Kinetic Theory for Matter Under Extreme Conditions

James Dufty and Jeffrey Wrighton

Department of Physics, University of Florida

(Dated: November 15, 2018)

Abstract

The calculation of dynamical properties for matter under extreme conditions is a challenging task. The popular Kubo-Greenwood model exploits elements from equilibrium density functional theory (DFT) that allow a detailed treatment of electron correlations, but its origin is largely phenomenological; traditional kinetic theories have a more secure foundation but are limited to weak ion-electron interactions. The objective here is to show how a combination of the two evolves naturally from an exact short time limit for the generator of the effective single electron dynamics governing time correlation functions. This provides a theoretical context for the current DFT-related approach, the Kubo-Greenwood model, while showing the nature of its corrections. The method is to calculate the exact short time dynamics in the single electron subspace, for a given configuration of the ions. This differs from the usual kinetic theory approach in which an average over the ions is performed as well. In this way the effective ion-electron interaction is treated exactly and shown to be determined from DFT. The correlation functions have the random phase approximation for an inhomogeneous system, but with renormalized ion-electron and electron-electron potentials. The dynamic structure function, density response function, and electrical conductivity are calculated as examples. The static local field corrections in the dielectric function are identified in this way. The current analysis is limited to semi-classical electrons (quantum statistical potentials), so important quantum conditions are excluded. However, a quantization of the kinetic theory is identified for broader application while awaiting its detailed derivation.
I. INTRODUCTION

Recent interest in matter under extreme conditions (e.g., high pressure materials, warm dense matter, and high temperature plasmas) has been stimulated in part by new experimental access to such states [1]. Thermodynamic properties can be addressed in a controlled way by finite temperature density functional theory (DFT) for the electrons [2] in conjunction with \textit{ab initio} molecular dynamics (AIMD) for the ions [3]. The two tools of DFT and MD are appropriate for such states since strong coupling and bound states can be treated without explicit approximation. Dynamical phenomena are more problematical, particularly for the electrons which require quantum dynamics in general. Current many-body theories of condensed matter physics or plasma physics have questionable applicability. Kinetic theories, classical or quantum, typically have the limitation to free electrons and weak ion-electron correlations. Models which utilize DFT quantities (such as the Kubo-Greenwood model [4] below) remove this restriction at the price of phenomenology and unknown context. The objective here is to demonstrate a kinetic theory for electrons in a given configuration of ions, obtained in an exact limit that incorporates the DFT model and well-known many-body effects of electron dynamics. The derivation is semi-classical but makes no explicit restrictions regarding coupling among the ions and electrons, or bound and free electron states.

The system of interest here is that of electrons in equilibrium with a frozen disordered configuration of ions in the grand canonical ensemble. In applications, properties for this system are found by averaging over different ionic configurations. The properties of interest are time correlation functions that determine transport coefficients, scattering cross sections, and other equilibrium dynamic electron fluctuations of linear response. The state conditions include possible strong coupling and other effects of correlations such as dynamical fluctuations. These are the types of difficult cases that are handled well by DFT for thermodynamic calculations, and it is tempting to think (hope) that such detailed information can be exploited somehow for the analysis of dynamics as well. A practical implementation of this idea, the Kubo-Greenwood model (KG) [4], is obtained by replacing the many-body electron-ion Hamiltonian by a sum of single particle Hamiltonians. Though in principle arbitrary, invariably they are chosen to be non-interacting particles governed by the Kohn-Sham potential which includes the external ion field. The latter appears in the variational
Euler equation of DFT and is determined from the exchange-correlation free energy as a functional of the equilibrium density \[2\]. In the KG model the Kohn-Sham Hamiltonian, originally defined to determine the equilibrium density, is promoted to a generator for the dynamics. Furthermore, it is assumed to represent in a mean field way the effects of the true Coulomb interactions which it replaces. The origin of this picture of Kohn-Sham quasi-particles and the conditions for its validity have not been established. Doing so is a primary objective of the present work.

In earlier work the authors considered time correlation functions for a semi-classical electron gas in the presence of a single fixed ion, and derived a kinetic equation whose form is exact at short times \[5\]. It has a single particle dynamics with a "renormalized" external potential from the electron - ion interaction. In addition, there is a collective Vlasov (random phase approximation) dynamics with a renormalized electron - electron interaction. Both of these effective interactions are determined from derivatives of the semi-classical exchange - correlation free energy. In particular, the electron - ion interaction is precisely the Kohn-Sham potential of the KG model. Here, that description is extended to time correlation functions for electrons in a disordered many-ion background with configurations sampled from an equilibrium ensemble. An important distinguishing feature of this kinetic equation relative to others is that only electron degrees of freedom are averaged out to define the single electron subspace. No ion average is performed. This allows a detailed description of the average electron interaction with each ion, setting the framework for connection with DFT. A brief summary of these ideas is given in reference \[6\].

The exact analysis of the generator for the dynamics at short times at present has been established only for semi-classical electrons. Thus strong degeneracy and other extreme quantum effects are not captured in the exact analysis here. This limits the conditions for applicability, as described briefly in section \[VI\]. However, the primary objective here is to show by example how the many-body problem can be controlled, and to indicate a pathway to the basis for the KG model. In section \[V\] a straightforward quantization of this semi-classical result is given as a temporary "placeholder" for the detailed quantum derivation paralleling that given here.

In the next section, the time correlation functions and their representation in terms of linear kinetic theory are introduced. The formal definition of the generator for the electron dynamics in the single electron subspace is defined. While generally time dependent, its
exact form is evaluated at \( t = 0 \) in Appendix A. No limitations are placed on the strength of correlations or coupling. This gives a Markov dynamics for the time correlation functions in which the generator is taken to have the same form at later times as well. The result has the structure of a kinetic theory in the random phase approximation, extended to an inhomogeneous system due to the external forces of the ions. However, that force is renormalized to be derived from the Kohn-Sham potential (the ion field plus the first functional derivative of the excess free energy), and the electron-electron Coulomb potential is renormalized to the electron-electron direct correlation function (second functional derivative of the excess free energy). As illustrations, the dynamical structure function, density response function, and frequency dependent electrical conductivity are determined from this kinetic equation. The dielectric function is considered, and the associated static local field corrections are identified. In the last section these results are summarized and discussed.

