(Dated: February 2, 2008)

We derive general expressions for non-energy weighted and energy-weighted cluster sum rules for systems of three charged particles. The interferences between pairs of particles are found to play a substantial role. The energy-weighted sum rule is usually determined by the kinetic energy operator, but we demonstrate that it has similar additional contributions from the angular momentum and parity dependence of two- and three-body potentials frequently used in three-body calculations.

The importance of the different contributions is illustrated with the dipole excitations in $^4$He. The results are compared with the available experimental data.

I. MOTIVATION

The use of sum rules in quantum mechanics is well established and abundantly applied for many different systems [1, 2]. The prominent examples are the transitions from a given quantum state induced by an electromagnetic multipole operator. For any multipole operator acting on an initial state, the sum of all the related transition probabilities multiplied by powers of the excitation energy are completely determined by the properties of the initial state [3, 4].

The sum rules exist in general for any many-body quantum system. Of specific interest are those systems where the constituents clusterize, such that the degrees of freedom can be divided into the internal ones corresponding to each cluster, and those associated with the relative motion of the clusters [5]. Then the different multipole operators can be decomposed into terms depending on the intrinsic coordinates of each cluster, and an additional term depending only on the relative coordinates of the centers of mass of the clusters. This operator structure then leaves two sum rules showing the same decomposition, the sum rules associated with each individual cluster (depending only on the properties of the initial cluster state), plus the cluster sum rule (depending on the properties of the few-body initial wave function). Examples are found in [6, 7], where the dipole non-energy weighted and dipole energy-weighted sum rules are obtained for many-body systems clusterizing into a two-body system.

When a clusterized system can be properly described as a few-body system where the internal cluster degrees of freedom are frozen, only the cluster sum rules remain, corresponding to the much smaller Hilbert space of ground and excited states of the relative cluster motion. This kind of few-body descriptions have been extensively used in nuclear physics during the latest 10-15 years in connection with halos and weakly bound states in general [8, 9, 10, 11, 12]. To get accurate three-body wave functions the Faddeev decomposition with different Jacobi coordinates is employed in coordinate space computations [13]. The unavoidable transformation from one set of Jacobi coordinates to another complicates the structure of the cluster sum rules, especially when more than one of the three particles is charged.

The purpose of this work is to generalize the dipole two-body cluster sum rule as in [6, 7] to three-body systems for any multipolarity. Advanced three-body calculations employ partial wave dependent pair interactions and state dependent three-body potentials, and these complications must therefore also be taken into account in derivations of the cluster sum rules. Typically, the two-body interactions are adjusted independently for each partial wave in order to reproduce the available properties of the corresponding two-body system, e.g. bound state and resonance energies, and phase shifts [14, 15]. These interactions are then essentially non-local through their angular momentum dependence. Also, it is common to introduce effective angular momentum and parity dependent three-body forces for fine-tuning the crucial total energies of the three-body states. Since the multipole transition operators carry both angular momentum and parity they do not commute, in general, with the angular momentum dependent two- and three-body potentials. Thus, the energy weighted cluster sum rule should then be rederived including the corresponding contributions in addition to the usual kinetic energy term. In all cases we must include contributions from the three Faddeev components which are expressed in their respective Jacobi coordinates.

In section [11] we briefly introduce the coordinates used, and summarize some important relations and definitions. In section [13] we derive the non-energy weighted sum rule.

Examples are found in [6, 7], where the dipole non-energy weighted and dipole energy-weighted sum rules are obtained for many-body systems clusterizing into a two-body system.
The energy-weighted sum rule is obtained in section [IV] which is divided into three subsections corresponding to the contributions from the kinetic energy operator, the partial wave dependent two-body potentials, and the (total angular momentum) $J^\pi$-dependent three-body forces. As an illustration, in section [V] we investigate the dipole excitations in $^6\text{He}$ and compare with the available experimental data. We close the paper with a short summary and the conclusions. A few intermediate expressions obtained in the derivations have been collected in the appendix.

II. THE TRANSITION PROBABILITY

We assume three clusters with masses $m_i$ and charges $z_i$ ($i=1,2,3$), described by coordinates $r_i$, and with the three-body center-of-mass at $R$. The three sets of mass-scaled Jacobi coordinates are $\{x_i,y_i\} \equiv \{\rho,\alpha_i,\Omega_{x_i},\Omega_{y_i}\}$, where $\rho$ is the hyperradius and $\{\alpha_i,\Omega_{x_i},\Omega_{y_i}\}$ are the five hyperangles corresponding to the Jacobi set $i$, see for instance [13]. The connection between the Cartesian and the mass-scaled Jacobi coordinates is given by

$$r_j - r_k = \sqrt{\frac{m_N(m_j+m_k)}{m_j m_k}} x_i,$$

$$r_i - R = \sqrt{\frac{m_N(m_j+m_k)}{m_i M}} y_i,$$

where $M=m_i+m_j+m_k$ and $m_N$ is the normalization mass. The transformation between different sets of Jacobi coordinates is given by

$$y_i = -x_i \sin \phi_{ik} - y_k \cos \phi_{ik},$$

$$\tan \phi_{ik} = (-1)^p \sqrt{\frac{m_j M}{m_i m_k}} \text{(if } i \neq k\text{), and } \phi_{ii} = \pi,$$

which formally amounts to a rotation depending on the mass ratios and the parity $(-1)^p$ of the permutation $p$ of $\{i,j,k\}$. Eqs. (3) and (4) lead to an important relation between harmonic polynomials in different Jacobi coordinates, i.e.

$$y_i^\lambda Y_{\lambda,\mu}(\Omega_{y_i}) = \sum_{\ell=0}^{\lambda} (-1)^\ell x_i^{\lambda-\ell} (\sin \phi_{ik})^{\lambda-\ell} y_k^{\ell} (\cos \phi_{ik})^\ell \sqrt{\frac{4\pi(2\lambda+1)!}{(2\ell+1)!(2\lambda-2\ell+1)!}} [Y^{\lambda-\ell}_\ell(\Omega_{x_k}) \otimes Y^{\ell}_\ell(\Omega_{y_k})]^{\mu,\lambda}. \quad (5)$$

Let us consider the initial three-body state $|n_0 J_0 M_0\rangle$, where $J_0$ is the total angular momentum with projection $M_0$. All the other needed quantum numbers are collected into $n_0$. The excited states $\{|n J M\rangle\}$ can be populated from the ground state by the electric multipole operator

$$O^\lambda_\mu = \sum_{i=1}^{3} z_i |r_i - R|^\lambda Y_{\lambda,\mu}(\Omega_{y_i}), \quad (6)$$

where $i$ runs over the three clusters, or equivalently, over the three sets of Jacobi coordinates.

