B.1.351 is the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) variant most resistant to antibody neutralization. We demonstrate how the dose and number of immunizations influence protection. Nonhuman primates received two doses of 30 or 100 µg of Moderna’s mRNA-1273 vaccine, a single immunization of 30 µg, or no vaccine. Two doses of 100 µg of mRNA-1273 induced 50% inhibitory reciprocal serum dilution neutralizing antibody titers against live SARS-CoV-2 p.Asp614Gly and B.1.351 of 3,300 and 240, respectively. Higher neutralizing responses against B.1.617.2 were also observed after two doses compared to a single dose. After challenge with B.1.351, there was ~4- to 5-log10 reduction of viral subgenomic RNA and low to undetectable replication in bronchoalveolar lavages in the two-dose vaccine groups, with a 1-log10 reduction in nasal swabs in the 100-µg group. These data establish that a two-dose regimen of mRNA-1273 will be critical for providing upper and lower airway protection against major variants of concern.

The emergence of SARS-CoV-2 variants of concern (VOCs) that show reduced neutralization by convalescent or vaccine-induced immune serum from the Wuhan-1 strain has created uncertainty about the efficacy of current SARS-CoV-2 vaccines against VOC infection. So far, the most concerning variants contain combinations of mutations and deletions in the spike (S) protein receptor-binding domain (RBD) and N-terminal domain (NTD). Acquisition of amino acid substitutions in the S RBD, namely p.Lys417Asn, p.Glu484Lys and p.Asn501Tyr, and in the NTD, such as p.Leu18Phe, p.Asp80Ala, p.Asp215Gly and Δ242–244, is associated with increased transmissibility and reduction in neutralization sensitivity. Variants containing these substitutions, originally isolated in the United Kingdom (UK; B.1.1.7, Alpha), Republic of South Africa (B.1.351, Beta), Brazil (P1 lineage, Gamma), New York (B.1.526) and California (B.1.427/B.1.429), have shown varying reductions in neutralization by convalescent and vaccine sera and are resistant to some monoclonal antibodies. Moreover, the B.1.617.2 (Delta) variant is now the most prevalent variant circulating globally and shows some resistance to neutralization by sera from vaccinated individuals.

Among these variants, B.1.351 contains the most mutations in the RBD and NTD subdomains and has been shown to have the largest fold reduction in neutralizability by potent RBD-specific monoclonal antibodies, including LY-CoV555 (ref. 19), and convalescent serum from individuals infected with ancestral SARS-CoV-2 strains. Additionally, it was reported that sera from mRNA-1273-immunized human and nonhuman primates (NHPs) showed the greatest reduction of neutralization against B.1.351 compared to B.1.1.7, P1, B.1.427/B.1.429 and B.1.1.7 + Glu484Lys variants. In UK-based or US-based clinical studies, NVX-CoV2373 (Novavax), AZD1222 (University of Oxford/AstraZeneca) and Ad26.COV2.S (Janssen/Johnson & Johnson)
vaccines show between ~70 and 90% protection against the circulating p.Asp614Gly or B.1.1.7 variants,[25–29], and vaccine efficacy against mild symptomatic coronavirus disease 2019 (COVID-19) caused by B.1.351 was up to 60% for Ad26.CoV2 (ref. 29) and NVX-CoV2373 (ref. 28) and ~10% for AZD122 (refs. 27–29). A recent report showed that BNT162b2, Pfizer’s mRNA vaccine, conferred ~75% protection against SARS-CoV-2 in NHPs challenged with B.1.351 variant, we evaluated the impact of the dose and no published studies on vaccine protection in NHPs challenged with the B.1.351 variant, we evaluated the impact of the dose and number of immunizations with mRNA-1273 on immunogenicity and protection against B.1.351 challenge in NHPs. Here, we show a correlation between high mRNA-1273-induced antibody responses and decreased viral replication following B.1.351 challenge to establish that a two-dose regimen of mRNA-1273 will be critical for providing upper and lower airway protection against major VOCs. Vaccine development for COVID-19 has benefited from clinically translatable data from the NHP model[33–39]. As there have been no published studies on vaccine protection in NHPs challenged with the B.1.351 variant, we evaluated the impact of the dose and number of immunizations with mRNA-1273 on immunogenicity and protection against B.1.351 challenge in NHPs. Here, we show a correlation between high mRNA-1273-induced antibody responses and decreased viral replication following B.1.351 challenge to establish that a two-dose regimen of mRNA-1273 will be critical for providing upper and lower airway protection against major VOCs.

Results

Antibody responses following mRNA-1273 vaccination. In previous studies, vaccination of NHPs with 10–100 µg of mRNA-1273 at weeks 0 and 4 conferred rapid and complete control of detectable viral replication in both the upper and lower airways following SARS-CoV-2 USA/Washington-1 (WA-1) challenge.[30–32]. In the current study, to assess the influence of dose and number of immunizations on immunogenicity and protection against B.1.351, NHPs were immunized with 30 or 100 µg in the standard 0-week and 4-week vaccine regimen (x2) or a single dose (x1) of 30 µg (Extended Data Fig. 1).

We first performed a temporal analysis of serum neutralizing antibody responses after single immunization or prime and boost with mRNA-1273. Consistent with a previous study,[33] there was a ~100-fold increase in p.Asp614Gly-specific lentiviral pseudovirus neutralizing antibodies following a boost with 30 or 100 µg of mRNA-1273 (Extended Data Fig. 2a). All 8 of the 100 µg × 2 immunized NHPs and 7 of 8 receiving 30 µg × 2 had >10⁶ reciprocal 50% inhibitory dose (ID₅₀) titers 7–8 weeks after boost, and 13 of 16 animals from both two-dose regimens had detectable neutralizing activity against B.1.351 (Extended Data Fig. 2b). By contrast, only 6 of 8 NHPs that received a single dose of 30 µg had detectable neutralizing responses against p.Asp614Gly at that same time point, and none (0/8) had detectable neutralizing antibodies against B.1.351 (Extended Data Fig. 2a,b).

Focusing immune analysis at the time of SARS-CoV-2 B.1.351 challenge, ~8 weeks after boost or 12 weeks after the single immunization, S-specific binding and neutralizing antibody responses were assessed. Using a 10-plex MULTI-ARRAY ELISA, we assessed WA-1 (Fig. 1a,e) and B.1.351 (Fig. 1d,h) S-specific and RBD-specific antibody binding responses, which represent the vaccine and challenge strains, respectively. B.1.351 S-specific (Fig. 1a,d) and RBD-specific (Fig. 1e,h) antibody responses were reduced by less than twofold to threefold for each vaccine group as compared to WA-1 S. There was a vaccine dose-dependent increase in S-specific and RBD-specific antibody responses against WA-1 (Fig. 1a,e), B.1.351 (Fig. 1d,h), B.1.1.7 (Fig. 1b,f) and P.1 (Fig. 1c,g).

