SMALE SPACES WITH VIRTUALLY NILPOTENT SPLITTING

VOLODYMYR NEKRASHEVYCH

ABSTRACT. We show that if $(X, f)$ is a locally connected Smale space such that the local product structure on $X$ can be lifted by a covering with virtually nilpotent group of deck transformations to a global direct product, then $(X, f)$ is topologically conjugate to a hyperbolic infra-nilmanifold automorphism. We use this result to give a generalization to Smale spaces of a theorem of M. Brin and A. Manning on Anosov diffeomorphisms with pinched spectrum, and to show that every locally connected codimension one Smale space is topologically conjugate to a hyperbolic automorphism of a torus.

1. Introduction

Smale spaces were introduced by D. Ruelle (see [Rue78]) as generalizations of basic sets of Axiom-A diffeomorphisms. They were also extensively studied before as "spaces with hyperbolic canonical coordinates" by R. Bowen [Bow70, Bow71].

A Smale space is a compact metric space \( X \) with a homeomorphism \( f : X \to X \) such that there exists a local direct product structure on \( X \) with respect to which \( f \) is expanding in one and contracting in the other direction. For example, every Anosov diffeomorphism is a Smale space.

Smale spaces are classical objects of the theory of dynamical systems, but many basic questions about them (and even about Anosov diffeomorphisms) remain to be open.

For example, it seems that the following question is open.

**Question 1.** Is it true that if \((X, f)\) is a Smale space such that \(X\) is connected and locally connected, then \((X, f)\) is topologically conjugate to an Anosov diffeomorphism?

Many well studied examples of Smale spaces are such that one of the factors of the local direct product structure is totally disconnected, e.g., the Smale solenoid (see [BS02, Section 1.9]). See more examples in [Wil74, AP98]. See also [Wie12], where it is proved that all such Smale spaces are inverse limits of iterations of one self-map, i.e., are natural generalizations of solenoids.

Note that a question similar to Question 1 for expanding maps has a positive answer. Namely, the following theorem follows from Gromov’s theorem on groups of polynomial growth [Gro81], [Nek05, Theorem 6.1.6], [Nek08, Theorem 5.9].

**Theorem 1.1.** Let \( f : X \to X \) be a self-covering map of a locally connected and connected compact metric space. Suppose that there exists a covering map \( \pi : \tilde{X} \to X \) such that \( f \) can be lifted by \( \pi \) to an expanding homeomorphism of \( \tilde{X} \). (This is true, for example, if \( f : X \to X \) is locally expanding and \( X \) is semi-locally simply connected.) Then \((X, f)\) is topologically conjugate to an expanding infra-nilmanifold endomorphism.

Here an *infra-nilmanifold endomorphism* is a map \( \phi : G\backslash L \to G\backslash L \), where \( L \) is a simply connected nilpotent Lie group, \( G \) is a subgroup of the affine group \( \text{Aut}(L) \times L \) acting on \( L \) freely, properly, and co-compactly, and \( \phi \) is induced by an automorphism \( \Phi : L \to L \). If the automorphism \( \Phi \) is expanding, i.e., if all eigenvalues of \( D\Phi \) have absolute value greater than one, then we say that the corresponding endomorphism \( \phi \) is expanding. If \( D\Phi \) has no eigenvalues of absolute value one, then we say that \( \phi \) is *hyperbolic*.

Note, that the case when \( f : X \to X \) in Theorem 1.1 is an expanding endomorphism of a Riemannian manifold, is a result of M. Gromov [Gro81] (based on results of M. Shub [Shu70]).

All known examples of Anosov diffeomorphisms, and hence apparently all known examples of locally connected Smale spaces are hyperbolic automorphisms of infra-nilmanifolds. See [Sma67], and Problem 3 in the additional list of problems in [Sma00]. It was proved by A. Manning in [Man74] that every Anosov diffeomorphism of an infra-nilmanifold is topologically conjugate to a hyperbolic automorphism of an infra-nilmanifold. Another result in this direction is a theorem of J. Franks [Fra70] stating that if \((X, f)\) is an Anosov diffeomorphism such that stable or unstable
manifolds of $X$ are one-dimensional, then $(X, f)$ is topologically conjugate to a hyperbolic linear automorphism of the torus $\mathbb{R}^n/\mathbb{Z}^n$.

One of the main difficulties of proving that every Anosov diffeomorphism is an automorphism of an infra-nilmanifold is showing that the foliations of $X$ into stable and unstable manifolds when lifted to the universal covering $\tilde{X}$ of $X$ come from a direct product decomposition of $\tilde{X}$.