The transition probability corresponding to this electric multipole operator is proportional to the $B(E\lambda)$-value, i.e.

$$B(E\lambda, n_0 J_0 \rightarrow n J) = \sum_{\mu M} |\langle n J M | O^\lambda_\mu | n_0 J_0 M_0 \rangle|^2 \quad (7)$$

from which the $\lambda$-multipole strengths are defined as

$$S_m = \sum_{n J} (E_{n J} - E_0)^m B(E\lambda, n_0 J_0 \rightarrow n J), \quad (8)$$

where $E_0$ is the energy of the initial state, and $E_{n J}$ is the energy of the excited state with angular momentum $J$ and additional quantum numbers $n$.

The values of these multipole strengths, depending only on the properties of the initial state, are known as the sum rules. In this work we are concentrating on the sum rules with $m=0,1$, also denoted as non-energy weighted and energy-weighted sum rules, respectively.

For the dipole case ($\lambda=1$), after inclusion of Eq. (5) into (6), and using Eqs. (2) and (4), one can see that for three particles having equal value of the ratio $z_i/m_i$ the dipole operator zero. This means that for the particular case of three identical particles all the dipole strengths $S_m$ in Eq. (8) are zero.

III. THE NON-ENERGY WEIGHTED SUM RULE

The sum over all transitions can be rewritten provided the intermediate set of quantum numbers gives a complete description of the (bound and continuum) final states, i.e. $\sum_{n J M} |n J M\rangle \langle n J M|$ = 1. We then get:

$$S_0 = \sum_{n J} B(E\lambda, n_0 J_0 \rightarrow n J) = \sum_{n J} \sum_{\mu M} \langle n_0 J_0 M_0 | O^\lambda_\mu | n J M \rangle \langle n J M | O^\lambda_\mu | n_0 J_0 M_0 \rangle = \sum_{\mu} \langle n_0 J_0 M_0 | O^\lambda_\mu | n J M \rangle \langle n J M | O^\lambda_\mu | n_0 J_0 M_0 \rangle, \quad (9)$$

which for a given multipole operator is entirely determined by the properties of the ground state $|n_0 J_0 M_0\rangle$.

The definition in Eq. (9), together with (4) and (5), permits expressing the operator $O^\lambda_\mu$ in terms of a single set of Jacobi coordinates, leading to

$$S_0 = \sum_{i,k=1}^{3} \sum_{\ell=0}^{\lambda} \sum_{\mu=-\lambda}^{\lambda} (-1)^\ell z_{ik} \sqrt{\frac{4\pi(2\lambda+1)!}{(2\ell+1)!(2\lambda-2\ell+1)!}} \langle n_0 J_0 M_0 | x_i^{\lambda-\ell} y_k^{\ell} Y^{\lambda-\ell}_\ell(\Omega_{y_k}) Y^{\ell}_\ell(\Omega_{y_k}) \rangle \langle n_0 J_0 M_0 \rangle, \quad (10)$$

where $i$ runs over the three clusters, or equivalently, over the three sets of Jacobi coordinates.
TABLE I: Non-energy weighted sum rule \((S_0)\) and the contribution of the kinetic energy operator to the energy weighted sum rule \((S_{1}^{(3)})\) for a system of three particles with equal mass \((m)\) for \(\lambda=1\). The first column gives the number \(N\) of charged particles each with charge \(z\). The symbol \(\{\}\) denotes expectation value in the initial state, and \(r_p\) is the coordinate for one of the charged particles.

| \(N\) | \(S_0\) | \(S_{1}^{(3)}\) |
|---|---|---|
| 1 | \(3z^2\langle |r_p - R|^2\rangle/(4\pi)\) | \(3z^2\frac{\lambda^2}{(4\pi m)}\) |
| 2 | \(3z^2\langle |r_p - R|^2\rangle/(4\pi)\) | \(3z^2\frac{\lambda^2}{(4\pi m)}\) |
| 3 | 0 | 0 |

where the constants

\[c_i = \sqrt{\frac{m_N(m_j + m_k)}{m_i}}\] (11)

arise when inserting (2) into the definition (10).

The summation over the indexes \(\mu\) and \(m_1\) can be made analytically [16], leading to the final expression for the non-energy weighted sum rule:

\[S_0 = \sum_{i,k=1}^{3} \sum_{\ell=0}^{\lambda} z_{i}z_{k} \left( \begin{array}{ccc} \lambda & \lambda - \ell & \ell \\ 0 & 0 & 0 \end{array} \right) \frac{2\lambda + 1}{\sqrt{2(\lambda - \ell) + 1}}\] (12)

The sum \((S_0)_{\text{diag}}\) of the diagonal terms \((i=k)\) in Eq. (12) is obtained taking \(\varphi_{ii} = \pi\) and \(\ell = \lambda\) (which reduce Eqs. 8 and 9 to identities) which leads to:

\[(S_0)_{\text{diag}} = \frac{2\lambda + 1}{4\pi} \sum_{i=1}^{3} z_i^2 \langle J_0 M_0 | |r_i - R|^{2\lambda}| J_0 M_0 \rangle .\] (13)

For a three-body system containing only one charged particle the non-energy weighted sum rule reduces to one of the three diagonal terms in Eq. (13). When more than one charged particle enter in the three-body system, the full expression [12], that contains interferences between charged particles, must be used.

The relevance of the non-diagonal terms can be easily seen for a system containing three identical particles with mass \(m\) and charge \(z\) for \(\lambda=1\). In this case the sum of the diagonal contributions \(3\frac{z^2}{4\pi} \langle |r_p - R|^2 \rangle\) given by Eq. (13) is fully canceled by the non-diagonal terms, such that \(S_0=0\), as expected for three identical particles.

When only two of the particles with mass \(m\) each have the charge \(z\), one of the diagonal terms is canceled out by the non-diagonal one, and we get \(S_0 = 3z^2 \frac{3}{4\pi} \langle |r_p - R|^2 \rangle\), which is identical to the result when only one particle is charged. These results are summarized in the second column in Table I.

### IV. THE ENERGY-WEIGHTED SUM RULE

The energy weighted sum rule is most easily obtained by evaluating the expectation value of the double commutator in the ground state, i.e.

\[S_1 = \frac{1}{2} \sum_{\mu} \langle n_0 J_0 M_0 | [O_{\mu}^{\lambda}, H], O_{\mu}^{\lambda} | n_0 J_0 M_0 \rangle = \sum_{\mu} \langle n_0 J_0 M_0 | O_{\mu}^{\lambda} H O_{\mu}^{\lambda} - E_0 O_{\mu}^{\lambda} O_{\mu}^{\lambda} | n_0 J_0 M_0 \rangle ,\] (14)

where \(E_0\) is the ground state energy.