II. TIME CORRELATION FUNCTIONS FROM KINETIC THEORY

Consider a system of \( N_e \) electrons in equilibrium with \( N_i \) fixed ions. The Hamiltonian is

\[
H = \sum_{\alpha=1}^{N_e} \left( \frac{1}{2} m v_{\alpha}^2 + V_{ei}(r_{\alpha}, \{R\}) \right) + \frac{1}{2} \sum_{\alpha\neq\gamma=1}^{N_e} V_{ee}(r_{\alpha\gamma})
\]

where the interaction potential for the electrons with the \( N_i \) fixed ions is

\[
V_{ei}(r_{\alpha}, \{R\}) = \sum_{\gamma=1}^{N_i} V_{ei}(|r_{\alpha} - R_{\gamma}|).
\]

The notation \( \{R\} \) denotes a dependence on the collection of \( N_i \) fixed ion coordinates \( R_{\gamma} \). Also, \( r_{\alpha} \) and \( v_{\alpha} \) are the position and velocity of electron \( \alpha \). In the quantum case all interactions are pure Coulomb. The analysis below is entirely within classical mechanics for both ions and electrons. Residual quantum effects must be retained to prevent collapse due to the electron-ion singularity at zero separation. In the quantum case such collapse is avoided due to diffraction effects. These can be accounted for in the classical representation by regularizing the Coulomb potential within a distance of the order of the thermal de Broglie wavelength. Similar effects occur for the electron-electron interaction, which also has an additional effect due to Pauli exclusion. The use of such modified potentials has a long history, leading to many different forms originating from different contexts for their derivation.\[4\]
The resulting classical representation allows MD simulation of opposite charge components. One of the first was an application to hydrogen plasmas [8]; a more recent simulation in the current context is that of references [9, 10]. The specific forms, or their limitations, are not central to the discussion here. Instead, the objective is to demonstrate how the many-body physics can be analysed in a controlled way to make contact with current phenomenology and to clarify its context.

The equilibrium time correlation functions for two observables $A$ and $B$ in the grand canonical ensemble are

$$
\langle A(t)\delta B; \{\mathbf{R}\} \rangle = \sum_{N_e} \int d\{x\} \rho_e(\{\mathbf{R}\}, \{x\}) A(t, \{\mathbf{R}\}, \{x\}) \delta B(\{\mathbf{R}\}, \{x\}),
$$

(3)

$$
\rho_e(\{\mathbf{R}\}, \{x\}) = e^{\beta\Omega(\{\mathbf{R}\})} e^{-\beta(H(\{\mathbf{R}\})-\mu)}
$$

(4)

where $\delta B = (B - \langle B \rangle)$. The set of phase variables $\{x\} = \{x_1, \ldots, x_{N_e}\}$ denote the positions and velocities of each electron, e.g., $x_1 \leftrightarrow r_1, v_1$. The passive dependence on the ion coordinates has been made explicit here, but will be suppressed in the following for simplicity of notation, except where needed.

The time dependence of $A(t, \{x\})$ is generated by the Hamiltonian (1) from the initial value $A(\{x\})$. The phase functions $A(\{x\})$ and $B(\{x\})$ denote some observables of interest, composed of sums of single particle functions

$$
A = \sum_{\alpha=1}^{N_e} a(x_\alpha), \quad B = \sum_{\alpha=1}^{N_e} b(x_\alpha).
$$

(5)

The special form (5) allows reduction of the $N_e$ electron average to a corresponding average in the single electron subspace, by partial integration over $N_e - 1$ degrees of freedom (see Appendix A)

$$
\langle A(t)\delta B \rangle = \int dx n(r) \phi(v) a(x) \mathcal{B}(x, t).
$$

(6)

Here, $n(r)$ is the equilibrium number density for electrons at a position $r$, and $\phi(v)$ is the Maxwell-Boltzmann velocity distribution. The function $\mathcal{B}(x, t)$ at $t = 0$ is linearly related to the single particle phase function $b(x)$ in (5)

$$
\mathcal{B}(x, 0) = \mathcal{B}(x) = b(x) + \int dx' n(r') \phi(v') (g(r, r') - 1) b(x'),
$$

(7)

and $g(r, r')$ is the pair correlation function for two electrons at $r$ and $r'$ in the presence of the ion configuration $\{\mathbf{R}\}$. Finally, the time dependence of $\mathcal{B}(x, t)$ is given by the linear kinetic
equation in the single particle phase space

$$\partial_t \overline{b}(x, t) + \int dx' L(x, x'; t) \overline{b}(x', t) = 0,$$

also derived in Appendix A. All of the results up to this point are still exact.

III. MARKOVIAN KINETIC EQUATION AND ITS RELATION TO DFT

The generator of dynamics, $L(x, x'; t)$, defined formally in Appendix A, is an appropriate point for the introduction of approximations. Typically, matter under extreme conditions does not admit any small parameter expansions because the treatment must include possible strong Coulomb coupling. Here, a Markov approximation is chosen that does not prejudice such conditions. Furthermore there is no scattering context so that the electrons may be free or bound to the ions. A Markov kinetic equation has a generator whose form does not change in time. Hence, a practical expression can be determined from $L(x, x'; t = 0)$ and assumed to hold as well for all later times. One of the first developments of this idea for classical time correlation functions was given by Lebowitz, Percus, and Sykes [11], and for the quantum case by Boercker and Dufty [12]. The primary difference here is the presence of the external forces due to the ions. The analysis follows that of reference [5], and the details are given in Appendix B with the resulting kinetic equation

$$\left( \partial_t + \mathbf{v} \cdot \nabla - m^{-1} \nabla \mathbf{r} \mathcal{V}_{ie} (\mathbf{r}) \cdot \nabla \mathbf{v} \right) \overline{b}(x, t) = -\mathbf{v} \cdot \nabla \beta \int dx' \mathcal{V}_{ee} (\mathbf{r}, \mathbf{r}') \phi (v') \mathcal{n}(\mathbf{r}') \overline{b}(x', t). \quad (9)$$