In vitro neutralizing activity was next determined using two pseudovirus neutralization assays and a live-virus assay. Neutralizing titers against B.1.351 were compared to p.Asp614Gly, the benchmark strain. Using a p.Asp614Gly lentiviral-based pseudovirus neutralization assay, the reciprocal ID₅₀ geometric mean titer (GMT) was ~3,600 following two doses of 100 µg (Fig. 1i and Extended Data Fig. 2a). Consistent with the eightfold reduction reported by us and others using human vaccine or convalescent serum,[25,28,29], the reciprocal ID₅₀ GMT against B.1.351 was ~450 (Fig. 1i and Extended Data Fig. 2b). Notably, in NHPs that received a single 30-µg dose of mRNA, the reciprocal ID₅₀ GMT against p.Asp614Gly was ~130, but there were no detectable neutralizing antibodies against B.1.351 (Fig. 1i). We observed similar outcomes comparing D614G to B.1.351 using vesicular stomatitis virus (VSV)-based pseudovirus (Fig. 1j) and live-virus (Fig. 1k) neutralization assays. To extend the analysis, there was little change in neutralization in any vaccine group comparing p.Asp614Gly to B.1.1.7 (Fig. 1j) but the reduction in neutralization against the P.1 variant (Fig. 1m) was similar to that observed with B.1.351 (Fig. 1i). Last, there was an average threefold reduction in GMT (half-maximal effective concentration (EC₅₀)) in serum neutralizing activity against B.1.617.2 compared to p.Asp614Gly in animals that received two doses of 30 or 100 µg of mRNA-1273 and undetectable responses in the 30-µg single-dose group. Nevertheless, reciprocal ID₅₀ neutralizing responses were ~400 and ~750 in the 30-µg and 100-µg two-dose groups, respectively. Antibody binding and neutralization responses were highly correlated with one another (Extended Data Fig. 3).

To extend the antibody analyses to the mucosal sites of infection, S-specific and RBD-specific IgG and IgA in bronchoalveolar lavage (BAL) and nasal wash samples were assessed at ~3 weeks after boost or 7 weeks after the single 30-µg immunization. Consistent with systemic humoral responses, there was a dose-dependent increase in BAL and nasal wash WA-1 or B.1.351 S-specific IgG and IgA (Fig. 2a–h), BAL WA-1 (Fig. 2a) or B.1.351 (Fig. 2b), S-specific IgA responses in nasal wash samples trended higher only in the two-dose vaccine groups compared to control NHPs (Fig. 2g,h). RBD-specific antibody responses followed similar trends to S-specific responses (Fig. 2i–p). Overall, mRNA-1273 vaccination elicits WA-1 and B.1.351 S-specific IgG and IgA antibodies in serum and lower and upper airways, as previously shown.[34]

T cell responses following mRNA-1273 vaccination. mRNA-1273 induces type 1 helper T (T₄₁) cells, CD4⁺ follicular helper T (T₉₁) and CD8⁺ T cells in NHPs and humans.[33,41,42]. Consistent with these data, S-specific T₄₁ responses were induced in a dose-dependent manner with higher responses in the 100-µg group (Fig. 3a). There were low to undetectable type 2 helper T (T₉₂) cell responses in all vaccine groups (Fig. 3b).

---

Fig. 1 | Serum antibody responses following mRNA-1273 immunization. a–n. Twenty-four rhesus macaques were immunized with mRNA-1273 (30 µg, one dose (light blue) or two doses (dark blue); or 100 µg, two doses (red)), according to Extended Data Fig. 1. Eight aged-matched naive NHPs (gray) were used as controls. Sera collected at week 12, immediately before challenge, were assessed for SARS-CoV-2 USA/WA-1 (a and e), B.1.1.7 (b and f), P.1 (c and g) and B.1.351 (d and h) S-specific (a–d) and RBD-specific (e–h) IgG by MULTI-ARRAY ELISA. Lentiviral-based pseudovirus neutralization (i and n) was conducted on SARS-CoV-2 p.Asp614Gly and B.1.351 (i), B.1.1.7 (I), P.1 (m) and B.1.617.2 (n). p.Asp614Gly and B.1.351 VSV-based pseudovirus neutralization (j) and focus-reduction live-virus neutralization (k) were also assessed. Data represent one independent experiment. a–h, Circles represent individual NHPs. Boxes and horizontal bars denote the interquartile range (IQR) and medians, respectively; whisker end points are equal to the maximum and minimum values. i–n, Gray lines represent individual NHPs, and colored lines represent GMTs. Dotted lines indicate neutralization assay limits of detection. Symbols represent individual NHPs and may overlap for equal values. Data represent one independent experiment. AUC, area under the curve.
also dose dependence in the frequency of S-specific T<sub>H</sub> responses expressing the surface marker CD40L (Fig. 3c) or the canonical cytokine interleukin (IL)-21 (Fig. 3d), which are critical for improving antibody responses. S-specific CD8<sup>+</sup> T cell responses were observed in five of eight NHPs that received two doses of 100µg mRNA-1273 (Fig. 3e). These data show that mRNA-1273 induces T<sub>H</sub>1-skewed and T<sub>FH</sub>-skewed CD4 responses and CD8<sup>+</sup> T cells at the highest dose.

Protection against SARS-CoV-2 replication in the airways. An extensive analysis was performed to characterize the nucleotide sequence and in vivo pathogenicity. Deep sequencing was
Fig. 2 | Mucosal antibody responses following mRNA-1273 immunization. a–p, Twenty-four rhesus macaques were immunized according to Extended Data Fig. 1, and compared to eight age-matched controls. BAL (a, b, e, f, i, j, m and n) and nasal washes (c, d, g, h, k, l, o and p) collected at week 7 were assessed for SARS-CoV-2 WA-1 (a, c, e, g, i, k, m and o) and B.1.351 (b, d, f, h, j, l, n and p) S-specific (a–h) and RBD-specific (i–p) IgG (a–d and i–l) and IgA (e–h and m–p) by MULTI-ARRAY ELISA. performed after each passage (P) of the B.1.351 strain, and the challenge stock retained all mutations in the RBD and NTD sites on the spike protein (Extended Data Fig. 4a). The John Hopkins University (JHU) B.1.351 P2 stock was then administered to golden Syrian hamsters, a highly pathogenic SARS-CoV-2 animal model, at three different concentrations to characterize weight loss (Extended Data Fig. 4b) and in NHPs to measure upper and lower airway viral replication by quantitative PCR with reverse transcription (RT–qPCR) for subgenomic RNA (sgRNA; Extended Data Fig. 4c,d). Based on these data, a B.1.351 challenge dose of $5 \times 10^5$ plaque-forming units (PFUs) was selected for the vaccine study; this dose would induce sgRNA levels similar to the higher values obtained from nasal secretions of humans following SARS-CoV-2 infection $^{43,44}$.