This expression is obtained by inserting the identity operator \(1 = \sum \{nJM\} |nJM\rangle \langle nJM|\) between \(H\) and \(O_{\mu}^{\lambda}\) and between \(O_{\mu}^{\lambda}\) and \(O_{\mu}^{\lambda}\), where \(\{nJM\}\) are the complete set of eigenstates of \(H\) with the corresponding set of eigenvalues \(\{E_{nJ}\}\). In this way we immediately recover the standard definition in Eq. (6):

\[S_1 = \frac{1}{2} \sum_{nJ} (E_{nJ} - E_0) \sum_{\mu M} \langle |nJM| O_{\mu}^{\lambda} | n_0 J_0 M_0 \rangle^2 .\] (15)

According to Eq. (14) the energy-weighted sum rule depends on the multipole operator, the initial state properties, and the Hamiltonian. This Hamiltonian can have a complicated angular momentum dependence of both two- and three-body interactions, whose contributions to \(S_1\) in general do not vanish. In particular we shall assume two-body interactions that depend on the relative partial wave between the two particles, and three-body potentials depending on the total angular momentum and parity of the three-body state.

In the following subsections we evaluate the expression (14) separately for the different terms of the Hamiltonian, i.e. the traditional contribution from the kinetic energy operator, and the new terms arising from the partial wave dependent two-body potentials, and \(J^{\pi}\)-dependent three-body potentials.

#### A. Kinetic energy operator

The kinetic energy operator can be expressed in terms of any of the three sets of Jacobi coordinates as

\[T = -(\Delta_{x_k} + \Delta_{y_k})\hbar^2/2m_N ,\] (16)

where the two Laplace operators \(\Delta_{x_k}\) and \(\Delta_{y_k}\) are associated to the Jacobi coordinates \(x_k\) and \(y_k\). Since the multipole operator (6) only depends on \(y\)-coordinates we can quickly find the commutator \([O_{\mu}^{\lambda}, T]\) (Eq. (11)), from which we get:

\[\nabla_{y_k} \left( |r_k - R|^{\lambda} Y_{\lambda,\mu}^{*}(\Omega_{y_k}) \right) \cdot \nabla_{y_k} \left( |r_i - R|^{\lambda} Y_{\lambda,\mu}(\Omega_{y_i}) \right) .\] (17)
Eq. (3) permits rewriting of Eq. (17) in terms of a single set of Jacobi coordinates, leading to:

\[
[\{O^\mu_i, T\}, O^\mu_i] = \frac{\hbar^2}{mN} \sum_{i,k=1}^{3} (c_i)^3 (c_k)^3 \hat{z}_i \hat{z}_k \sum_{\ell=0}^{\lambda} \sum_{m=-\mu}^{\lambda} (-1)^{\mu} \\
\times \sqrt{2\lambda + 1} \left( \frac{\ell - \mu}{m} \right) \sqrt{\frac{4\pi (2\lambda + 1)!}{(2\ell + 1)! (2\lambda - 2\ell + 1)!}} \\
\times \nabla y_\mu (y_k Y_{\lambda,\mu}^\ell(\Omega_{y_k}) \cdot \nabla y_\mu (y_k Y_{\ell,m}^\mu(\Omega_{y_k}))) \\
\times \nabla y_\mu (y_k Y_{\lambda,\mu}^\ell(\Omega_{y_k}) \cdot \nabla y_\mu (y_k Y_{\ell,m}^\mu(\Omega_{y_k}))) \right) \ .
\]

(18)

The scalar product can now be performed by use of the Gradient Formula (A22), and after writing the two spherical harmonics in terms of a single one, and performing analytically the summations over angular momentum projection quantum numbers (details are given in the appendix), one gets the following final expression for the contribution of the kinetic energy operator to the energy-weighted sum rule \( S_1(T) \):

\[
S_1(T) = \frac{-\hbar^2}{2mN} \sum_{i,k=1}^{3} (c_i)^3 (c_k)^3 \hat{z}_i \hat{z}_k \sum_{\ell=1}^{\lambda} (\sin \varphi_{ik})^{\lambda - \ell} (\cos \varphi_{ik})^\ell \\
\times \lambda((2\ell - 1)(2\lambda + 1)!(2\lambda + 1)^{\ell - \ell} (2\ell - 2\ell + 1)!) \\
\times \nabla y_\mu (y_k Y_{\lambda,\mu}^\ell(\Omega_{y_k}) \cdot \nabla y_\mu (y_k Y_{\ell,m}^\mu(\Omega_{y_k}))) \\
\times \nabla y_\mu (y_k Y_{\lambda,\mu}^\ell(\Omega_{y_k}) \cdot \nabla y_\mu (y_k Y_{\ell,m}^\mu(\Omega_{y_k}))) \right) \ .
\]

(19)

where the sum of the diagonal parts \((i=k)\) become

\[
\left( S_1^{(T)} \right)_{\text{diag}} = \frac{\hbar^2}{2mN} \frac{\lambda(2\lambda + 1)^2}{4\pi} \\
\times \sum_{i=1}^{3} (c_i)^2 \hat{z}_i \hat{z}_i \frac{\nabla y_\mu (y_i M_0)||r_i - R||^{2\lambda - 2}}{\nabla y_\mu (y_i M_0)},
\]

(20)

where the constants \(c_i\) are given by Eq. (11).

For \(\lambda=1\) the expression in Eq. (19) is independent of the properties of the initial state. In particular, for three identical particles with mass \(m\) and charge \(z\) the total value of \(S_1^{(T)}\) is zero, which confirms the result anticipated at the end of section III. When one of these three particles has no charge, \(S_1^{(T)}\) takes a constant value which is the same as the one obtained when only one of the three particles with mass \(m\) is charged. The precise expressions of \(S_1^{(T)}\) for these particular cases are given in the last column of table III.

### B. Partial-wave dependent two-body potentials

Typically, the two-body interactions are adjusted separately for the individual partial waves in order to reproduce the known experimental data for the two-body systems. This procedure leads to two-body interactions depending on the two-body quantum numbers \(\{\ell_x, s_x, j_x\}\). The full two-body potential operator takes the form

\[
\hat{V}_{2b}^{(i)} = \sum_{i} V_{2b}^{(i)} \ ,
\]

where the index \(i\) runs over all the three sets of Jacobi coordinates and \(\hat{V}_{2b}^{(i)}\) is the two-body operator describing the interaction between particles \(j\) and \(k\). This two-body operator is formally written as:

\[
\hat{V}_{2b}^{(i)} = \sum_{\ell_x, s_x, j_x, m_x} \sum_{\ell_x, s_x, j_x, m_x} V_{2b}^{(i)}(\ell_x, s_x, j_x, m_x)|\ell_x, s_x, j_x, m_x\rangle \langle \ell_x, s_x, j_x, m_x| ,
\]

(21)

where \(\hat{P}_i\) represents any spin operator that could enter in the two-body potentials.