To understand this result, note that if $\mathcal{V}_{ie}$ and $\mathcal{V}_{ee}$ were their (regularized) Coulomb interactions [9] would be the random phase approximation (RPA) in the presence of the external ion potential. Here, however, those potentials have been renormalized by the initial equilibrium correlations. The left hand side of (9) describes single particle motion in an external renormalized ion - electron potential $\mathcal{V}_{ie} (\mathbf{r})$

$$\mathcal{V}_{ie} (\mathbf{r}, \{\mathbf{R}\}) \equiv -\beta^{-1} \ln \mathcal{n}(\mathbf{r}, \{\mathbf{R}\}). \quad (10)$$

The right side describes dynamical correlations for this single particle motion with a renormalized electron - electron potential

$$\mathcal{V}_{ee} (\mathbf{r}, \mathbf{r}', \{\mathbf{R}\}) = -\beta^{-1} c (\mathbf{r}, \mathbf{r}', \{\mathbf{R}\}). \quad (11)$$
Here \( c(\mathbf{r}, \mathbf{r}', \{ \mathbf{R} \}) \) is the electron direct correlation function determined in terms of \( g(\mathbf{r}, \mathbf{r}', \{ \mathbf{R} \}) \) through the Ornstein-Zernicke equation \[13\], \((A13)\). For weak coupling, \((10)\) and \((11)\) reduce to their Coulomb forms. The explicit dependence on \( \{ \mathbf{R} \} \) has been restored at this point to emphasize that the electron subsystem is non-uniform due to the presence of the ions.

These renormalizations are due to static correlations of the equilibrium ensemble and provide the desired connection to DFT. To see this, note that the electron system is an inhomogeneous electron gas due to the presence of the ions. The associated equilibrium free energy \( F \) is a functional of the corresponding inhomogeneous density, and is traditionally separated into a non-interacting part, \( F^{(0)} \), and an interacting part, \( F^{(1)} \),

\[
F(\beta \mid n) = F^{(0)}(\beta \mid n) + F^{(1)}(\beta \mid n).
\]

The equilibrium density for evaluation of these functionals is determined from the ion - electron potential by

\[
\frac{\delta F(\beta \mid n)}{\delta n(\mathbf{r}, \{ \mathbf{R} \})} = \mu - V_{ei}(\mathbf{r}, \{ \mathbf{R} \}),
\]

with \( V_{ei}(\mathbf{r}, \{ \mathbf{R} \}) \) given by \((2)\). Equation \((13)\) can be rearranged as

\[
\frac{\delta F^{(0)}(\beta \mid n)}{\delta n(\mathbf{r}, \{ \mathbf{R} \})} = \mu - v_{KS}(\mathbf{r}, \{ \mathbf{R} \}),
\]

where \( v_{KS}(\mathbf{r}, \{ \mathbf{R} \}) \) is known in DFT as the Kohn-Sham potential

\[
v_{KS}(\mathbf{r}, \{ \mathbf{R} \}) \equiv V_{ei}(\mathbf{r}, \{ \mathbf{R} \}) + \frac{\delta F^{(1)}(\beta \mid n)}{\delta n(\mathbf{r}, \{ \mathbf{R} \})}.
\]

Furthermore, for the classical system considered here \( F^{(0)}(\beta \mid n) \) can be evaluated exactly to give

\[
\frac{\delta F^{(0)}(\beta \mid n)}{\delta n(\mathbf{r}, \{ \mathbf{R} \})} = \beta^{-1} \ln n(\mathbf{r}, \{ \mathbf{R} \}).
\]

Consequently the renormalized ion - electron potential \((10)\) becomes

\[
V_{ie}(\mathbf{r}, \{ \mathbf{R} \}) = -\frac{\delta F^{(0)}(\beta \mid n)}{\delta n(\mathbf{r}, \{ \mathbf{R} \})} = v_{KS}(\mathbf{r}, \{ \mathbf{R} \}) - \mu.
\]

With this identification it is instructive to write the kinetic equation \((9)\) as

\[
\partial_t \bar{b}(\mathbf{r}, t) - \{ h_{KS}(x), \bar{b}(x, t) \} = \frac{1}{\phi(v) n(\mathbf{r})} \int dx' \left\{ V_{ee}(\mathbf{r}, \mathbf{r}') \phi(v) n(\mathbf{r}) \phi(v') n(\mathbf{r}') \bar{b}(x', t) \right\}.
\]

7
Here \{,\} denotes the Poisson bracket, and \( h_{KS} \) is the Kohn-Sham Hamiltonian,

\[
h_{KS}(x) = \frac{1}{2}mv^2 + v_{KS}(r).
\]  

(19)

As noted in the Introduction a common approximation for evaluating Green-Kubo time correlation expressions for transport coefficients is the replacement of the actual Hamiltonian with Coulomb interactions by a sum of single particle Kohn-Sham Hamiltonians \[4\]. The resulting kinetic theory representation is the same as \[13\] with zero on the right side. The semi-classical analysis here provides an important context for that approximation, justifying the introduction of the Kohn-Sham dynamics and making the connection to DFT.

In addition, the renormalized electron-electron potential \[11\] is related to the excess free energy functional by

\[
\mathcal{V}_{ee}(r, r', \{R\}) = c(r, r', \{R\}) = -\frac{\delta^2 \beta F^{(1)}(\beta, \{R\} | n)}{\delta n(r, \{R\}) \delta n(r', \{R\})} = -\frac{\delta \beta v_{KS}(r, \{R\})}{\delta n(r', \{R\})}.
\]

(20)

Thus all of the input for the kinetic equation can be obtained from DFT, even for conditions of interest for strong coupling.

