no surprise that $t_{\rho(xy)} = t_{\rho(x^{-1}y)}$ and $\Im(t_{\rho([x,y])}) = 0$ in all the cases since $\rho(x)^2 = I$. We can easily check that these representations give 5 distinct irreducible representations when considered as elements of $\mathcal{R}_{PU(2,1)}^*(\Sigma(2,3,11))$.

The Toledo invariant for representations of the fundamental group of an oriented surface into $PU(\rho, 1)$ is defined in [14]. In [10 11], M. Krebs defines the Toledo invariant for orbifold fundamental groups and uses it to obtain a lower bound for the number of connected components of the $PU(2,1)$ representation space. In particular, it is shown in [14] that $\mathcal{R}_{PU(2,1)}^*(\Sigma(2,3,11))$ has at least 5 connected components. So in this case the bound obtained by using the Toledo invariant is sharp.

**Example 2.** Our next example is the manifold $\Sigma(2,3,13)$ which has the fundamental group:

$$\pi_1(\Sigma(2,3,13)) = \langle x, y, z, h \mid h \text{ central}, \quad x^2 h = y^3 h^{-1} = z^{13} h^{-2} = xyz = 1 \rangle.$$
A similar computer search as in the previous example shows that the irreducible representation space $\mathcal{R}_{SU(2,1)}^*(\Sigma(2, 3, 13))$ consists of 8 isolated points. In the following, we list the parameters of these representations. Note that $\rho(h) = I$ in all the cases.

1) $\rho(x) \sim \text{diag}(-1, 1, -1), \quad \rho(y) \sim \text{diag}(e^{2\pi i/3}, e^{4\pi i/3}, 1), \quad t_{\rho(xy)} = t_{\rho(x^{-1}y)} = e^{4\pi i/13} + e^{10\pi i/13} + e^{12\pi i/13}, \quad \Im(t_{\rho([x,y])}) = 0.$

2) $\rho(x) \sim \text{diag}(-1, 1, -1), \quad \rho(y) \sim \text{diag}(e^{2\pi i/3}, e^{4\pi i/3}, 1), \quad t_{\rho(xy)} = t_{\rho(x^{-1}y)} = e^{14\pi i/13} + e^{16\pi i/13} + e^{22\pi i/13}, \quad \Im(t_{\rho([x,y])}) = 0.$

3) $\rho(x) \sim \text{diag}(-1, 1, -1), \quad \rho(y) \sim \text{diag}(1, e^{4\pi i/3}, e^{2\pi i/3}), \quad t_{\rho(xy)} = t_{\rho(x^{-1}y)} = e^{6\pi i/13} + e^{22\pi i/13} + e^{24\pi i/13}, \quad \Im(t_{\rho([x,y])}) = 0.$

4) $\rho(x) \sim \text{diag}(-1, 1, -1), \quad \rho(y) \sim \text{diag}(1, e^{2\pi i/3}, e^{4\pi i/3}), \quad t_{\rho(xy)} = t_{\rho(x^{-1}y)} = e^{2\pi i/13} + e^{4\pi i/13} + e^{20\pi i/13}, \quad \Im(t_{\rho([x,y])}) = 0.$

5) $\rho(x) \sim \text{diag}(-1, 1, -1), \quad \rho(y) \sim \text{diag}(1, e^{4\pi i/3}, e^{2\pi i/3}), \quad t_{\rho(xy)} = t_{\rho(x^{-1}y)} = e^{6\pi i/13} + e^{8\pi i/13} + e^{12\pi i/13}, \quad \Im(t_{\rho([x,y])}) = 0.$

6) $\rho(x) \sim \text{diag}(-1, 1, -1), \quad \rho(y) \sim \text{diag}(e^{2\pi i/3}, e^{4\pi i/3}, 1), \quad t_{\rho(xy)} = t_{\rho(x^{-1}y)} = 1 + 2\cos(2\pi/13), \quad \Im(t_{\rho([x,y])}) = 0.$

7) $\rho(x) \sim \text{diag}(-1, -1, 1), \quad \rho(y) \sim \text{diag}(e^{2\pi i/3}, e^{4\pi i/3}, 1), \quad t_{\rho(xy)} = t_{\rho(x^{-1}y)} = 1 + 2\cos(4\pi/13), \quad \Im(t_{\rho([x,y])}) = 0.$

8) $\rho(x) \sim \text{diag}(-1, 1, -1), \quad \rho(y) \sim \text{diag}(1, e^{2\pi i/3}, e^{4\pi i/3}), \quad t_{\rho(xy)} = t_{\rho(x^{-1}y)} = e^{14\pi i/13} + e^{18\pi i/13} + e^{20\pi i/13}, \quad \Im(t_{\rho([x,y])}) = 0.$

These representations give us 8 distinct points of $\mathcal{R}_{PU(2,1)}^*(\Sigma(2, 3, 13))$. According to \[\text{(Appendix)}, in this case there are 7 distinct values of the orbifold Toledo invariant. So the orbifold Toledo invariant does not distinguish the connected components of $\mathcal{R}_{PU(2,1)}^*(\Sigma(2, 3, 13)).$

**Acknowledgment.** The author would like to thank Professor Takashi Tsuboi for advice and hospitality during the time in Tokyo. The author is grateful to his former thesis advisor, Daniel Ruberman, for informing him of the work of M. Krebs and for continuous support. We express our sincere thanks to the anonymous referee for pointing out several inaccuracies in the earlier version of this paper.