The contribution of the full two-body potential operator \(\hat{V}_{2b}\) to the second sum rule has then three contributions, each corresponding to one of the three two-body interactions. According to Eq. (11), the contribution \(S_{12b,1}^{(2b,i)}\) \((i=1,2,3)\) from each of them is given by:

\[
S_{12b,1}^{(2b,i)} = \sum_{\mu} \left[ (n_0 J_0 M_0 |O_1^\mu \hat{V}_{2b}^{(i)} O_1^\mu |n_0 J_0 M_0) \\
- (n_0 J_0 M_0 |O_1^\mu \hat{V}_{2b}^{(i)} |n_0 J_0 M_0) \right] ,
\]

(22)

where \(|n_0 J_0 M_0\rangle\) represents the initial state with total angular momentum \(J_0\) and projection \(M_0\). The quantum number \(n_0\) refers to all other additional quantum numbers necessary to specify this state.

For each two-body interaction \(V_{2b}^{(i)}\) it is now convenient to write the corresponding ground state wave function \(\Psi\) in terms of the Jacobi coordinates \(\{x_i, y_i\} \equiv \{\rho, \alpha_i, \Omega_x, \Omega_y\}\), and expand it in terms of a set of functions \(\gamma_i \gamma_0 \gamma_0 (\Omega_i)\):

\[
\Psi_{\gamma_0 \gamma_0 \gamma_0}(x_i, y_i) = \frac{1}{\rho^{\gamma_i}} \sum_{\gamma_i} F_{\gamma_i}^{n_0 J_0}(\rho) \gamma_i \gamma_0 \gamma_0 (\Omega_i),
\]

(23)

where

\[
\gamma_i \gamma_0 \gamma_0 (\Omega_i) = \phi_{K}^{(\ell_x, s_x, j_x)}(\alpha_i) |\ell_x, s_x, j_x\rangle \otimes |\ell_y, s_y, j_y\rangle \\
\gamma_0 \gamma_0 (\Omega_i) \gamma_0 (\Omega_i)
\]

(24)

with \(\gamma_i \equiv \{K, \ell_x, s_x, j_x, \ell_y, s_y, j_y\}\), and with \(\phi_{K}^{(\ell_x, s_x, j_x)}(\alpha_i)\) being the usual function of the hyperangle \(\alpha_i\) entering in the definition of the hyperspherical harmonics (13). The functions (24) reduce to the usual hyperspherical harmonics for particles without spin.

With the definition (21), the two-body potential operator \(\hat{V}_{2b}^{(i)}\) acting on a term of the basis \(\gamma_i \gamma_0 \gamma_0 (\Omega_i)\) (written in the Jacobi set \(i\)) leads to

\[
\hat{V}_{2b}^{(i)} \gamma_i \gamma_0 \gamma_0 (\Omega_i) = V_i^{(\ell_x, s_x, j_x)}(x_i) \hat{P}_i \gamma_i \gamma_0 \gamma_0 (\Omega_i)
\]

(25)

Eq (23) permits to write Eq. (22) as:

\[
S_{12b,1}^{(2b,i)} = \sum_{\mu} \int d\rho \sum_{\gamma_i} F_{\gamma_i}^{n_0 J_0}(\rho) F_{\gamma_i}^{n_0 J_0}(\rho)
\]

(26)

\[
\left[ \langle \gamma_i \gamma_0 \gamma_0 |O_1^\mu \hat{V}_{2b}^{(i)} O_1^\mu |\gamma_i \gamma_0 \gamma_0 \rangle - \langle \gamma_i \gamma_0 \gamma_0 |O_1^\mu \hat{V}_{2b}^{(i)} |\gamma_i \gamma_0 \gamma_0 \rangle \right]
\]
Inserting in the first and second matrix elements the unity operator
\[ 1 = \sum_{\gamma_i} \sum_{J'M''} \langle Y_{\gamma_i}^{J'M''} (\Omega_i) \rangle \langle Y_{\gamma_i}^{J'M''} (\Omega_i) \rangle, \]
(27)
then be written for this particular case as:
\[ S^{(2b, i)}_1 = \sum_{\mu} \int d\rho \sum_{\gamma_i} F^{n_0 J_0}_\mu (\rho) F^{n_0 J_0}_\mu (\rho) \frac{\langle Y_{\gamma_i}^{J'M''} (\Omega_i) \rangle}{\langle Y_{\gamma_i}^{J'M''} (\Omega_i) \rangle} \]
\[ \sum_{\gamma_i} \sum_{J'M''} \langle Y_{\gamma_i}^{J'M''} (\Omega_i) \rangle \langle Y_{\gamma_i}^{J'M''} (\Omega_i) \rangle \]
\[ \langle Y_{\gamma_i}^{J'M''} (\Omega_i) \rangle \left( V_i \left( \ell_{x_i}, s_{x_i}, j_{x_i} \right) (x_i) \tilde{P}_{\mu} \right) O_{\mu} \]
\[ -V_i \left( \ell_{x_i}, s_{x_i}, j_{x_i} \right) (x_i) O_{\mu} \left( \tilde{P}_{\mu} \right) \langle Y_{\gamma_i}^{J'M''} (\Omega_i) \rangle. \]
(28)

When the \( V_i \) functions are independent of the partial wave, the equation above can be written in a more compact way as:
\[ S^{(2b, i)}_1 = \sum_{\mu} \sum_{\gamma_i} \int d\rho F^{n_0 J_0}_\mu (\rho) F^{n_0 J_0}_\mu (\rho) \]
\[ \langle Y_{\gamma_i}^{J'M''} (\Omega_i) \rangle \left( V_i \left( \ell_{x_i}, s_{x_i}, j_{x_i} \right) (x_i) \tilde{P}_{\mu} \right) O_{\mu} \]
\[ \langle Y_{\gamma_i}^{J'M''} (\Omega_i) \rangle \left( V_i \left( \ell_{x_i}, s_{x_i}, j_{x_i} \right) (x_i) \tilde{P}_{\mu} \right) O_{\mu} \]
\[ \langle Y_{\gamma_i}^{J'M''} (\Omega_i) \rangle \]
which is trivially zero for the central part of the two-body potential \((P_1 = 1)\), and for the spin-spin term \((O_\mu^A\) does not depend on the spin and therefore commutes with the spin-sporator). The same happens for the tensor operator, which depends only on coordinates and spin operators. For the spin-orbit term \((\ell \cdot s \cdot x = \ell_x s_x \cdot \ell_s + \ell_s s_x + \ell_x s_x)\) one has the same result, since \(\ell_x, \ell_s, \) or \(\ell_x\) applied on \(\mu^A\) is proportional to either \(O_{\mu+1}^A\), \(O_{\mu-1}^A\), or \(O_{\mu}^A\), and therefore each of the three terms in \(\ell_x \cdot s_x\) double commutes with \(O_{\mu}^A\).