**Definition 1.1.** We say that a Smale space $(X, f)$ is splittable if there exists a covering map $\pi : M \rightarrow X$ and a direct product decomposition $M = A \times B$ of $M$ such that $\pi$ maps plaques $\{a\} \times B$ and $A \times \{b\}$ of the direct product decomposition of $M$ bijectively to stable and unstable leaves of $X$.

Here a stable (resp. unstable) leaf of $X$ is the equivalence class with respect to the equivalence relation $\lim_{n \rightarrow +\infty} d(f^n(x), f^n(y)) = 0$ (resp. $\lim_{n \rightarrow -\infty} d(f^n(x), f^n(y))$).

If $X$ is locally connected and connected, then every splitting is a Galois covering with a finitely generated group of deck transformations, see Proposition 5.2.

One of the main results of our paper is the following theorem.

**Theorem 1.2.** Let $(X, f)$ be a Smale space such that $X$ is connected and locally connected. Suppose that it has a splitting with a virtually nilpotent group of deck transformations. Then $(X, f)$ is topologically conjugate to a hyperbolic infra-nilmanifold automorphism.

M. Brin in [Bri77, Bri78] gave a “pinching” condition on the Mather spectrum of an Anosov diffeomorphism $(X, f)$ (i.e., spectrum of the operator induced by $f$ on the Banach space of vector fields on $X$) ensuring that $(X, f)$ has a splitting with a virtually nilpotent group of deck transformations. In the case of Anosov diffeomorphisms the splitting map $\pi : M \rightarrow X$ is necessarily the universal covering map, so that the group of deck transformations is the fundamental group of $X$.

M. Brin and A. Manning proved then in [BMS1] that all Anosov diffeomorphisms satisfying the Brin’s pinching condition are hyperbolic automorphisms of infra-nilmanifolds.

We generalize the results of M. Brin and A. Manning. Of course, we can not use the original pinching condition, since we do not have vector fields on Smale spaces. We find, however, a purely topological condition, which follows from Brin’s condition in the case of Anosov diffeomorphism. In fact, we even slightly improve the Brin’s spectral pinching condition for Anosov diffeomorphisms.

Here is an informal description of our condition. Consider a finite covering $R$ of $X$ by small open rectangles. The covering will induce coverings of the stable and unstable leaves by the plaques of the elements of $R$. Define, for a stable leaf $V$ and $x, y \in V$, combinatorial distance $d_R(x, y)$ equal to the smallest length $m$ of a chain $x \in R_0, R_1, \ldots, R_m \ni y$, $R_i \cap R_{i+1} \neq \emptyset$, of plaques of the elements of $R$. Then $d_R(f^n(x), f^n(y))$ grows exponentially for $x \neq y$. We say that $\alpha_0 > 0$ and $\alpha_1 > 0$ are stable lower and upper exponents if there exists $C > 1$ such that

$$C^{-1}e^{\alpha_0 n} \leq d_R(f^n(x), f^n(y)) \leq Ce^{\alpha_1 n}$$

for all stably equivalent $x, y$ such that the distance between $x$ and $y$ inside their stable leaf belongs to some fixed interval $[\epsilon_1, \epsilon_2]$ for $0 < \epsilon_1 < \epsilon_2$. Stable upper and lower critical exponents are the infimum and the supremum of all stable upper and lower exponents, respectively. We prove that stable critical exponents are uniquely determined by the topological conjugacy class of the Smale space and are positive.
and finite. Unstable upper and lower critical exponents are defined in a similar way (they are stable upper and lower critical exponents of \((X, f^{-1})\)). For more details, see Sections 3 and 4.

**Theorem 1.3.** Suppose that \((X, f)\) is a Smale space such that \(X\) is connected and locally connected. Let \(a_0, a_1, b_0, b_1\) be the stable lower and upper, and the unstable lower and upper critical exponents, respectively. If
\[
\frac{a_0}{a_1} + \frac{b_0}{b_1} > 1
\]
then \((X, f)\) is topologically conjugate to a hyperbolic infra-nilmanifold automorphism.

We show that Brin’s pinching condition on the Mather spectrum of an Anosov diffeomorphism implies our condition on the critical exponents.

As an application of Theorem 1.3, we show that the theorem of J. Franks on co-dimension one Anosov diffeomorphisms is true for all locally connected Smale spaces.