IV. DYNAMIC STRUCTURE, RESPONSE, AND CONDUCTIVITY

The correlation functions for the dynamic structure factor, density response function, and electrical conductivity are closely related. The dynamic structure factor is determined from the Fourier transform of the density-density time correlation function

\[
C(r, r', t) = \langle \hat{n}(r, t) \delta \hat{n}(r') \rangle, \quad \hat{n}(r) = \sum_{\alpha=1}^{N_e} \delta(r_{\alpha} - r).
\]

(21)

The density response function is proportional to its time derivative \[14\]

\[
\chi(r, r', t) = \beta \partial_t C(r, r', t).
\]

(22)

Finally, using the continuity equation

\[
\partial_t \hat{n}(r, t) + \nabla \cdot \hat{j}(r, t) = 0, \quad \hat{j}(r) = \sum_{\alpha=1}^{N_e} \delta(r_{\alpha} - r)v_{\alpha},
\]

(23)

the response function is related to the current-current correlation function

\[
\partial_t \chi(r, r', t) = -\beta \left\langle \nabla \hat{j}(r, t) \nabla' \hat{j}(r') \right\rangle,
\]

(24)
which determines the electrical conductivity.

The general solution to the kinetic equation is given in Appendix C. When applied to $C(\mathbf{r}, \mathbf{r}', t)$ and $\chi(\mathbf{r}, \mathbf{r}', t)$ integral equations for each are obtained,

\[
C(\mathbf{r}, \mathbf{r}', t) = C_0(\mathbf{r}, \mathbf{r}', t) + \int_0^t d\tau \int d\mathbf{r}'' \chi_{KG}(\mathbf{r}, \mathbf{r}'', t - \tau) \int d\mathbf{r}''' V_{ee}(\mathbf{r}'', \mathbf{r}''') C(\mathbf{r'''}, \mathbf{r}', \tau) \quad (25)
\]

and

\[
\chi(\mathbf{r}, \mathbf{r}', t) = \chi_{KG}(\mathbf{r}, \mathbf{r}', t) + \int_0^t d\tau \int d\mathbf{r}'' \chi_{KG}(\mathbf{r}, \mathbf{r}'', t - \tau) \int d\mathbf{r}''' V_{ee}(\mathbf{r}'', \mathbf{r}''') \chi(\mathbf{r'''}, \mathbf{r}', \tau) \quad (26)
\]

In each of these the non-interacting Kubo-Greenwood response function occurs

\[
\chi_{KG}(\mathbf{r}, \mathbf{r}', t - \tau) = -\beta \int d\mathbf{v} \phi(\mathbf{v}) n(\mathbf{r}) e^{-\mathcal{L}_{KG}(t-\tau)} \mathbf{v} \cdot \nabla_{\mathbf{r}} \delta(\mathbf{r} - \mathbf{r}') \quad (27)
\]

Here $\mathcal{L}_{KG}$ is the generator for the Kubo-Greenwood dynamics

\[
\mathcal{L}_{KG} \equiv \mathbf{v} \cdot \nabla_{\mathbf{r}} - m^{-1} \nabla_{\mathbf{r}} V_{ie}(\mathbf{r}) \cdot \nabla_{\mathbf{v}}. \quad (28)
\]

The correlation function $C_0(\mathbf{r}, \mathbf{r}', t)$ has the same dynamics but also the exact initial conditions

\[
C_0(\mathbf{r}, \mathbf{r}', t) = \int d\mathbf{v} \phi(\mathbf{v}) n(\mathbf{r}) e^{-\mathcal{L}_{KG} t} (\delta(\mathbf{r} - \mathbf{r}') + n(\mathbf{r}') (g(\mathbf{r}, \mathbf{r}') - 1)). \quad (29)
\]

The solutions to (25) and (26) are obtained by first taking their Laplace transforms

\[
\tilde{C}(\mathbf{r}, \mathbf{r}', z) = \int_0^\infty d\tau e^{-zt} C(\mathbf{r}, \mathbf{r}', t), \quad \tilde{\chi}(\mathbf{r}, \mathbf{r}', z) = \int_0^\infty d\tau e^{-zt} \chi(\mathbf{r}, \mathbf{r}', t). \quad (30)
\]

Then the solutions are

\[
\tilde{C}(\mathbf{r}, \mathbf{r}', z) = \int d\mathbf{r}'' \tilde{\epsilon}^{-1}(\mathbf{r}, \mathbf{r}'', z) \tilde{C}_0(\mathbf{r}'', \mathbf{r}', z) \quad (31)
\]

and

\[
\tilde{\chi}(\mathbf{r}, \mathbf{r}', z) = \int d\mathbf{r}'' \tilde{\epsilon}^{-1}(\mathbf{r}, \mathbf{r}'', z) \tilde{\chi}_{KG}(\mathbf{r}'', \mathbf{r}', z), \quad (32)
\]

where $\tilde{\epsilon}^{-1}(\mathbf{r}, \mathbf{r}'', z)$ is the inverse function for

\[
\tilde{\epsilon}(\mathbf{r}, \mathbf{r}', z) = \delta(\mathbf{r} - \mathbf{r}') - \int d\mathbf{r}'' \chi_{KG}(\mathbf{r}, \mathbf{r}'', z) V_{ee}(\mathbf{r}'', \mathbf{r}'). \quad (33)
\]
A. Dielectric function and local field corrections

The function \( \tilde{\tau}(r, r', z) \) is closely related to the dielectric function defined by

\[
\int dr'' V(r-r'') \tilde{\chi}(r'', r', z) = \int dr'' \epsilon^{-1}(r, r'', z) (\epsilon(r'', r') - \delta(r''-r')).
\]  

(34)