Thus, for two-body interactions independent of the partial waves and containing the usual spin operators one has \(S^{(2b)}_1 = 0\).

If the two-body potentials are partial wave dependent, but contain only central, spin-spin \((P_1 = s \cdot s)\) and spin-orbit \((P_2 = \ell_x \cdot s_x)\) terms, since these operators are diagonal in the basis \(\{ |\ell_x, s_x, j_x, m_x \rangle \}\), one then has:
\[ \tilde{P}_{\mu} \langle Y_{\gamma_i}^{J'M''} (\Omega_i) \rangle = f_{j_{x_i}, s_{x_i}}^{j_{x_i}, s_{x_i}} \langle Y_{\gamma_i}^{J'M''} (\Omega_i) \rangle \]
(30)
where \(f_{j_{x_i}, s_{x_i}}^{j_{x_i}, s_{x_i}} = 1\) for the central part of the potential, \(f_{j_{x_i}, s_{x_i}}^{j_{x_i}, s_{x_i}} = (s_x(j_x + 1) - s_j(s_j + 1) - s_k(s_k + 1))/2\) for the spin-part part, and \(f_{j_{x_i}, s_{x_i}}^{j_{x_i}, s_{x_i}} = (j_x(j_x + 1) - \ell_x(\ell_x + 1) - s_x(s_x + 1))/2\) for the spin-orbit part. Eq. (28) can have three terms (see Eq. (9)), each expressed in one of the three sets of Jacobi coordinates. When inserted in Eq. (31), the two terms in \(O_{\mu}^A\) differing from the set of Jacobi coordinates \(i\) must be transformed into this set by use of Eq. (5).

When only one of the three particles is charged the operator \(O_{\mu}^A\) reduces to one term. A partial wave dependence in the interaction between the charged particle and any of the other two will produce a non-vanishing contribution to the energy-weighted sum rule according to Eq. (51). However, if the only partial wave dependence appears in the two-body potential between the two neutral particles then \(S^{(2b)}_1 = 0\). This is because the \(O_{\mu}^A\) operator then automatically is written in the same Jacobi set as the angular functions in Eq. (51). The operator is then independent of \(\Omega_{s_i}\), and the integral over these angles in the last matrix element of (31) vanishes unless \(\ell''_x = \ell'_x, s''_x = s'_x, j''_x = j'_x,\) and therefore the full matrix element vanishes.

The integrals over \(\Omega_{s_i}\) and \(\Omega_{p_i}\) in the two matrix elements that appear in Eq. (51) can be calculated analytically, because \(s = p \sin \alpha_i\), and therefore the two-body potentials are independent of the angles \(\Omega_{s_i}\) and \(\Omega_{p_i}\). The expressions for these two matrix elements are given as Eq. (A6) of the appendix for the particular case of particles without spin.

As an example we consider dipole excitations \((\lambda = 1)\) in a system of three spin zero particles with equal mass \(m = 4m_N\), where \(m_N\) is the nucleon mass, and where two particles are neutral and one particle has a charge equal to twice the proton charge. We consider only \(s\) and \(p\) waves in the calculation. The two-body interactions are taken to be gaussians \((V_s,p(r) = W_s,p e^{-r^2/b^2})\) with equal range \(b\) for \(s\) and \(p\) waves. We have constructed a \(0^+\) ground state with a very large contribution of \(s\)-waves, and a few percent of \(p\)-waves. This has been done by taking \(b = 2.98\) fm, \(W_s = W_p = -0.18\) MeV for the interaction between the two neutral particles, and \(W_s = W_p = -1.18\) MeV for the interaction between the charged particle and one of the neutral ones. The binding energy of the \(0^+\) state is \(-10.38\) MeV. According to Eq. (51), since only terms with \(j''_x \neq \ell''_x\) contribute \((s''_x = s'_x = 0, j''_x = j'_x = \ell'_x, j''_x = \ell''_x, j''_x = \ell''_x)\), the contribution \(S^{(2b)}_1\) to the energy-weighted sum rule is pro-
usual to employ effective three-body forces to fine tune the energies of the computed states. Very often different three-body forces are used to place the lowest state with given angular momentum and parity $J^\pi$ at the correct energy. This means that these three-body potentials usually depend on $J^\pi$. In this subsection we investigate the additional contribution $S_1^{(3b)}$ to the energy-weighted sum rule arising from this kind of three-body potentials. With these assumptions the three-body potential operator can be written as:

$$V_{3b} = \sum_{J^\pi M} \sum_{n_{(J^\pi)}} \left[ \langle n_0 J_0^\pi M_0 | O_\mu \hat{V}_{3b} O_\mu | n_0 J_0^\pi M_0 \rangle - \langle n_0 J_0^\pi M_0 | O_\mu \hat{V}_{3b} O_\mu | n_0 J_0^\pi M_0 \rangle \right],$$

where $n_{(J^\pi)}$ refers to all the additional quantum numbers needed to specify each of the three-body states with total angular momentum and parity $J^\pi$. Following Eq. (12) we can write:

$$S_1^{(3b)} = \sum_\mu \left[ \langle n_0 J_0^\pi M_0 | O_\mu \hat{V}_{3b} O_\mu | n_0 J_0^\pi M_0 \rangle - \langle n_0 J_0^\pi M_0 | O_\mu \hat{V}_{3b} O_\mu | n_0 J_0^\pi M_0 \rangle \right],$$

which gives the contribution to the energy-weighted sum rule from $J^\pi$-dependent three-body potentials. This contribution vanishes when the three-body interactions are $J^\pi$-independent.

For the special case in which the ground state has $J_0 = 0$ the expression simplifies to:

$$S_1^{(3b)} = \sum_\mu \langle n_0 J_0^\pi M_0 | O_\mu \hat{V}_{3b} \hat{V}_{3b} O_\mu | n_0 J_0^\pi M_0 \rangle.$$

Once the analytic expression of $S_1^{(3b)}$ for $J_0=0$ is given by Eq. (12), but with an additional factor equal to the difference between the three-body potentials inserted in the last matrix element.