To assess the protective efficacy of mRNA-1273 against the B.1.351 SARS-CoV-2 variant, the NHPs were challenged with a total dose of $5 \times 10^5$ PFUs of B.1.351 by intratracheal and intranasal routes 7–8 weeks after boost for the two-dose regimens and 12 weeks after the single-dose regimen. Two days after challenge, only two of eight NHPs that received 100 $\mu$g $\times$ 2 of mRNA-1273 had detectable SARS-CoV-2 envelope (E) sgRNA (sgRNA_E) in BAL compared to all NHPs in the control group (Fig. 4a). By RT–qPCR of sgRNA_E in BAL (Fig. 4a) or nucleocapsid (N) sgRNA (sgRNA_N) in BAL (Fig. 4c), the 100-$\mu$g $\times$ 2 group had a significant decrease in viral load compared to NHPs that received a single dose of 30 $\mu$g ($P=0.0054$) or to the control NHPs ($P=0.0009$). NHPs that received 30 $\mu$g $\times$ 2 also had a significant decrease in viral load compared to control NHPs ($P=0.0054$) and showed a trend toward

NATURE IMMUNOLOGY  |  VOL 22 | OCTOBER 2021 | 1306–1315 | www.nature.com/natureimmunology

reduced viral replication compared to a single immunization with 30 μg (Fig. 4a, c). NHPs that received a single vaccination with 30 μg showed a trend toward reduced viral replication compared to control NHPs (Fig. 4a, c). On day 4 after challenge, the pattern was the same, with a significant reduction in viral replication in BAL for all vaccine groups compared to control NHPs, and for the 100-μg group compared to the 30-μg ×1 group (Fig. 4a, c). By day 7, while seven of eight control NHPs still had ~4 logs of sgRNA_E, there was no detectable sgRNA_E in six of eight NHPs in all vaccine groups (Fig. 4a), consistent with control of viral replication in the lower airway. To extend the analysis, we assessed viral titers in BAL and nasal swab (NS) samples following challenge (Fig. 4e, h). There was low to undetectable virus cultured from BAL in the majority of NHPs immunized with 30 and 100 μg ×2 at day 2 after challenge (Fig. 4e). Moreover, on day 2 after challenge, BAL viral titers and sgRNA were highly correlated (Fig. 4f, g), where there was no culturable virus from BAL of all NHPs with BAL sgRNA_N < 1.2 × 10^4 RNA copies per ml (Fig. 4g).

In contrast to the significant reduction of viral replication in the lower airway, at day 2 after challenge, the only significant reduction in viral replication for sgRNA_E (Fig. 4b) or sgRNA_N (Fig. 4d) in NS samples was in the 100-μg group. The differences in NHPs that received 100 μg ×2 were marginally lower compared to the groups that received 30 μg ×2 or 30 μg ×1 (P = 0.0273 and 0.0350, respectively), with no other significant pairwise differences (Fig. 4b, d). The groups were not significantly different at the later time points. A notable finding was that five of eight control NHPs still had ~4 log_{10} of sgRNA_E and all eight NHPs had sgRNA_N at day 7 in the NS samples (Fig. 4b, d), highlighting persistence of sgRNA following B.1.351 through day 7 after challenge. With that, there was ~4 log_{10} of sgRNA_E at day 7 in the NS samples of three of eight NHPs in the 100-μg ×2 group (Fig. 4b). Of note, six of eight animals had low to undetectable viral load in NS samples on day 2 after challenge in the 100-μg ×2 group (Fig. 4b). NS viral titers and sgRNA were highly correlated (Fig. 4a, b). Overall, these data show a significant reduction and rapid control of B.1.351 viral replication in the lower airways following vaccination with mRNA-1273 with more limited control in the upper airway and only in the 100-μg ×2 group.

Inflammation and viral load in lung tissue after challenge. To provide a further assessment of protection following vaccination, NHPs in each of the dose groups were assessed for virus-related pathology and the detection of viral antigen in the lung on day 8 after B.1.351 challenge. The severity of inflammation, which ranged from minimal to moderate, was similar across lung samples from NHPs that received the vaccine in doses of 100 μg ×2, 30 μg ×2 or 30 μg ×1 (Fig. 5). The inflammatory lesions in the lung were characterized by a mixture of lymphocytes, histiocytes and fewer polymorphonuclear cells associated with variably expanded alveolar capillaries, occasional areas of perivascular inflammation and type II pneumocyte hyperplasia. Two of four NHPs that received 30 μg ×1 of mRNA-1273 vaccine had trace amounts of virus detected in the lung. There was no detection of viral antigen in any lung sample from NHPs that received two doses of 30 or 100 μg. All four NHPs in the control group had variable amounts of viral antigen detected in the lung (Fig. 5 and Supplementary Table 1). These data corroborate viral replication data suggesting two doses of mRNA-1273 elicits substantial protection against lower-airway disease following B.1.351 challenge.

Post-challenge antibody and T cell responses in the airways. The assessment of antibody responses after challenge has been useful for determining whether viral replication in the BAL or NS samples is sufficient to boost vaccine-induced anamnestic S-specific antibody responses in these mucosal tissues. In BAL samples, WA-1 and B.1.351 S-specific IgG (Extended Data Fig. 4a) and IgA (Extended Data Fig. 4c, d) responses did not increase after challenge in NHPs that received two immunizations of 30 or 100 μg of mRNA-1273. However, by 14 days after challenge, there was an increase in WA-1 and B.1.351 S-specific IgG responses in NHPs that received 30 μg ×1 of mRNA-1273; in these NHPs IgG titers increased to levels that were similar to the NHPs that received 30 or 100 μg ×2 and higher than the unvaccinated controls (Extended Data Fig. 4a, b). In NS samples, there was an increase in WA-1 and B.1.351 S-specific IgG (Extended Data Fig. 4e, f) or IgA (Extended Data Fig. 4g, h) responses in unvaccinated NHPs and those immunized with 30 μg of mRNA-1273 once or twice; however, there were no anamnestic S-specific antibody responses in the 100-μg group. Overall, these data show that the increase in S-specific anamnestic antibody responses in both the BAL and NS samples are associated with viral replication in these mucosal sites and may explain the relatively rapid clearance of virus from NS samples in the 30-μg ×1 group seen from days 4 to 7 (Fig. 4b, d). We also assessed anamnestic S-specific T cell responses in BAL samples following challenge. CD8+ T cell responses, and not CD4+ T cells, were increased after challenge in BAL samples in 30-μg ×1 mRNA-1273-immunized NHPs and control NHPs (Extended Data Fig. 6). These data are consistent with their increased viral load in BAL samples compared to the two-dose vaccine groups.

Antibody correlates of protection. Assessing immune correlates of protection following vaccination is a critical aspect of vaccine development. It was reported that mRNA-1273 induced antibody responses are a mechanistic correlate for reducing viral replication against WA-1 challenge in NHPs. Here, B.1.351 S-specific IgG antibody titers at week 12, the time of challenge, also correlated strongly with reduction of sgRNA in both BAL (Fig. 6a, b) and NS (Fig. 6d) samples at day 2 after challenge. In addition, both pseudovirus and live viral neutralization correlated significantly with reduction of sgRNA in both BAL (Fig. 6b, c) and NS (Fig. 6e, f) samples.