It has the form

\[
\epsilon(r, r', z) = \delta(r-r') + \int dr'' V(r-r'') \chi_{KG}(r'', r', z) D^{-1}(r'', r', z)
\]

(35)

with

\[
D(r, r', z) = \delta(r-r') - \int dr'' \Delta(r, r'', z) \chi_{KG}(r'', r', z).
\]

(36)

The leading term on the right side of (36) gives the random phase approximation. The second term contains the "dynamic local field corrections" \( \Delta(r, r'', z) \). In the present case with \( \tilde{\chi}(r, r', z) \) given by (32) the local field corrections \( \Delta(r, r', z) \) are found to be

\[
\Delta(r, r', z) \to V_{ee}(r, r') - V(r-r').
\]

(37)

These are the static field corrections due to correlations in the definition of \( V_{ee}(r, r') \). [20]

\[
V_{ee}(r, r') = -\beta^{-1} c_{ee}(r, r') = \frac{\delta^2 F_{e}^{(1)}(\beta, \{R\} | n)}{\delta n(r, \{R\}) \delta n(r', \{R\})}.
\]

(38)

If the Hartree energy is subtracted from \( F_{e}^{(1)} \) the remainder is the exchange-correlation free energy \( F_{xc} \) and

\[
V_{ee}(r, r') - V(r-r') = \frac{\delta^2 F_{xc}(\beta, \{R\} | n)}{\delta n(r, \{R\}) \delta n(r', \{R\})}.
\]

(39)

Thus the static local field corrections are the second functional derivative of \( F_{xc} \).

B. Electrical conductivity

The frequency dependent electron conductivity is given by its classical Green-Kubo form [14]

\[
\sigma(\omega) = \text{Re} \int_0^{\infty} dt e^{i\omega t} \psi(t), \quad \psi(t) = \frac{\beta}{3V} \left\langle \left\langle \hat{J}(t) \cdot \hat{J} \right\rangle \right\rangle_i.
\]

(40)

The double brackets \( \langle\rangle_i \) denote an average over the electron degrees of freedom, followed by an average over the ion configurations (see below). The total current \( \hat{J} \) is the volume integral of the current density \( \hat{j} \)

\[
\hat{J} = \hat{j}(k = 0), \quad \hat{j}(k) = \int dr e^{ik \cdot r} \hat{j}(r).
\]

(41)
The Fourier transform of (24) gives
\[ \partial_t \langle \chi(k, k', t) \rangle_i = \beta k_m k'_n \left\langle j_m(k, t) \tilde{j}_n(k') \right\rangle_i. \] (42)

Once the ion configuration average has been performed the system is isotropic so this becomes
\[ \partial_t \langle \chi(k, k', t) \rangle_i = -\frac{1}{3} \beta k^2 \left\langle \tilde{j}(k, t) \cdot \tilde{j}(-k) \right\rangle_i \delta_{kk'}. \] (43)

Therefore the current autocorrelation function in the expression for the conductivity, (40), is
\[ \psi(t) = -\frac{1}{V} \lim_{k \to 0} k^{-2} \partial_t \langle \chi(k, -k, t) \rangle_i, \] (44)

where the response function is given by (32). If the electron screening of \( \tau(r, r', z) \) could be neglected the Kubo-Greenwood model would be obtained,
\[ \psi(t) \to -\frac{1}{V} \lim_{k \to 0} k^{-2} \partial_t \langle \chi_{KG}(k, -k, t) \rangle_i. \] (45)

In practice, the conductivity is calculated directly from \( \langle j(0, t) \cdot \tilde{j}(0) \rangle \) in the Kubo-Greenwood approximation for each ion configuration, without reference to the density response function. These conductivities for the disordered systems are then averaged over all configurations.

V. QUANTUM KINETIC EQUATION

In the quantum case the electron correlation function (6) becomes
\[ \langle A(t) \delta B \rangle = Tr_1 f(1) a(1) \bar{b}(1, t), \] (46)

where the trace is taken over a single electron Hilbert space, and the classical equilibrium one electron distribution function \( n(r) \phi(v) \) has been replaced by its corresponding quantum operator \( f(1) \). Similarly, \( a(1) \) and \( \bar{b}(1, t) \) are the operators generalizing the phase space functions \( a(x) \) and \( \bar{b}(x, t) \). The analysis of Appendix A follows in an analogous way [12]. However, the simplifications of the higher order correlations from the equilibrium hierarchy, (B11) and (B12), are more complex. Furthermore, recognition of \( \ln n(r) \) as the functional derivative of the non-interacting free energy functional no longer applies in the quantum case. Hence, to date the exact evaluation of the generator for the dynamics \( L(t = 0) \) in the quantum case has not been accomplished.
In the meantime an alternative route is to quantize the classical result derived here. The most direct path is to write the kinetic equation in the equivalent form

\[ \partial_t \bar{b}(1,t) - \{ h_{KS}(1), \bar{b}(1,t) \} = f^{-1}(1) \text{Tr}_2 \{ \mathcal{V}_{ee}(1,2), f(1)f(2)\bar{b}(2,t) \}, \quad (47) \]

and to quantize it by replacing Poisson brackets by their corresponding commutators. This gives the operator equation

\[ \partial_t \bar{b}(1,t) + i \{ h_{KS}(1), \bar{b}(1,t) \} = -f^{-1}(1) \text{Tr}_2 i \{ \mathcal{V}_{ee}(1,2), f(1)f(2)\bar{b}(2,t) \}. \quad (48) \]

The Kohn-Sham Hamiltonian is the operator corresponding to (19) with the Kohn-Sham potential determined in the same way as (15) from the free energy functional for the quantum system. Similarly, \( \mathcal{V}_{ee}(1,2) \) is determined from that functional as given in (11) and (20).

Equation (48) is the quantum random phase approximation for a system of electrons among a configuration of the ions, with renormalized potentials. Its classical limit is (9). The random phase approximation without renormalization (weak coupling limit) has been established directly for the quantum case [12].