In Fig. 1 the dashed line (with circles) shows $S_1^{(3b)}$ for the same system and the same transition as for the $S_1^{(2b)}$ case. We have taken the $\ell$-independent two-body potentials used in subsection [19] as starting point, meaning that $S_1^{(3b)} = S_1^{(1b)}$. The result is shown as a function of the strength difference ($\Delta W$) between the gaussian effective three-body forces used to compute the $1^-$ excited states and the $0^+$ ground state. The range of the three-body force is the same (6.0 fm) for $0^+$ and $1^-$. The variation in $\Delta W$ is obtained by changing the strength proportional to $\Delta W = W_s - W_p$, where $W_s$ and $W_p$ refer to the strengths of the interactions between the charged and the neutral particle.

In Fig. 1 the dashed line (+ signs) shows $S_1^{(2b)}$ as a function of $\Delta W$ when the strength of the $s$-wave potential between the charged and neutral particles ($W_s$) is kept fixed and $W_p$ is changed. Since the $p$-wave contribution to the ground state wave function is insignificant, a small variation in the strength of the $p$-wave potential only slightly modifies the ground state radial wave functions $F_{L^\pi J^\pi}(\rho)$. Therefore, the behaviour of $S_1^{(2b)}$ is almost perfectly linear with $\Delta W$. However, if we modify $\Delta W$ by keeping $W_p$ fixed while changing $W_s$, the radial wave functions are much more sensitive to a change in the $s$-wave two-body potential, since the $s$-waves dominate. Therefore $S_1^{(2b)}$ is not a completely linear function of $\Delta W$ as seen by the solid line (-× signs-- in the figure). When $\Delta W=0$, the total value of $S_1$ for this particular case is $S_1=9.90$ e² MeV fm², which means that the contribution from $\Delta W \neq 0$ can be of comparable size, see Fig. 1.

### C. $J^\pi$-dependent three-body potentials

When performing three-body calculations it is quite usual to employ effective three-body forces to fine tune...
in the three-body force for the $1^-$ excited states. Then
the ground state wave function remains unchanged. As a
consequence, according to Eq. (34), and as demonstrated
by the dotted line in the figure, $S_1^{(3b)}$ depends linearly
on $\Delta W$. The contribution from $S_1^{(3b)}$ can be of compar-
able size to the value, $S_1 = 9.90 \, e^2 \text{MeV fm}^2$, for angular
momentum independent potentials.

V. A REALISTIC CASE: DIPOLE EXCITATIONS IN $^6\text{He}$

The main properties of the borromean two-neutron halo nuclei are well reproduced describing them as three-
bodies systems made by an inert core surrounded by two
neutrons. The characteristic feature of these nuclei is
their large spatial extension, which is responsible for the
large values of the breakup cross sections after electromagnetic excitation. This can be easily envisaged from
Eqs. (13) and (20), which depend directly on the size of
the system. For this reason, electromagnetic excitations
of two-neutron halo nuclei have attracted a lot of atten-
tion, specially dipole excitations, which is the dominating
role in this section we investigate dipole excitations in $^6\text{He}$
($\alpha+n+n$), which is one of the most prominent exam-
plars of borromean two-neutron halo nuclei. We com-
pute the three-body states by use of the hyperspheric adiabatic expansion method [13]. The neutron-neutron
and $\alpha$-neutron interactions are the ones used for instance in
[17]. The computed bound ground state ($0^+$) has a
two-neutron separation energy matching the experimen-
tal value of $-0.97 \pm 0.04$ MeV. This is achieved with
a gaussian effective three-body force with range 2.9 fm
and strength $-7.55$ MeV. The continuum $1^-$ states have
been discretized by use of a box boundary condition at
$\rho_{\text{max}} = 50$ fm.

A. Dipole strength function

The transition probability $B$ from the ground state to
one of the box discretized continuum states is given in
Eq. (7). To obtain a smooth distribution from the dis-
etrized continuum we use the finite energy interval app-
proximation to the strength function,

$$\frac{dB}{dE} \approx \frac{\Delta B}{\Delta E},$$

where $\Delta E$ is the size of the given energy interval, and $\Delta B$ is the sum of the transition probabilities into the states
whose energies fall into this interval. These values are
then plotted as function of the central energy values of
the intervals.

The interval should be of a reasonable size, i.e. large
enough to provide a smooth function but small enough
to wash out the desired structure. In practice we
have used bins with centers at 0.3, 0.9, 1.5, 2.3, 3.2, 4.2,
5.4, 6.7, and 8.2 MeV, and a standard cubic interpolation
to smooth the curve.

In Fig. 2 we compare with the measured distribution
[18] the computed smoothed dipole strength function for
$^6\text{He}$ for different gaussian three-body potentials in the
excited $1^-$ states. A strongly attractive three-body po-
tential produces a pronounced low-lying peak which for
even stronger attraction would turn into a bound state.
Thus the three-body potential should at least be less attrac-
tive than that corresponding to $W_{3b}^{(1^-)} = -40$ MeV
($b=2.9$ fm). For moderately attractive three-body po-
tentials we observe an increase from zero at threshold to
a peak value at around 1 MeV followed by a relatively
fast decrease towards zero at higher energies. This is
consistent with the calculations in [8] and [19]. Com-
pared to the experiment [18], the theory overestimates the
strength at around 1 MeV and consistent with the
sum rule underestimate the strength at higher energies.
Apparently a significant three-body repulsion in the $1^-$
channel would approach the experimental data presented with relatively large error bars.

B. Sum rule results

The second and third columns of table [11] give the non-
ergy weighted ($S_0$) and energy-weighted ($S_1$) dipole
sum rule strengths. The experimental data, available from
[18], are given in the first and third rows including
states of energies below 5 MeV and 10 MeV, respectively.
The corresponding theoretical values are ob-
Experimental data are from [18]. The energies of 5 MeV and 10 MeV, respectively. The last row gives the converged results including all excitations. The experimental data are from [18]. The \( S_0 \) values are given in units of \( e^2 \text{ fm}^2 \) and \( S_1 \) and \( S_1^{(T)} \) are in units of \( e^2 \text{ fm}^2 \text{ MeV} \). The average dipole resonance energy \( S_1/S_0 \) is given in MeV.

| \( E^* \leq 5 \text{ MeV (exper.)} \) | \( S_0 \) | \( S_1 \) | \( S_1^{(T)} \) | \( S_1/S_0 \) |
|---------------------------------|--------|--------|--------|--------|
| 0.59±0.12 1.9±0.4              | 3.22±0.94 |
| \( E^* \leq 5 \text{ MeV (theor.)} \) | 0.66   | 1.94   | 2.94   |
| \( E^* \leq 10 \text{ MeV (exper.)} \) | 1.2±0.2 | 6.4±1.3 | 5.3±1.4 |
| \( E^* \leq 10 \text{ MeV (theor.)} \) | 1.01   | 4.43   | 4.39   |
| Converged                        | 1.25   | 8.26   | 4.95   | 6.61   |

We can see that the computed results for \( S_0 \) agree very well with the experimental values when the sum over the excited states in Eq. (14) is restricted to energies below 5 MeV and 10 MeV, respectively. As even higher energies are included the value of \( S_0 \) converges to the result given in the last row of the table, which agrees with the expected result obtained from Eq. (13). The converged value is already reached with an energy limit of about 40 MeV.

