Fig. S1. Expression of bone formation markers in induced SHP-2-deficient mice. Littermate shp-2 fl/fl ert2-cre and shp-2 fl/fl control mice were injected with tamoxifen at 6 wk of age. Either 1 or 7 wk later, femora and tibia were obtained from mice and flushed free of bone marrow. RNA was prepared from crushed bones using Trizol reagent (Invitrogen) and expression of the indicated bone formation markers was assessed by quantitative RT-PCR using established primer/probe pairs (Applied Biosystems). Results for each marker were normalized to expression of levels of GAPDH in each sample and data are presented as fold change in mRNA expression in shp-2 fl/fl ert2-cre bone compared to corresponding littermate shp-2 fl/fl bone. Values greater than 1 indicate increased mRNA expression. Akp2, alkaline phosphatase 2; Ibsp, integrin-binding sialoprotein; Runx-2, Runt-related transcription factor-2.