VI. DISCUSSION

The objectives here have been two-fold. The first is to describe a kinetic theory for electrons in a disordered array of ions that is both practical and free from any assumptions regarding electron-electron or ion-electron coupling. In particular, the purpose is to do so without the need for distinction of free and bound electrons. This was accomplished by an exact evaluation of the generator for time dependence at \( t = 0 \), followed by the assumption that this generator is a reasonable approximation at all later times (Markov assumption). The second objective is to make contact between a controlled many-body theory and the phenomenology of the Kubo-Greenwood model. This was accomplished by observing that the short time generator has a single particle dynamics that is the same as the Kubo-Greenwood model, including the ion-electron force determined from the Kohn-Sham potential of equilibrium DFT. In addition, the context of that model was exposed, requiring additional effects of electron-electron screening via a renormalized potential also determined from DFT. The correlation functions have the structure of the random phase approximation for an inhomogeneous system, modified by these potentials from DFT.
Although these conceptual issues of strong coupling, connection to DFT, and clarification of the Kubo-Greenwood model have been addressed, the practical application of the kinetic equation developed here is limited by its semi-classical nature. Some of the most interesting state conditions of warm, dense matter include strong electron degeneracy, outside the domain of the regularized quantum potentials assumed here. For these cases the quantum theory of section V should be a useful practical tool. The detailed origin for this equation and its limitations (e.g., absence of electron-electron collisional effects) will be provided elsewhere.

The semi-classical electrons assumed here nevertheless have an important domain of validity where degeneracy is weak but electron-electron and electron-ion coupling can be strong. They have been used in early MD simulations of hydrogen plasmas [8], where electron coupling strengths of order one were studied at weak to moderate degeneracy. Subsequent simulations have demonstrated that such potentials can describe the transition from fully ionized to atomic states, but fail for molecular formation [15]. More recently simulations to test the accuracy of different forms of these effective quantum potentials have been reported [9, 10].

The role of the frozen ion configuration is passive in this analysis of the electron dynamics. In practice the systems of interest are ions and electrons in which both species are mobile. It is assumed, however, that the ions are effectively static on the time scale for electron properties. In this case the latter properties are calculated as here for a given configuration, and then an average performed over configurations. The latter are sampled from an ab initio simulation of the ions [2]. A discussion of the effect of ion motion is deferred to a later point [5].

VII. ACKNOWLEDGEMENT

The authors are grateful to S.B. Trickey for his many constructive comments on an earlier draft. This work was supported by the US DOE Grant de-sc0002139.
Appendix A: Kinetic theory

The dynamics of \( \langle A(t) \delta B \rangle_e \) is conveniently expressed in terms of the fundamental correlation function \( G(x, x'; t) \)

\[
\langle A(t) \delta B \rangle = \int dx dx' a(x) G(x, x'; t) b(x'), \quad (A1)
\]

\[
G(x, x'; t) = \langle f(x, t) (f(x') - \langle f(x') \rangle) \rangle, \quad f(x) = \sum_{\alpha=1}^{N_e} \delta(x - x_\alpha). \quad (A2)
\]

This gives the representation \( (6) \)

\[
\langle A(t) \delta B \rangle = \int dx \, n(r) \phi(v) a(x) \bar{b}(x, t), \quad (A3)
\]

with the identification

\[
\bar{b}(x, t) = \frac{1}{n(r) \phi(v)} \int dx' G(x, x'; t) b(x'). \quad (A4)
\]

The initial value is

\[
\bar{b}(x, 0) = \bar{b}(x) = \frac{1}{n(r) \phi(v)} \int dx' G(x, x'; 0) b(x'). \quad (A5)
\]

Evaluation of \( G(x, x'; 0) \) is straightforward from the definitions of the one and two particle equilibrium distribution functions

\[
n(r_1) \phi(v_1) = \sum_{N_e>1} N_e Tr_{2,..N_e} \rho(\{R\}, \{x\}), \quad (A6)
\]

\[
n(r_1)n(r_2) g(r_1, r_2) \phi(v_1) \phi(v_2) = \sum_{N_e>2} N_e (N_e - 1) Tr_{3,..N_e} \rho(\{R\}, \{x\}), \quad (A7)
\]

where \( \rho(\{R\}, \{x\}) \) is the \( N \) electron grand canonical distribution function of \( (4) \). The result is

\[
G(x, x'; 0) = n(r) \phi(v) (\delta(x - x') + \phi(v') n(r') h(r, r')) , \quad (A8)
\]

with the hole function defined by \( h(r, r') = g(r, r') - 1 \). This leads to \( (7) \)

\[
\bar{b}(x) = b(x) + \int dx' n(r') \phi(v') h(r, r') b(x'). \quad (A9)
\]

A formally exact kinetic equation follows from definition of the inverse for \( G(x, x'; t) \)

\[
\int dx'' G^{-1}(x, x''; t) G(x'', x'; t) = \delta(x - x') \quad (A10)
\]
and differentiation of (A4)

\[
\partial_t \tilde{b}(x, t) = \frac{1}{n(r)\phi(v)} \int dx' \partial_t G(x, x'; t)b(x')
\]

\[
= \frac{1}{n(r)\phi(v)} \int dx' dx'' \left( \partial_t G(x, x'; t) \right) G^{-1}(x', x''; t)n(r'')\phi(v'')\tilde{b}(x'', t).
\] (A11)

The generator for the dynamics is identified as

\[
\partial_t \tilde{b}(x, t) + \int dx' L(x, x'; t) \tilde{b}(x', t) = 0,
\] (A12)

\[
L(x, x'; t) \equiv -\frac{1}{n(r)\phi(v)} \int dx'' \left( \partial_t G(x, x''; t) \right) G^{-1}(x'', x'; t)n(r')\phi(v').
\] (A13)

**Appendix B: Evaluation of \(L(x, x'; 0)\)**

The Markov approximation is based on using \(L(x, x'; 0)\) as the generator for dynamics,

\[
L(x, x'; 0) = \frac{1}{n(r)\phi(v)} \int dx'' \partial_t G(x, x'', t) \mid_{t=0} G^{-1}(x'', x'; 0)n(r')\phi(v').
\] (B1)

Consider first \(G^{-1}(x'', x'; 0)\) in the form

\[
G^{-1}(x, x'; 0) = \frac{1}{n(r)\phi(v)} \delta(x - x') - c(r, r').
\] (B2)

Then this obeys the inverse condition (A10) with (A8) if \(c(r, r')\) obeys the equation

\[
c(r, r') = h(r, r') - \int dr'' h(r, r'') n(r'') c(r'', r') .
\] (B3)

This definition for \(c(r, r')\) is the Ornstein-Zernicke equation [13].