Essentially the same happens for \( S_1 \). The computed values agree reasonably well with the experimental ones. Also the result obtained for energies below 10 MeV is still clearly below the converged value, which requires integration up to energies at least of about 60 MeV. The converged value for \( S_1 \) clearly disagrees with the result provided by Eq. (20), where only the kinetic energy contribution to the \( S_0 \) values are given in Table II. The converged value can change significantly with the energy limit of about 40 MeV.

In any case these rather large variations illustrate how important it is in practice to use the correct sum rules in such estimates.

So far all the calculations of the \( S_1 \) strength have been performed with the same effective three-body force for the ground state and the \( 1^- \) excited states. For the \( 1^- \) states, the interaction might be different and an additional contribution to the \( S_1 \) strength would appear as seen in Eq. (15).

In Fig. 3 we show the dipole sum rule strength \( S_1 \) for \( ^6\text{He} \) as a function of the maximum energy allowed above threshold. Gaussian three-body forces are used to obtain the ground \((0^+)\) and excited \((1^-)\) three-body states. The range of the gaussian is the same (2.9 fm) for all the states. The different curves show the results obtained with different values of the strength \((W_{3b}^{(1-)}\) of the three-body force for the \( 1^- \) states. The thick curve is the result with the same three-body force for the ground and excited states. The experimental data are from [18].

The thin solid lines in the figure show the dipole sum rule strength \( S_1 \) for \(^6\text{He}\) as a function of the maximum energy allowed above threshold. We have considered gaussian three-body forces with a range of 2.9 fm. For the ground state \((0^+)\) a strength of \(-7.55\text{ MeV}\) has been used. When the excited states are obtained with the same three-body force, \( S_1 \) behaves as shown by the thick solid line in the figure. This calculation corresponds to the numbers quoted in Table II. When the strength of the three-body force used for the \( 1^- \) states is changed, \( S_1^{(3b)} \) depends linearly on the strength difference.

The thin solid lines in the figure show \( S_1 \) for different values of the strength \((W_{3b}^{(1-)}\) of the three-body force for the \( 1^- \) states. This strength has been changed from 0 up to \(-40\text{ MeV}\), which is at the limit of producing a low-lying narrow \( 1^- \)-resonance in \(^6\text{He}\) (understood as a pole of the \( S \)-matrix). As seen in the figure, the deeper the three-body potential, the smaller the value of \( S_1 \). The converged value can change significantly with the three-body force. The result obtained with a strength of \(-40\text{ MeV}\) is about 33\% smaller than obtained for...
the experimental value. This tendency is consistent with a strength weaker than about −40 MeV.

As seen in the figure, all the curves agree well with the experimental value obtained for states below a maximum energy of 5 MeV. When this maximum energy is 10 MeV, all the computed curves are below the experiment. Although this experimental value has a rather large error bar, it is clear from the figure that the smaller strengths in the three-body force for the 1− states are closer to the experimental value. This tendency is consistent with the fact that a 1−-resonance has not been found experimentally since a strength weaker than about −30 MeV also excludes such a state in computations. Extension to include higher energies in the experiment would allow distinction between the values obtained for different strengths. Probably 6He is a very favorable system for this investigation because the core excitations are expected to be negligible.

VI. SUMMARY AND CONCLUSIONS

We have derived general expressions for the non-energy and energy-weighted cluster sum rules for excitations of three-body systems. We consider transitions arising due to electric multipole operators of any order and each of the constituent particles (clusters) may have a finite charge. The most obvious nuclear applications are in systems close to three-body thresholds where three-body clusterization frequently seems to be a dominating part of the structure. This is also the region where the spatially extended and weakly bound halos appear.

Accurate calculations of three-body wave functions require in general decomposition into Faddeev components either by directly solving the Faddeev equations or by a variational procedure including similar components expressed in the different Jacobi coordinates. Derivation of the non-energy weighted sum rule only relies on the use of a complete set of intermediate wave functions. Therefore only matrix elements of the multipole operators enter into the expressions whereas the interactions disappear altogether, except of course indirectly through the properties of the excited continuum states. However, the properties of the wave functions are essential and in particular the different Faddeev components give rise to crucial interference effects when more than one particle carry a charge.

Such interference effects are also crucial for the energy-weighted sum rule where in addition also the properties of the interactions are essential. This sum rule is traditionally derived as a double commutator between the hamiltonian and two multipole operators. Usually then only the second order derivatives from the kinetic energy operator contribute while the potentials including the spin-orbit terms commute with the multipole operators and lead to vanishing contributions. However, when the interactions are angular momentum dependent, the double commutator does not vanish because the multipole operators themselves also carry angular momentum. These contributions must therefore be computed and included in the sum rule estimates. Still the character of sum rule remains in the sense that no matter how the excitations are distributed, they must add up to the value given by the sum rule which only depends on properties of the ground state and the interactions.

The angular momentum dependence and the subsequent contributions to the sum rule are separated into terms arising from the two- and three-body potentials which often in accurate three-body computations depend on angular momentum. A possible sequence to determine appropriate potentials could be first to adjust the two-body potentials independently for each partial wave to known two-body bound or continuum properties. Second to fine-tune the three-body state computed with the two-body potentials to a desired energy by adding a short-range three-body potential with as little structure as possible in order to maintain the properties provided by the two-body interactions. Both types of angular momentum dependence are important as they turn out to give substantial contributions to the ordinary kinetic energy contribution to the sum rule.

To assess numerically the relative importance of these new sum rule contributions we investigate the electric dipole excitations of the ground state of the well known halo nucleus 6He. We first notice that the strength distribution has a peak at around 1 MeV, falls off at higher energies and in practice reaches zero at about 60 MeV. The contribution to the energy weighted sum rule from the two-body potentials amounts to 2/3 of the kinetic energy contribution.

The contribution from the three-body potential depends on an expectation value of the difference between those potentials for ground and excited state angular momenta of 0 and 1, respectively. Thus for state independent but finite three-body potentials we arrive at the established result of zero contribution. However, the sensitivity to the difference in these three-body potentials is significant. Realistic potentials give estimates of up to 30% of the kinetic energy value. This is then also an estimate of the sensitivity of the soft dipole mode to the three-body potential.