In a recent report on correlates of protection following mRNA-1273 immunization in NHPs, we established a linear relationship between WA-1 S-specific antibody titers as defined by international units (IU) and subsequent sgRNA_2 d after SARS-CoV-2 WA-1 challenge. Here, we similarly converted pre-challenge WA-1 S-specific antibody titers to IU (Supplementary Table 2). Consistent with our previous NHP study, pre-challenge WA-1 S-specific IgG titers and previous sgRNA in BAL (Fig. 6g) and NS (Fig. 6h) samples at day 2 after challenge were negatively correlated. Based on a linear model, vaccinated animals that had S-specific IgG titers of ~100 and 120 IU ml−1 were predicted to have sgRNA_N and sgRNA_E, respectively, in BAL samples of approximately 2 log_{10} lower than the average for

Fig. 4 | Efficacy of mRNA-1273 against upper and lower respiratory B.1.351 viral replication. a–j. Twenty-four rhesus macaques were immunized and challenged as described in Extended Data Fig. 1, and compared to eight age-matched controls. BAL (a and c) and NS (b and d) samples were collected on days 2 (circles), 4 (squares), 7 (triangles) and 14 (inverted triangles) after challenge, where applicable, and viral replication was assessed by detection of SARS-CoV-2 E-specific (a and b) and N-specific (c and d) sgRNA. Viral titers were assessed by a 50% tissue culture infectious dose (TCID_{50}) assay for BAL collected on days 2 and 4 after challenge (e) and for NS on day 2 (h). Boxes and horizontal bars denote the IQR and medians, respectively; whisker end points are equal to the maximum and minimum values. In f, g, i, and j, plots show correlations between viral titers and sgRNA_E (f and i) and sgRNA_N (g and j) in BAL (f and g) and NS (i and j) 2 d after challenge. Data represent one independent experiment. Black and gray lines indicate linear regression line and 95% confidence interval, respectively. * and P represent Spearman’s correlation coefficients and corresponding two-sided P values, respectively; all P values were <0.0001. Symbols represent individual NHPs and may overlap for equal values.
PBS controls. Serum neutralizing activity was associated with control of viral replication; 13 of 14 of the NHPs with detectable pseudo-virus neutralizing activity against B.1.351 had BAL sgRNA_N < 10^5 (Fig. 6b). A similar linear relationship between S-specific antibody titers and viral replication in NS samples was apparent (Fig. 6c), although few of the NHP had NS sgRNA_N below 10^5.
As the antibody titers of S-specific IgG are very similar to those we previously reported using NHPs challenged with the SARS-CoV-2 WA-1 (ref. 38), we conducted an additional exploratory analysis of the data from both studies to investigate the consistency of the relationship between S-specific antibodies and BAL sgRNA, across the two different viruses. For low S-specific IgG levels, sgRNA was higher for animals challenged with B.1.351, but for animals with titers of S-specific IgG greater than approximately 100 IU ml\(^{-1}\), the estimated regression curve slopes are similar as are the levels that correspond to 2- to 4-log\(_{10}\) reductions in sgRNA in BAL samples compared to controls (Fig. 6i). These data suggest a similar relationship between S-specific IgG titers and lower-airway protection against WA-1, which contains S protein that is homologous to the mRNA-1273 insert, and the B.1.351 variant SARS-CoV-2 strain in NHPs.

Discussion

mRNA-1273 and BNT162b2 vaccines had \(-95\%\) efficacy in clinical trials performed in the United States, when WA-1 and p.Asp614Gly variants circulated most widely\(^{35,47}\). A critical issue is whether these and other vaccines will mediate protection against rapidly emerging variants. The B.1.351 variant is one of greatest concern compared to WA-1, p.Asp614Gly or B.1.1.7 based on the higher reduction in neutralization using vaccine sera\(^{41,11,25,16}\) and clinical trials showing lower efficacy against symptomatic infection\(^{30,31,12}\). However, recent data show the B.1.617.2 variant is now the predominant circulating strain worldwide, although it is less resistant to neutralization than B.1.351. Here, we present evidence that vaccine dose and number of immunizations effect protection against B.1.351 challenge. These data are consistent with a recent report showing vaccine effectiveness against PCR-confirmed infection with the B.1.351 variant is 16\% after one dose of BNT162b2 and 75\% after two doses\(^{11}\).

Antibodies have a critical role in mediating vaccine-elicited protection against SARS-CoV-2 in NHP models\(^{33,37,39,45,49}\). Here, we show there was a dose-dependent increase in WA-1 and B.1.351 S-specific and RBD-specific antibody titers and p.Asp614Gly and B.1.351 neutralization titers. Neutralizing activity against B.1.351 and B.1.617.2 were both increased following the second immunization. These data highlight the importance of a two-dose regimen for optimizing neutralization antibody responses, particularly against B.1.351 and likely for other VOCs with increased neutralization resistance. The frequency of S-specific T\(_{FH}\) and T\(_{eff}\) cell responses were also dose dependent, and CD8\(^{+}\) T cell responses detected only in NHPs receiving the 100-\(\mu\)g dose. These data are consistent with previous studies by us and others showing mRNA is a vaccine platform that induces T\(_{FH}\) cells and robust binding and neutralizing antibodies\(^{11,8,41,59}\).

As this study was our first to use the B.1.351 variant for challenge in NHPs, extensive sequence analyses were performed to propagate a challenge stock with an S sequence matched to the reference isolate. Naïve NHPs infected with the B.1.351 stock notably had peak sgRNA levels of \(-10^{2}\) copies per ml in BAL samples, which is higher than reported by us and others for challenge studies using the WA-1 strain\(^{33,37,39,45,49}\). Seven days after challenge, most of the control NHPs still had \(-10^{1}\) RNA copies per ml and copies per swab present in BAL and NS samples, respectively. This contrasts with the more rapid and complete reduction of viral replication following challenge with the WA-1 strain\(^{33,37,39,45,49}\) and is higher than viral loads typically seen in human infections. Whether the amount and persistence of the B.1.351 virus in vivo in this study relates to the challenge dose or suggests that this variant has inherent properties that make it more difficult to control and clear compared to the WA-1 strain\(^{33,32}\) is a focus of ongoing analyses.

Based on the high levels of sgRNA in BAL and NS samples, the dose of B.1.351 used here provided a stringent challenge for vaccine-elicited protection. We observed a significant reduction in viral replication in BAL samples at day 2 after challenge in groups that received 30 and 100 \(\mu\)g twice; six of eight NHPs that received the 100-\(\mu\)g vaccine regimen had no detectable sgRNA\(_E\) in BAL samples. Of note, while there was no detectable serum neutralizing activity against B.1.351 virus with a single immunization of 30\(\mu\)g, there was still a significant reduction in viral replication in BAL samples by day 4 after challenge compared to controls, with limited inflammation or viral antigen in lungs at day 8. These data are consistent with our recent study in which NHPs immunized with only 1 or 3\(\mu\)g of mRNA-1273 twice demonstrated a reduction in viral replication in BAL samples and limited lung pathology following WA-1 challenge despite absence of detectable neutralizing activity\(^{18}\). Potential mechanisms for lower-airway protection in the absence of detectable serum neutralizing antibodies include Fc effector functions and anamnestic responses after challenge. It is also possible that T cells contribute to control of viral replication in lower airways; however, no current evidence exists for viral control by T cells following vaccination or primary infection\(^{53}\) in the SARS-CoV-2 NHP model.