Next \(\partial_t G(x, x''; t) \mid_{t=0}\) is evaluated from its definition (A2) and Newton’s equations

\[
(\partial_t + v \cdot \nabla_r - m^{-1}\nabla_r V_{ie}(r) \cdot \nabla_v) f(x, t)
\]

\[
= \int dx' (\nabla_r V_{ee}(r, r')) \cdot m^{-1}\nabla_v (f(x, t)f(x', t) - \delta(x - x')f(x', t)).
\] (B4)

This gives

\[
\partial_t G(x, x'; t) \mid_{t=0} = -\left(v \cdot \nabla_r - m^{-1}\nabla_r V_{ie}(r) \cdot \nabla_v \right) G(x, x'; 0)
\]

\[
+ \int dx'' (\nabla_r V_{ee}(r, r'')) \cdot m^{-1}\nabla_v \left( (f(x) f(x'') - \delta(x - x'') f(x'')) (f(x') - f(x')) \right).
\] (B5)
The average in the second term on the right side can be evaluated using the expressions

\[ \langle f (x) \rangle = \phi (v) \ n (r) \]  \hspace{1cm} (B6)

\[ \langle f (x) f (x') \rangle = \delta (x - x') \phi (v) \ n (r) + \phi (v) \phi (v') \ n (r) \ n (r') \ g (r, r') \]  \hspace{1cm} (B7)

\[ \langle (f (x) f (x'')) - \delta (x - x'') f (x'') \rangle f (x') = (\delta (x - x') + \delta (x'' - x')) \phi (v) \phi (v'') \ n (r) \ n (r'') \ g (r, r'') + \phi (v) \phi (v') \phi (v'') \ n (r) \ n (r') \ n (r'') \ g (r, r', r''). \]  \hspace{1cm} (B8)

Here \( g (r, r', r'') \) is defined from the three-electron reduced distribution function

\[ n(r_1)n(r_2)n(r_3)g(r_1, r_2, r_3) \phi (v_1) \phi (v_2) \phi (v_3) \]

\[ = \sum_{N_e > 3} N_e (N_e - 1) (N_e - 2) \text{Tr}_{3e \cdots N_e} \rho (\{R\}, \{x\}). \]  \hspace{1cm} (B9)

Then (B5) becomes

\[ \partial_t G(x, x'; t) \mid_{t=0} = - (v \cdot \nabla_r - m^{-1} \nabla_r V_{ee} (r) \cdot \nabla_r) G(x, x'; 0) \]

\[ - \beta v \cdot (\nabla_r V_{ee} (r, r')) \phi (v) \phi (v') n (r) \ n (r') \ g (r, r') \]

\[ + n (r) m^{-1} \nabla_v \cdot \delta (x - x') \phi (v) \int \text{d}r'' (\nabla_r V_{ee} (r, r'')) \ n (r'') \ g (r, r'') \]

\[ - n (r) n (r') \phi (v') \phi (v) \beta v \cdot \int \text{d}r'' (\nabla_r V_{ee} (r, r'')) \ n (r'') \ (g (r, r', r'') - g (r, r'')) \].  \hspace{1cm} (B10)

The two integrals on the right side can be evaluated using the first two equations of the BBGKY hierarchy

\[ \int \text{d}r'' (\nabla_r V_{ee} (r, r'')) \ n (r'') \ g (r, r'') = - \beta^{-1} \nabla_r \ln n (r) - \nabla_r V_{ie} (r), \]  \hspace{1cm} (B11)

\[ \int \text{d}r'' (\nabla_r V_{ee} (r, r'')) \ n (r'') \ (g (r, r', r'') - g (r, r'')) = - (\nabla_r V_{ee} (r)) \ g (r, r') \]

\[ - (\nabla_r V_{ie} (r) + \beta^{-1} \nabla_r \ln n (r)) \ h (r, r') - \beta^{-1} \nabla_r h (r, r') \]  \hspace{1cm} (B12)

to get

\[ \partial_t G(x, x'; t) \mid_{t=0} = - (v \cdot \nabla_r - m^{-1} \nabla_r V_{ie} (r) \cdot \nabla_r) G(x, x'; 0) \]

\[ - n (r) m^{-1} \nabla_v \cdot \delta (x - x') \phi (v') \left( \beta^{-1} \nabla_r \ln n (r) + \nabla_r V_{ie} (r) \right) \]

\[ + n (r) n (r') \phi (v') \phi (v) \beta v \cdot (\nabla_r V_{ie} (r, r') + \beta^{-1} \nabla_r \ln n (r)) \ h (r, r') \]

\[ + n (r) n (r') \phi (v') \phi (v) \beta v \cdot \beta^{-1} \nabla_r h (r, r'). \]  \hspace{1cm} (B13)
Finally, eliminate the delta function in the second term of the right side using (A6)

\[
\partial_t G(x, x'; t) \big|_{t=0} = -\left( v \cdot \nabla_r + m^{-1} \beta^{-1} \nabla_r \ln n(r) \cdot \nabla_v \right) G(x, x'; 0) \\
+ n(r) n(r') \phi(v') \phi(v) \beta v \cdot \beta^{-1} \nabla_r h(r, r') .
\]  

(B14)