In conclusion, we have generalized the energy weighted and non-energy weighted cluster sum rules for electric multipole transitions to angular momentum two- and three-body interactions. The additional contributions can be comparable in size to the ordinary terms arising from the kinetic energy operator.

APPENDIX A: INTERMEDIATE EXPRESSIONS AND FORMULAS

In this appendix we give some of the intermediate expressions obtained when deriving Eq.(19).

The commutator between the electric multipole operator $O_{\mu}^{\lambda}$ and the kinetic energy operator $T$ can be written as:

$$[O_{\mu}^{\lambda}, T] = -\sum_{k=1}^{3} \frac{\hbar^2}{2m_N} \left[ |\mathbf{r}_k - \mathbf{R}|^3 Y_{\lambda,\mu}^{*}(\Omega_{y_k}), \Delta y_k \right]$$

$$= \sum_{k=1}^{3} \frac{\hbar^2}{m_N} \nabla y_k \left( |\mathbf{r}_k - \mathbf{R}|^3 Y_{\lambda,\mu}^{*}(\Omega_{y_k}) \right) \cdot \nabla y_k, \quad (A1)$$

where we have used that $\Delta y(r_{ij}Y_{\ell,\mu}(\Omega_k))=0$.

The scalar product in Eq.(19) can be made by use of the gradient formula. A derivation of this formula can be found for instance in chapter 5 of [22], from which one has

$$\nabla(\phi(r) Y_{m}(\Omega)) =$$

$$-\left( \frac{\ell + 1}{2\ell + 1} \right)^{1/2} \left( \frac{d}{dr} - \frac{\ell}{r} \right) \phi(r) Y_{\ell+1,m}(\Omega) +$$

$$\left( \frac{\ell}{2\ell + 1} \right)^{1/2} \left( \frac{d}{dr} + \frac{\ell}{r} \right) \phi(r) Y_{\ell-1,m}(\Omega), \quad (A2)$$

where

$$Y_{j,\ell,m}(\Omega) = \sum_{m,q} Y_{\ell,m}(\Omega) \delta(\ell, m; 1, q; j, m) e_q$$

(A3)

with $e_0 = e_z$, and $e_{\pm 1} = \mp(e_z \pm ie_y)/\sqrt{2}$.

Use of this expression permits to rewrite Eq.(18) as:

$$[O_{\mu}^{\lambda}, T] = \frac{\hbar^2}{m_N} \sum_{k=1}^{3} (c_k)^3 (c_k)^\lambda z_k z_\ell \sum_{\ell=1, m, n} \sqrt{2\lambda + 1}$$

$$\left( \frac{\ell}{m} - \frac{n}{n} - \mu \right) \left( \left( 2\ell + 1 \right)! \right)^{1/2} \left( 2\ell + 1 \right)!$$

$$x_{\ell-\mu}^{(\lambda)} Y_{\lambda-\mu,\ell-\mu}(\Omega_{x_k})(\sin \varphi_{x_k})^{\lambda-\ell}(\cos \varphi_{x_k})^{\lambda+\ell-2}$$

$$\left( 2\lambda + 1 \right)! \left( 2\ell + 1 \right)!$$

$$\sum_{q}\sum_{\nu} (-1)^{\lambda-\mu+\ell+m} \left( \frac{\ell - 1}{q} \frac{1}{\nu} \frac{1}{\ell} \right) \left( \lambda - 1 \right)^2 \left( \lambda - 1 \right) \left( \lambda - 1 \right)$$

Writing now the two spherical harmonics in terms of a single one, and summing up three of the 3-j symbols one gets:

$$[[O_{\mu}^{\lambda}, T], O_{\mu}^{\lambda}] = \frac{\hbar^2}{m_N} \sum_{k=1}^{3} (c_k)^3 (c_k)^\lambda z_k z_\ell \sum_{\ell=1, m, n} \sqrt{2\lambda + 1}$$

$$\left( \ell - \ell \lambda - \ell \lambda \right) \left( \frac{\ell - 1}{m} - \frac{\ell - 1}{n} - \mu \right) \frac{(2\lambda + 1)!}{\left( 2\ell + 1 \right)!\left( 2\ell - 2 \right)!}$$

$$\sum_{\lambda} (-1)^{\lambda-\ell-m+\ell} (\sin \varphi_{x_k})^{\lambda-\ell}(\cos \varphi_{x_k})^{\lambda+\ell-2}$$

$\mathbf{S_1}^{(T)}$

We close the appendix giving analytical expressions for the two matrix elements entering in Eq.(21) for the particular case of particles without spin. The expressions are obtained performing analytically the integrals over $\Omega_x$, and $\Omega_y$:

$$\langle Y_{j_{z_i},\ell_i,m_i}(\Omega_i)|O_{\mu}^{\lambda}|\Lambda_{j_{z_i},\ell_i,m_i}(\Omega_i) \rangle = (-1)^{\mu + \ell_0 + \ell_0 + \ell'' - \ell''}$$

$$\sqrt{2(\ell + 1)(\ell + 1)}$$

$$\sum_{\ell'=0}^{2\lambda + 1}(\ell'' + 1)(\ell'' + 1)(\ell'' + 1)(\ell'' + 1)(\ell'' + 1)(\ell'' + 1)$$

$$\sum_{\ell''=0}^{2\lambda + 1}(\ell'' + 1)(\ell'' + 1)(\ell'' + 1)(\ell'' + 1)(\ell'' + 1)(\ell'' + 1)$$

$$\rho^3 \sum_{k=1}^{3} z_k (c_k)^3 \int_{0}^{\pi/2} d\alpha_1 (\sin \alpha_1)^{\ell''} (\cos \alpha_1)^{\ell''} (\sin \alpha_1)^{\ell''} (\cos \alpha_1)^{\ell''}$$

$$\rho^3 \sum_{k=1}^{3} z_k (c_k)^3 \int_{0}^{\pi/2} d\alpha_1 (\sin \alpha_1)^{\ell''} (\cos \alpha_1)^{\ell''} (\sin \alpha_1)^{\ell''} (\cos \alpha_1)^{\ell''}$$

where $N_{K}\ell_s^{\lambda}\ell''$ is the normalization constant of the hyperspherical harmonic $Y_{K}^{\lambda \ell''}(\Omega)$, whose precise form can be found for instance in [13].

The expression for the second matrix element in Eq.(21) is identical to Eq.(20) but with the function $V_{\ell_0}^{(\ell_0)}(\rho \sin \alpha) - V_{\ell_0}^{(\ell_0)}(\rho \sin \alpha)$ included as a factor in the integrand, and with primes on the quantum numbers $K$, $\ell_0$, and $\ell''$.