**Theorem 1.4.** Let \((X, f)\) be a Smale space such that \(X\) is connected and locally connected, and either stable or unstable equivalence classes of \((X, f)\) are homeomorphic (with respect to their intrinsic topology) to \(\mathbb{R}\). Then \((X, f)\) is topologically conjugate to a hyperbolic linear automorphism of a torus \(\mathbb{R}^n/\mathbb{Z}^n\).

Here intrinsic topology of a leaf is the direct limit topology coming from decomposition of a leaf into the union of plaques of rectangles of \(X\).

**Remark.** A more general notion of an endomorphism of an infra-nilmanifold is discussed in [Dek11b, Dek11a]. It is also noted there that some of the results of [Fra70] and [Shu70] are based on a false result. The proof of Theorem 1.2 shows that it is enough to consider the narrower notion of an automorphism of an infra-nilmanifold in the classification of Smale spaces and Anosov diffeomorphisms up to topological conjugacy. We do not use the results of [Fra70] (except for his proof of Theorem 2.2, which we repeat for our setting). The results of [Shu70] are not used in the proof of Theorem 1.1, where also the narrower notion of an endomorphism of an infra-nilmanifold is used, see [Nek05, Theorem 6.1.6].

**Structure of the paper.** In Section 2 we collect basic facts and definitions related to Smale spaces, and fix the related notations.

We study lower exponents of a Smale space, and a family of metrics associated with lower exponents in Section 3. We also recall there properties of the SRB measures on leaves of Smale spaces.

Locally connected Smale spaces are studied in Section 4. We show that the following conditions for a Smale space \((X, f)\) are equivalent (see Theorem 4.1):

1. The space \(X\) is locally connected.
2. All stable and unstable leaves of \(X\) are locally connected.
3. All stable and unstable leaves of \(X\) are connected.
4. \(X\) has finite stable and unstable upper exponents.

In Section 5 we study splittings of locally connected Smale spaces. We show that for any splitting \(\pi : \mathcal{M} \to X\) of a locally connected Smale space there exists a well defined group of deck transformations \(G\), that \(G\) is finitely generated, and that
there exists a lift $F : \mathcal{M} \to \mathcal{M}$ of $f$ to $\mathcal{M}$, which is unique up to compositions with elements of $G$.

The lift $F$ defines then, for any point $x_0 \in \mathcal{M}$, an automorphism $\phi$ of $G$ by the rule $F(g(x_0)) = \phi(g)(F(x_0))$.

**Question 2.** Does the pair $(G, \phi)$ uniquely determine the topological conjugacy class of $(\mathcal{X}, f)$?

We do not know the answer to this question, but we show that we can reconstruct $(\mathcal{X}, f)$ if we add an extra piece of information to $(G, \phi)$.

**Definition 1.2.** Let $\pi : \mathcal{M} \to \mathcal{X}$ be a splitting of a locally connected and connected Smale space $(\mathcal{X}, f)$. Let $W_+$ and $W_-$ be stable and unstable plaques of a fixed point of a lift of $f$. We say that $\Sigma_+$ and $\Sigma_-$ are coarse stable and unstable plaques if the Hausdorff distances between $\Sigma_+(x_0)$ and $W_+$ and between $\Sigma_-(x_0)$ and $W_-$ are finite.

Here the distance in $\mathcal{M}$ is measured with respect to a $G$-invariant metric.

**Theorem 1.5.** The quadruple $(G, \phi, \Sigma_+, \Sigma_-)$ uniquely determines the topological conjugacy class of $(\mathcal{X}, f)$.

We prove Theorem 1.5 by representing $W_+$ and $W_-$ as boundaries of Gromov hyperbolic graphs constructed using the quadruple. These graphs are quasi-isometric to Cayley graphs of the Ruelle groupoids associated with the Smale space. A general theory of Cayley graphs of hyperbolic groupoids is developed in [Nek11a].

We get the following corollary of Theorem 1.5.

**Theorem 1.6.** Let $(\mathcal{X}_i, f_i)$ for $i = 1, 2$ be connected and locally connected Smale spaces. Let $\pi_i : \mathcal{M}_i \to \mathcal{X}_i$ be lifts of $f_i$. Suppose that $F_i$ have fixed points, and that the groups of deck transformations of $\pi_i$ are both isomorphic to a group $G$. If there exists a continuous map $\Phi : \mathcal{X}_1 \to \mathcal{X}_2$ such that $\Phi(g(x)) = g(\Phi(x))$ and $\Phi(F_1(x)) = F_2(\Phi(x))$ for all $x \in \mathcal{M}_1$ and $g \in G$, then the Smale spaces $(\mathcal{X}_1, f_1)$ and $(\mathcal{X}_2, f_2)$ are topologically conjugate.