In contrast to high-level or complete protection observed in lower airways against B.1.351 challenge for all doses, control of
viral replication in upper airways was only observed in animals receiving two doses of 100 µg. These data are consistent with previous studies in NHPs showing higher amounts of antibody are required to reduce viral replication in upper than lower airways following mRNA-1273 vaccination. The implications of these findings on transmission of B.1.351 in vaccinated people are unknown. Of note, recent results from human vaccine trials show that there is greater protection against severe disease than mild disease against the B.1.351 variant following immunization with Ad26.CoV2 (ref. 29) or BNT162b2 (ref. 31). Serum antibody titers were strong predictors of reduced viral load in BAL and NS samples. These data are consistent with studies by us and others showing antibodies induced by vaccination or infection of NHPs protect against reinfection. Our modeling suggests that animals with S-specific IgG titers of approximately 100 IU ml⁻¹ reduce sgRNA levels in BAL samples by approximately 2 log₁₀, with further decrease of approximately 2 log₁₀ sgRNA for every 1-log₁₀ increase in IgG titer in IU ml⁻¹. We also noted that 13 of 14 animals with any detectable neutralizing antibodies against B.1.351 had BAL sgRNA_N < 10⁵ suggesting that vaccines eliciting low to undetectable B.1.351-specific neutralizing antibodies may still control viral replication in lower airways.

The NHP model has been critical for guiding vaccine development against COVID-19 in humans. This report provides evidence that a two-dose regimen with mRNA-1273 effectively protects against B.1.351. Importantly, these data show a two-dose regimen induces high neutralizing activity against the B.1.617.2 VOC and other variants in NHPs and humans. These data in conjunction with real-world clinical data will inform public health decisions on future vaccine boost requirements.

Methods

Propagation and characterization of viral stocks. VeroE6 cells were obtained from the American Type Culture Collection (ATCC; clone E6, CRL-1386). SARS-CoV-2/human/USA/CA-EHC-083E/2020 (referred to as the p.Asp614Gly variant) was derived from a residual nasopharyngeal swab collected from a patient of Emory Healthcare in March 2020. The isolation and sequencing were previously described. The B.1.351 variant isolate, kindly provided by A. Pekosz (JHU), was propagated once in Vero-TMPRSS2 cells (generated by VRC/National Institutes of Health [NIH]) to generate P2 viral stocks. Viral titers were determined by plaque assay on Vero-TMPRSS2 cells. Viral stocks were sequenced as described below and stored at −80°C until use.

Deep sequencing of virus isolate. Illumina-ready libraries were generated using NEBNext Ultra II RNA Prep reagents (New England Biolabs) as previously described. Briefly, we fragmented RNA, followed by double-stranded cDNA synthesis, end repair, and adapter ligation. The ligated DNA was then barcoded and amplified by a limited cycle PCR and the barcode Illumina libraries were sequenced by using a paired-end 150-bp protocol on a NextSeq 2000 (Illumina). Demultiplexed sequence reads were analyzed in the CLC Genomics Workbench v21.0.3 by (1) trimming for quality, length and adapter sequence; (2) mapping to the Wuhan-Hu-1 SARS-CoV-2 reference (GenBank accession no. NC_045512); (3) improving the mapping by local realignment in areas containing insertions and deletions (indels); and (4) generating both a sample consensus sequence and a list of variants. Default settings were used for all tools.

Titration of B.1.351 in golden Syrian hamsters. Hamster experiments were carried out in compliance with US NIH regulations and approval from the Animal Care and Use Committee of Bioqual. Challenge studies were conducted at Bioqual. Golden Syrian hamsters (Envigo, 089), aged 8- to 9-weeks old, were randomized into groups of ten based on weight, with each group containing a 1:1 male/female ratio. Hamsters were inoculated intranasally with a total dose of 1 × 10⁵–1 × 10⁶ PFUs of SARS-CoV-2 B.1.351 in a final volume of 100 µl split between each nostril. Body weight observations were made daily after infection.

Titration of B.1.351 in rhesus macaques. Three-year-old male and female rhesus macaques of Indian origin were sorted by age and weight and then stratified into three groups as determined by age and sex. Body weight observations were made daily after infection. PFUs of SARS-CoV-2 JHU B.1.351 P2 in a final volume of 100 µl at week 0. Naive aged-matched female, 3- to 12-year-old, Indian-origin rhesus macaques were sorted by sex, age and weight and then stratified into groups of five. NHPs were divided intramuscularly at week 0 and days 2, 4 and 6 after challenge. BAL and NS samples were collected and assayed for sRNA as detailed below.

Preclinical mRNA-1273 mRNA and lipid nanoparticle production process. A sequence-optimized mRNA encoding prefusion-stabilized SARS-CoV-2 S-2P−−4 protein was synthesized in vitro. The mRNA was purified by oligo-T affinity purification and encapsulated in a lipid nanoparticle through a modified ethanol-droplet nanoprecipitation process described previously.

Rhesus macaque model. NHP experiments were carried out in compliance with US NIH regulations and approval from the Animal Care and Use Committee of the VRC and Bioqual. Challenge studies were conducted at Bioqual. Male and female NHPs, 3- to 12-year-old, Indian-origin rhesus macaques were sorted by sex, age and weight and then stratified into groups of five. NHPs were divided intramuscularly at week 0 and days 2, 4 and 6 after challenge. BAL and NS samples were collected and assayed for sRNA as detailed below.

Quantification of SARS-CoV-2 RNA and sRNA. At the time of collection, NS samples were frozen in 1 ml of 1X PBS containing 1 µl of SUPERase-In RNase Inhibitor (Invitrogen) and BAL fluid was mixed with 1 ml of RNAzol BD containing 10 µl acetic acid and both were frozen at −80°C until extraction. Nasal specimens were thawed at 55°C, and the swab removed. The remaining area of nasal fluid was removed, and the specimen was frozen in 1 ml of 1X PBS into the right hind leg or 30 µg at week 0. Naive aged-matched NHPs were included as controls. At week 12 (7–8 weeks after boost or 12 weeks after the single vaccination), all NHPs were divided intramuscularly at week 0 and days 2, 4 and 6 after challenge. BAL and NS samples were collected and assayed for sRNA as detailed below.
control sample and reference standard of each plate. Analysis was performed with the MSD Discovery Workbench software, version 4.0. Calculated ELISA immunoassay parameters to measure binding antibody activities include interpolated concentrations or assigned arbitrary units (a.u. per ml) read from the standard curve.

Conversion to 4-plex readout to international units. Recently the arbitrary units were bridged to the WHO International Standard (provided in international units per ml (IU ml^-1)), and a conversion factor was calculated and confirmed. Parallelism was established for all three antigens (SARS-CoV-2 S-2P, RBD and N) between the MSD-provided reference standard and the WHO-provided international standard. Concentration assignments were performed and then confirmed both at MSD and as part of a multisite confirmation study.

Mesoscale ELISA for mucosal antibody responses. Using previously described methods, total S-specific IgG and IgA were determined by multi-ARRAY ELISA using MSD.