Together with (B1), (B2), and (B3) this gives the desired result

\[
L(x, x'; 0) = \left( v \cdot \nabla_r - m^{-1} \beta^{-1} \nabla_r \ln n(r, \{R\}) \cdot \nabla_v \right) \delta(x - x') \\
- n(r', \{R\}) \phi(v') v \cdot \nabla_r c(r, r', \{R\}) .
\]  

(B15)

Appendix C: Solution to Markov kinetic equation

A formal solution to the kinetic equation (9) for \( \bar{b}(x, t) \) is

\[
\bar{b}(x, t) = e^{-\mathcal{L}_{KG} t} \bar{b}(x) - \int_0^t d\tau e^{-\mathcal{L}_{KG} (t-\tau)} \int d\tau' \beta \nu_{ee}(r, r') I(r', \tau),
\]  

(C1)

where the generator for the effective single particle (Kubo-Greenwood) dynamics is

\[
\mathcal{L}_{KG} \equiv v \cdot \nabla_r - m^{-1} \nabla_r \nu_{ie}(r) \cdot \nabla_v,
\]  

(C2)

and the source term \( I(r, t) \) is

\[
I(r, t) \equiv \int d\nu \phi(v) n(r) \bar{b}(x, t).
\]  

(C3)

Use of (C1)–(C3) gives an integral equation for \( I(r, t) \),

\[
I(r, t) = I_0(r, t) + \int_0^t d\tau \int d\tau' \chi_{KG}(r, r', t - \tau) \int d\tau'' \nu_{ee}(r', r'') I(r'', \tau),
\]  

(C4)

with

\[
I_0(r, t) \equiv \int d\nu \phi(v) n(r) e^{-\mathcal{L}_{KG} t} \bar{b}(x)
\]  

(C5)

and

\[
\chi_{KG}(r, r', t - \tau) = -\beta \int d\nu \phi(v) n(r) e^{-\mathcal{L}_{KG} (t-\tau)} v \cdot \nabla_r \delta(r - r') .
\]  

(C6)
1. Dynamic structure factor

The dynamic structure factor is determined from the density-density time correlation function

\[ C(r, r', t) = \langle \hat{n}(r, t) \delta \hat{n}(r') \rangle, \quad (C7) \]

which corresponds to \( a(x_1) = \delta (r_1 - r) \) and \( b(x_1) = \delta (r_1 - r') \) in (6). Then with (C1) the dynamic structure factor obeys the integral equation

\[ C(r, r', t) = C_0(r, r', t) + \int_0^t d\tau \int d\mathbf{r}'' \chi_{KG}(r, r'', t - \tau) \int d\mathbf{r}''' \nu_{ee} (r'', r''') C(r''', r', \tau), \quad (C8) \]

where

\[ C_0(r, r', t) = n(r) \int d\mathbf{v} \phi (v) e^{-t\mathcal{L}_{KG}} (\delta (r - r') + n(r') h (r, r')). \quad (C9) \]

The solution to the linear equation (C8) is obtained first by defining the Laplace transform

\[ \tilde{f}(z) = \int_0^\infty d\tau e^{-zt} f(t), \quad (C10) \]

to get

\[ \tilde{C}(r, r', z) = \tilde{C}_0(r, r', z) + \int d\mathbf{r}'' \tilde{\chi}_{KG}(r, r'', z) \int d\mathbf{r}''' \nu_{ee} (r'', r''') \tilde{C}(r''', r', z). \quad (C11) \]

Next define

\[ \epsilon(r, r', z) = \delta (r - r') - \int d\mathbf{r}'' \chi_{KG}(r, r'', z) \nu_{ee} (r'', r'), \quad (C12) \]

so the solution to (C11) is

\[ \tilde{C}(r, r', z) = \int d\mathbf{r}'' \epsilon^{-1}(r, r'', z) \tilde{C}_0(r'', r', z). \quad (C13) \]

2. Density response function

The density response function is related to the density correlation function by (22)

\[ \chi(r, r', t) = \beta \partial_t C(r, r', t). \quad (C14) \]

Then differentiating (C8) gives
\[ \chi(r, r', t) = \chi_0(r, r', t) + \int dr'' \chi_{KG}(r, r'', 0) \int dr''' V_{ee}(r'', r''') C(r''', r', t) \]
\[ - \int_0^t d\tau \int dr'' \beta \partial_\tau \chi_{KG}(r, r'', t - \tau) \int dr''' V_{ee}(r'', r''') C(r''', r', \tau) , \]
\[ = \chi_0(r, r', t) + \int dr'' \chi_{KG}(r, r'', t) \int dr''' V_{ee}(r'', r''') C(r''', r', 0) \]
\[ + \int_0^t d\tau \int dr'' \chi_{KG}(r, r'', t - \tau) \int dr''' V_{ee}(r'', r''') \chi(r'''', r', \tau) , \tag{C15} \]
\[ \chi(r, r', t) = \chi_{KG}(r, r', t) \]
\[ + \int_0^t d\tau \int dr'' \chi_{KG}(r, r'', t - \tau) \int dr''' V_{ee}(r'', r''') \chi(r'''', r', \tau) . \tag{C16} \]

The Ornstein-Zernicke equation \([B3]\) has been used to make the identification
\[ \chi_{KG}(r, r', t) = \chi_0(r, r', t) + \int dr'' \chi_{KG}(r, r'', t) \int dr''' V_{ee}(r'', r''') C(r''', r', 0) . \tag{C17} \]

Taking the Laplace transform of \((C16)\) gives the solution
\[ \tilde{\chi}(r, r', z) = \int dr'' \tau^{-1}(r, r'', z) \tilde{\chi}_{KG}(r'', r', z) , \tag{C18} \]
where \(\tau^{-1}(r, r', z)\) is the inverse function associated with
\[ \tau(r, r', z) = \delta(r - r') - \int dr'' \chi_{KG}(r, r'', z) V_{ee}(r'', r') . \tag{C19} \]