Section 6 is devoted to the proof of Theorem 1.2. As the first step we prove the following.

**Proposition 1.7.** Let $\pi : \mathcal{M} \to \mathcal{X}$ be a splitting of a locally connected and connected Smale space $(\mathcal{X}, f)$ such that the group $G$ of deck transformations is torsion free nilpotent. Then $f$ has a fixed point, and the associated automorphism $\phi : G \to G$ is hyperbolic (i.e., its unique extension $\Phi$ to a simply connected nilpotent Lie group containing $G$ as a lattice is hyperbolic).

We prove both statements of Proposition 1.7 by induction on the nilpotency class of $G$.

We show at first that the automorphism $\phi$ induces a hyperbolic automorphism of the center $Z(G) \cong \mathbb{Z}^n$ of $G$. Then we construct an action of $\mathbb{R}^n$ on $\mathcal{M}$ naturally extending the action of $\mathbb{Z}^n$, using the direct product structure on $\mathcal{M}$. The action induces an action of the torus $\mathbb{R}^n/\mathbb{Z}^n$ on $\mathcal{X}$ and agrees with the local product structure, metric on $\mathcal{X}$, and the dynamics, in such a way that the map induced by $f$ on $(\mathbb{R}^n/\mathbb{Z}^n) \setminus \mathcal{X}$ is a Smale space with a splitting with the group of deck transformations isomorphic to $G/Z(G)$. This provides us the necessary inductive steps to prove Proposition 1.7.
Let now \( \pi : M \to X \) be a splitting of a Smale space \((X, f)\) such that its group of deck transformations \(G\) is torsion free nilpotent. The associated automorphism \(\phi : G \to G\) is hyperbolic. Let \(L\) be the unique simply connected nilpotent Lie group such that \(G\) is its lattice (\(L\) is called the Malcev completion of \(G\)). Then \(\phi\) uniquely extends to an automorphism \(\Phi\) of \(L\). Then \(G\) acts on \(L\) by left translations, and we get an Anosov diffeomorphism \(f_L\) of \(G\setminus L\) induced by \(\Phi\).

We use the arguments of [Fra70, Theorem 2.2] to show that there exists a \(G\)-equivariant map \(h : M \to L\). Then it follows from Theorem 1.6 that \((G\setminus L, f_i)\) and \((X, f)\) are topologically conjugate.

Suppose now that the group of deck transformations \(G\) is virtually nilpotent. Then there exists a normal \(\phi\)-invariant torsion free nilpotent subgroup \(G_1\) of \(G\). Let \(L\) be its Malcev completion. We know that there exists a homeomorphism \(h : M \to L\) conjugating the actions of \(G_1\) and the lifts of \(f\) and \(f_L\). Transfer by \(h\) the action of \(G\) on \(M\) to an action of \(G\) on \(L\). We prove in Proposition 6.24 that \(G\) acts then on \(L\) by affine transformations, which finishes the proof of Theorem 1.2.

Theorem 1.3 generalizing the Brin’s pinching condition to Smale spaces is proved in Section 7. We prove at first that every Smale space satisfying conditions of Theorem 1.3 has a splitting (Theorem 7.4). Then we prove that the group of deck transformations of the splitting is virtually nilpotent (Theorem 7.2) using Gromov’s theorem on groups of polynomial growth. Both proofs are similar to the original proofs of M. Brin, except that in the proof of Theorem 7.1 we use results of Section 3 on lower exponents of a Smale space, which allows us to get slightly better pinching condition, and to prove the theorem for all locally connected Smale space, and not only for Anosov diffeomorphisms.

In Section 8 we show how our condition on critical exponents is related to M. Brin’s pinching condition on the Mather spectrum of a diffeomorphism. We show that M. Brin’s condition implies the condition of Theorem 1.3.

Section 9 is devoted to the proof Theorem 7.3 on co-dimension one Smale spaces. We prove it using Theorem 1.3. In fact, a more direct proof can be obtained using the theory of Cayley graphs of hyperbolic groupoids, but at this stage Theorem 1.3 gives us a shorter proof. We show that if stable leaves of a Smale space are homeomorphic to \(\mathbb{R}\), then the stable lower and upper critical exponents coincide (and are equal to the entropy of the Smale space). But this obviously implies that such Smale spaces (if they are locally connected) satisfy the conditions of Theorem 1.3. The fact that co-dimension one hyperbolic automorphisms of an infra-nilmanifold are hyperbolic automorphism of a torus is classical.