Lentiviral pseudovirus neutralization assay. As previously described, pseudotyped recombinant VSV-ΔG-derived luciferase virus, BHK21/WI-2 cells (Kerafast, HE1011) were transfected with the Wuhan-1 strain (Genbank no. MN908947.3) with a pA.S6p14Gly mutation, a luciferase reporter, lentivirus backbone and human transmembrane protease serine 2 (TMPRSS2) genes into HEK293T/17 cells (ATCC CRL-11268). Similarly, pseudoviruses containing S from B.1.351, P.1 and B.1.1.7 were produced. Supplementary Table 3 for reagent details. Viral titers were determined by focus-forming assay on VeroE6 cells (VRC/NIH) (to generate viral stocks. See Supplementary Table 3 for reagent details. For samples that did not neutralize at the limit of detection at 50%, a value of 20 was plotted and used for geometric mean calculations.

VSV pseudovirus neutralization assay. To make SARS-CoV-2 pseudotyped recombinant VSV-ΔG–firefly luciferase virus, BHK21/WI-2 cells (Kerafast, HE1011) were transfected with the Wuhan-1 strain (Genbank no. MN908947.3) S plasmid expressing full-length S with pA.S6p14Gly mutation or S of B.1.351. See Supplementary Table 3 for reagent details. After S plasmid transfection, cells were subsequently infected with VSV-ΔG–firefly-luciferase as previously described.

Neutralization assays were completed on A549-ACE2-TMPRSS2 cells, generated using lentivirus encoding hACE2-P2A-TMPRSS2, with serially diluted serum samples as previously described. For samples that did not neutralize at the limit of detection at 50%, a value of 20 was plotted and used for geometric mean calculations.

Focus-reduction neutralization test. Viruses were propagated in Vero-TMPRSS2 cells (VRC/NIH) (to generate viral stocks. See Supplementary Table 3 for reagent details. Viral titers were determined by focus-forming assay on VeroE6 cells (ATCC). Viral stocks were stored at –80°C until use. Focus-reduction neutralization neutralization assays were performed as previously described. In detail, samples were diluted at threefold in eight serial dilutions using DMEM (VWR, 45000-304) in duplicates with an initial dilution of 1:10 in a total volume of 60 ml. Serially diluted samples were incubated with an equal volume of SARS-CoV-2 (100–200 foci per well) at 37°C for 1 h in a round-bottomed 96-well culture plate. The antibody–virus mixture was then added to Vero cells and incubated at 37°C for 1 h. After incubation, the antibody–virus mixture was removed and 100 µl of prewarmed 0.85% methylocellulose (Sigma–Aldrich, M0512-250G) overlay was added to each well. Plates were incubated at 37°C for 24 h. After 24 h, methylocellulose overlay was removed, and cells were washed three times with PBS. Cells were then fixed with 2% parformaldehyde in PBS (Electron Microscopy Sciences) for 30 min. Following fixation, plates were washed twice with PBS and 100 µl of permeabilization buffer (0.1% BSA (VWR, 0332), saponin (Sigma, 47036-250G-P) in PBS) was added to the fixed Vero cells for 20 min. Cells were incubated with an anti-SARS-CoV-2 primary antibody directly conjugated to biotin (CR3022-biotin) for 1 h at RT. Next, the cells were washed 3x in PBS and avidin–HRP was added for 1 h at RT followed by three washes in PBS. Foci were visualized using TrueBlue HRP substrate (KPL, 5510-0050) and imaged on an ELISPOT reader (CTL). Antibody neutralization was quantified by counting the number of foci for each sample using the Viridot program. The neutralization titers were calculated as follows: 1 – (ratio of the mean number of foci in the presence of sera and foci at the highest dilution of the respective sera sample). Each specimen was tested in duplicate. The 50% focus-reduction neutralization test titers were interpolated using a four-parameter logistic in GraphPad Prism v9.0.2.4.3. For samples that did not neutralize at the limit of detection at 50%, a value of 5 was plotted and used for geometric mean calculations.

Intracellular cytokine staining. Cryopreserved peripheral blood mononuclear cells were thawed and rested overnight in a 37°C/5% CO2 incubator. The next morning, cells were stimulated with SARS-CoV-2 S-protein peptide pools (S1 and S2) that were matched to the vaccine insert (comprising 158 and 157 individual peptides, respectively, as 15-mers overlapping by 11 amino acids in 100% dimethyl sulfoxide (DMSO). IPT Peptides) at a final concentration of 2 µg ml^-1 in the presence of 3 µM monensin for 6 h. Negative controls received an equal concentration of dimethyl sulfoxide instead of peptides (final concentration of 0.5%). Intracellular cytokine staining was performed as described previously. The following monoclonal antibodies were used: CD3 APC-Cy7 (clone SP34.2, BD Biosciences), CD4 PE-Cy5 (clone 53-2.17, BD Biosciences), IFN-γ PE-Cy5 (clone J4-511, BD Biosciences), IL-2 BV750 (clone RPA-T8, BioLegend), CD45RA PE-Cy5 (clone 5H9, BD Biosciences), CC57 BV670 (clone G043H7, BioLegend), CCR5 CXCR5 PE (clone MUSUBE1, Thermofisher), CXC3 CXCL11 (clone IC6/CXCR3, BD Biosciences), PD-1 BV737 (clone EH12.1, BD Biosciences), ICOS PE-Cy7 (clone C398.4.A, BioLegend), CD69 ECD (clone TP1.53, Beckman Coulter), IFN-γ Ax700 (clone B27, BioLegend), IL-2 BV750 (clone MQ1-17H12, BD Biosciences), IL-4 BB700 (clone MP4-25D2, BD Biosciences), TNF-α FITC (clone Mab11, BD Biosciences), IL-17 BV421 (clone JES510-5A2, BD Biosciences), IL-17 BV605 (clone BL168, BioLegend), IL-21 Ax647 (clone 3A3-N2.1, BD Biosciences) and CD154 BV785 (clone 24-31, BioLegend). Aqua live/dead fixable dead cell stain kit (Thermo Fisher Scientific) was used to exclude dead cells. All antibodies were previously titrated to determine the optimal concentration. Samples were acquired on a BD FACSymphony flow cytometer and analyzed using FlowJo version 9.9.6 (Treestar) following the gating scheme in Extended Data Fig. 7.

Statistical analysis. Graphs show data from individual NHPs with dotted lines indicating assay limits of detection. Groups were compared with the Kruskal–Wallis test, followed by pairwise two-sided Wilcoxon rank-sum tests with Holm’s adjustment on the set of pairwise tests if the Kruskal–Wallis test was significant, for the primary analysis of viral load at day 2 in the BAL and NS samples, as well as other comparisons between dose groups. Correlations were estimated and tested using Spearman’s nonparametric method. Linear regression was used to explore the relationship between antibody levels and sgRNA, including quadratic terms for comparing the newly generated data and those previously published, with likelihood-ratio tests to compare models and assess interaction effects.

Reporting Summary. Further information on research design is available in the Nature Research Reporting Summary linked to this article.

Data availability. The datasets generated during and/or analyzed during the current study are available from the corresponding author on reasonable request. Source data are provided with this paper.

Extended Data Fig. 1 | Study design: Ability of mRNA-1273 to protect NHP against B.1.351 challenge. Nonhuman primates (NHP), Rhesus macaques (n = 8/group), were immunized with mRNA-1273 on the following schedule: Group 1: 0 and 4 weeks, 100 µg; Group 2: 0 and 5 weeks, 30 µg; Group 3: week 0, 30 µg. Naive aged-matched NHP were included as controls. At week 12, animals were challenged with a total of 5 × 10^5 PFU of SARS-CoV-2 B.1.351. The viral inoculum was administered as 3.75 × 10^5 PFU in 3 mL intratracheally (IT) and 1.25 × 10^6 PFU in 1 mL intranasally (IN) in a volume of 0.5 mL into each nostril. Sera were collected at weeks 7 and week 12. Bronchoalveolar lavages (BAL) and nasal washes were also collected at week 7. Sera, BAL, and nasal washes were collected post-challenge on days 2, 4, 7, and 14, as indicated. Lung pathology was assessed on day 8 post-challenge in a subset of animals (n = 4/group).
Extended Data Fig. 2 | Temporal neutralizing antibody responses following mRNA-1273 immunization. Rhesus macaques were immunized according to Supplementary Fig. 1. Sera collected at weeks 0, 2, 7, and 12 were assessed for SARS-CoV-2 D614G (A), and B.1.351 (B) lentiviral-based pseudovirus neutralization. Data represents one independent experiment. Circles represent individual NHP and may overlap where values are equal; lines represent geometric mean titers (GMT). Dotted lines indicate neutralization assay limits of detection. Arrows point to immunization weeks.
Extended Data Fig. 3 | Correlations of humoral antibody analyses. Rhesus macaques were immunized according to Supplementary Fig. 1c. Plots show correlations between SARS-CoV-2 WA-1 S-specific IgG, B.1.351 S-specific IgG, WA-1 RBD-specific IgG, B.1.351 RBD-specific IgG, D614G lentiviral-based pseudovirus neutralization, B.1.351 lentiviral-based pseudovirus neutralization, D614G VSV-based pseudovirus neutralization, B.1.351 VSV-based pseudovirus neutralization, D614G focus reduction neutralization, and B.1.351 focus reduction neutralization at week 12. Data represents one independent experiment. Circles represent individual NHP, where colors indicate mRNA-1273 dose as defined in Supplementary Fig. 1. Dotted lines indicate assay limits of detection. Black and gray lines indicate linear regression and 95% confidence interval, respectively. 'r' and 'p' represent Spearman’s correlation coefficients and corresponding two-sided p-values, respectively.
Extended Data Fig. 4 | Characterization of B.1.351 viral isolate. A SARS-CoV-2 B.1.351 clinical isolate was first passaged (P1) at Johns Hopkins University (JHU) on Vero cells then passaged again (P2) on Vero/TMPRSS2 cells. P1 and P2 underwent shotgun deep sequencing. (A) Alignment of S protein consensus sequence, where pink and gray indicate variant amino acid position and missing sequence data, respectively. (B) Syrian hamsters (n = 10/group) were infected with \(1 \times 10^3\) (gray), \(1 \times 10^4\) (black), or \(1 \times 10^5\) (red) dilution of JHU B.1.351 P2 and monitored for weight loss for 15 days post-infection. Circles and error bars represent means and SEM, respectively. (C-D) Rhesus macaques (n = 3/group) were infected with \(2.4 \times 10^5\) (black) or \(2.4 \times 10^6\) (red) PFU of JHU B.1.351 P2 and viral replication was assessed by detection of SARS-CoV-2 E-specific sgRNA in BAL (C) and NS (D) on days 2, 4, and 6 post-infection. Data represents one independent experiment. Boxes and horizontal bars denote the interquartile ranges (IQR) and medians, respectively; whisker end points are equal to the maximum and minimum values. Dotted lines indicate assay limits of detection.
Extended Data Fig. 5 | Mucosal antibody responses following SARS-CoV-2 challenge in mRNA-1273-immunized NHP. Rhesus macaques were immunized and challenged according to Supplementary Fig. 1. BAL (A–D) and nasal washes (E–H) collected at week 7 (filled circles) and days 2 (circles), 4 (squares), 7 (triangles), and 14 (inverted triangles) post-challenge were assessed for SARS-CoV-2 WA-1 (A, C, E, G) and B.1.351 (B, D, F, H) S-specific IgG (A–B, E–F) and IgA (C–D, G–H) by MULTI-ARRAY ELISA. Data represents one independent experiment. Boxes and horizontal bars denote the IQR and medians, respectively; whisker end points are equal to the maximum and minimum values. Symbols represent individual NHP.
Extended Data Fig. 6 | T cell responses following SARS-CoV-2 challenge in mRNA-1273-immunized. Rhesus macaques were immunized according to Extended Data Fig. 1. Intracellular cytokine staining was performed on BAL cells at week 27 (filled circles) and days 7 (triangles) and 14 (inverted triangles) post-challenge to assess T cell responses to SARS-CoV-2 S protein peptide pools, S1 and S2 (A, C, E) and N (B, D, F). Responses to S1 and S2 individual peptide pools were summed. Cytokine frequencies were measured from memory T cells as defined by CD45RA and CCR7. (A-B) Th1 responses (IFNg, IL-2, or TNF), (C-D) Th2 responses (IL-4 or IL-13), (E-F) CD8 T cell responses (IFNg, IL-2, or TNF). Data represents one independent experiment. Boxes and horizontal bars denote IQR and medians, respectively; whisker end points are equal to the maximum and minimum values. Circles represent individual NHP. Dotted lines are set to 0%.
Extended Data Fig. 7 | Flow cytometry gating tree. T cell populations were selected by subsequent gating: first single cells, followed by live/SSC low cells, then CD3+/FSC low cells, and finally CD4+ and CD8+ T cells. To measure IL-21 production and CD40L expression from Tfh, CD4 T cells were gated first on central memory (CM) T cells (CCR7+CD45RA−) then CXCR5+CM cells followed by PD-1+ICOS+ cells to identify Tfh. Subsequently, from Tfh, CD69+IL-21+ and CD69+CD154+ cells were gated. Cytokine production from total memory (TotM) CD4 and CD8 T cells was measured by first gating on total memory cells (central memory CCR7+CD45RA− plus effector memory CCR7−CD45RA− plus terminal effector memory CCR7−CD45RA+ T cells) while excluding naive CCR7+CD45RA+ T cells, then CD69+ cytokine+ gates were drawn on total memory T cells.
Reporting Summary

Nature Portfolio wishes to improve the reproducibility of the work that we publish. This form provides structure for consistency and transparency in reporting. For further information on Nature Portfolio policies, see our Editorial Policies and the Editorial Policy Checklist.

Statistics

For all statistical analyses, confirm that the following items are present in the figure legend, table legend, main text, or Methods section.

n/a Confirmed

- The exact sample size (n) for each experimental group/condition, given as a discrete number and unit of measurement
- A statement on whether measurements were taken from distinct samples or whether the same sample was measured repeatedly
- The statistical test(s) used AND whether they are one- or two-sided
  Only common tests should be described solely by name; describe more complex techniques in the Methods section.
- A description of all covariates tested
- A description of any assumptions or corrections, such as tests of normality and adjustment for multiple comparisons
- A full description of the statistical parameters including central tendency (e.g. means) or other basic estimates (e.g. regression coefficient) AND variation (e.g. standard deviation) or associated estimates of uncertainty (e.g. confidence intervals)
- For null hypothesis testing, the test statistic (e.g. F, t, r) with confidence intervals, effect sizes, degrees of freedom and P value noted
  Give P values as exact values whenever suitable.
- For Bayesian analysis, information on the choice of priors and Markov chain Monte Carlo settings
- For hierarchical and complex designs, identification of the appropriate level for tests and full reporting of outcomes
- Estimates of effect sizes (e.g. Cohen’s d, Pearson’s r), indicating how they were calculated

Our web collection on statistics for biologists contains articles on many of the points above.

Software and code

Policy information about availability of computer code

Data collection
No data collection software was used.

Data analysis
Prism v7.0, Prism v9.0.2, Prism v9.0.2.4.3, and MSD Discovery Workbench software, Version 4.0

For manuscripts utilizing custom algorithms or software that are central to the research but not yet described in published literature, software must be made available to editors and reviewers. We strongly encourage code deposition in a community repository (e.g. GitHub). See the Nature Portfolio guidelines for submitting code & software for further information.

Data

Policy information about availability of data

All manuscripts must include a data availability statement. This statement should provide the following information, where applicable:

- Accession codes, unique identifiers, or web links for publicly available datasets
- A description of any restrictions on data availability
- For clinical datasets or third party data, please ensure that the statement adheres to our policy

The authors declare that the data supporting the findings of this study are available within the paper and its supplementary information files. The datasets generated during and/or analyzed during the current study are available from the corresponding author on reasonable request.
Field-specific reporting

Please select the one below that is the best fit for your research. If you are not sure, read the appropriate sections before making your selection.

- [ ] Life sciences
- [ ] Behavioural & social sciences
- [ ] Ecological, evolutionary & environmental sciences

For a reference copy of the document with all sections, see https://nature.com/documents/nr-reporting-summary-flat.pdf

Life sciences study design

All studies must disclose on these points even when the disclosure is negative.

**Sample size**

Sample size for animal experiments was determined based on criteria set by institutional ACUC. SARS-CoV-2 is a novel virus and animal challenge models are still being optimized. There is not sufficient data available for the rhesus macaque challenge model to power an experiment to show a statistical difference between vaccine doses and is not our goal. In this study, we aim to (1) assess immunogenicity with different doses and vaccine regimens (2) determine the durability of immunity and protection following vaccination. We are proposing to immunize eight animals at each vaccine dose. We anticipate reduced viral titers, clinical and radiographic signs and reduced histopathological changes in the lungs of the vaccinated animals. Eight animals is sufficient to provide >80% power to detect significant protection as determined by the following endpoints: sgRNA and viral PCR in day 2 post-challenge BAL and NS. The information garnered by this experiment will inform subsequent experiments aimed at identifying a serological correlate of protection from SARS-CoV-2 disease.

**Data exclusions**

No data were excluded.

**Replication**

Animal studies were completed once as these are NHP studies. All immunoassay testing was completed in technical duplicate or triplicate with 1 replicate, unless otherwise stated in methods, and all replicates were successful.

**Randomization**

Allocation of animals was randomized based on age and weight into groups of 8.

**Blinding**

Blinding was not completed as assays were completed by the same team that immunized animals.

Reporting for specific materials, systems and methods

We require information from authors about some types of materials, experimental systems and methods used in many studies. Here, indicate whether each material, system or method listed is relevant to your study. If you are not sure if a list item applies to your research, read the appropriate section before selecting a response.

### Materials & experimental systems

| n/a | Involved in the study |
|-----|-----------------------|
| [ ] | Antibodies |
| [ ] | Eukaryotic cell lines |
| [ ] | Palaeontology and archaeology |
| [ ] | Animals and other organisms |
| [ ] | Human research participants |
| [ ] | Clinical data |
| [ ] | Dual use research of concern |

### Methods

| n/a | Involved in the study |
|-----|-----------------------|
| [ ] | ChiP-seq |
| [ ] | Flow cytometry |
| [ ] | MRI-based neuroimaging |

#### Antibodies

- Antibodies used: ICS - costimulatory antibodies anti-CD28 and anti-CD49d (clones CD28.2 and 9F10, BD Biosciences)
- Validation: No validation.

#### Eukaryotic cell lines

Policy information about cell lines

- **Cell line source(s):** HEK293T/17 (ATCC #CRL-11268), Vero E6 (ATCC) Vero-TMPRSS2 [made in-house - VRC), ACE-2-expressing 293T (ATCC) cells [provided by Michael Farzan, Scripps Research Institute]
- **Authentication:** None of the cells lines were authenticated.
- **Mycoplasma contamination:** All cell lines were tested negative for mycoplasma.
Animals and other organisms

Policy information about studies involving animals: ARRIVE guidelines recommended for reporting animal research

| Animal Type                  | Description                                                                                     |
|------------------------------|------------------------------------------------------------------------------------------------|
| Laboratory animals           | Hamsters: Male and female Golden Syrian hamsters (Envigo, O89), aged 8-9 weeks old. NHP: Male and female, 3-12 year-old, Indian-origin rhesus macaques. |
| Wild animals                 | The study did not use wild animals.                                                              |
| Field-collected samples      | The study did not use field-collected samples.                                                   |
| Ethics oversight             | Animal experiments were carried out in compliance with US National Institutes of Health regulations and approval from the Animal Care and Use Committee of the Vaccine Research Center and Bioqual, Inc. |

Note that full information on the approval of the study protocol must also be provided in the manuscript.

Flow Cytometry

Plots

Confirm that:
- The axis labels state the marker and fluorochrome used (e.g. CD4-FITC).
- The axis scales are clearly visible. Include numbers along axes only for bottom left plot of group (a ‘group’ is an analysis of identical markers).
- All plots are contour plots with outliers or pseudocolor plots.
- A numerical value for number of cells or percentage (with statistics) is provided.

Methodology

| Sample preparation            | Rhesus macaque PBMC were isolated from whole blood using a Ficoll gradient and cryopreserved. |
| Instrument                    | BD FACSsymphony A5                                                                             |
| Software                      | Dive software was used to collect the data and FlowJo was used to analyze the data.           |
| Cell population abundance     | N/A as cells were not sorted.                                                                   |
| Gating strategy               | T cell populations were selected by subsequent gating: first single cells, followed by live/SSC low cells, then CD3+/FSC low cells, and finally CD4+ and CD8+ T cells. To measure IL-23 production and CD40L expression from Th1, CD4 T cells were gated first on central memory (CM) T cells (CCR7+CD45RA+) then CXCR5+ CM cells followed by PD-1+CD45+ cells to identify Th1. Subsequently, from Th1, CD69+IL-21+ and CD69+CD154+ cells were gated. Cytokine production from total memory (TotM) CD4 and CD8 T cells was measured by first gating on total memory cells (central memory CCR7+CD45RA+ plus effector memory CCR7+CD45RA+ plus terminal effector memory CCR7-CD45RA+ T cells) while excluding naïve CCR7+CD45RA+ T cells, then CD69+cytokine+ gates were drawn on total memory T cells. |

Tick this box to confirm that a figure exemplifying the gating strategy is provided in the Supplementary Information.