Acknowledgments. I started writing this paper during a visit to Institut Mittag-Leffler (Djursholm, Sweden) as a participant of the semester “Geometric and Analytic Aspects of Group Theory”. I am very grateful to the Institute for excellent conditions for work and to the organizers of the semester for inviting me.

This paper is based upon work supported by the National Science Foundation under grant DMS1006280.

2. SMALE SPACES

2.1. Local product structures.

Definition 2.1. A direct product structure on a topological space \(R\) is defined by a continuous map \([\cdot, \cdot] : R \times R \to R\) satisfying
Figure 1. Rectangle

(1) \([x, x] = x\) for all \(x \in R\);
(2) \([x, y, z] = [x, z]\) and \([x, [y, z]] = [x, z]\) for all \(x, y, z \in R\).

We call a space with a direct product structure on it a rectangle.

If \(R = A \times B\) is a decomposition of \(R\) into a direct product of two topological spaces, then the corresponding direct product structure is given by the operation

\[ ((x_1, y_1), (x_2, y_2)) = (x_1, y_2). \]

Let \(R\) be a rectangle. For \(x \in R\) the corresponding plaques are the sets

\( P_1(R, x) = \{ y \in R : [x, y] = x \}, \quad P_2(R, x) = \{ y \in R : [x, y] = y \}. \)

See Figure 1. If \(R = A \times B\) with the corresponding direct product structure, then the plaques are given by

\[ P_1(R, (a, b)) = A \times \{ b \}, \quad P_2(R, (a, b)) = \{ a \} \times B. \]

The map \(P_1(R, x) \times P_2(R, x) \to R\) given by

\[ (y_1, y_2) \mapsto [y_1, y_2] \]

is a homeomorphism.

For any pair \(x, y \in R\) the natural maps \(P_1(R, x) \to P_1(R, y)\) and \(P_2(R, x) \to P_2(R, y)\) given by \(z \mapsto [y, z]\) and \(z \mapsto [z, y]\), respectively, are called holonomy maps inside \(R\), and are homeomorphisms.

These homeomorphism agree with the homeomorphisms \(P_1(R, x) \times P_2(R, x) \to R\), so that we get a canonical decomposition of \(R\) into the direct product of two spaces \(A\) and \(B\), which can be identified with \(P_1(R, x)\) and \(P_2(R, x)\), respectively.

**Definition 2.2.** Let \(X\) be a topological space. A local product structure on \(X\) is given by a covering \(\mathcal{R}\) of \(X\) by open sets \(R\) with a direct product structure \([, [,]_R\) on each of them, such that for any \(R_1, R_2 \in \mathcal{R}\), and for every \(x \in X\) there exists a neighborhood \(U\) of \(x\) such that \([y_1, y_2]_{R_1} = [y_1, y_2]_{R_2}\) for all \(y_1, y_2 \in U \cap R_1 \cap R_2\).

Two coverings of \(X\) by open rectangles define the same local product structures if their union defines a local product structure, i.e., satisfied the above compatibility condition.
If $X$ is a space with a local direct product structure, then an open subset $R \subset X$ with a direct product structure $\cdot \cdot \cdot$ is a (sub-)rectangle of $X$ if the union of $\{ R \}$ with a covering defining the local product structure satisfies the compatibility conditions of Definition 2.2.

We say that a continuous map $f : \mathcal{X}_1 \rightarrow \mathcal{X}_2$ between spaces with local product structures preserves the local product structures if every point of $\mathcal{X}_1$ has a rectangular neighborhood $U$ such that $f(U)$ is a rectangle of $\mathcal{X}_2$, and $f([x, y]_U) = [f(x), f(y)]_{f(U)}$ for all $x, y \in U$.

**Definition 2.3.** Let $X$ be a space with a local product structure. We say that a metric $d$ on $X$ agrees with the local product structure if for every point $x \in X$ there exists an open rectangular neighborhood $R = A \times B$ of $x$ and metrics $d_A$ and $d_B$ on $A$ and $B$, respectively, such that restriction of $d$ onto $R$ is bi-Lipschitz equivalent to the metric $d_R((x_1, y_1), (x_2, y_2)) = d_A(x_1, x_2) + d_B(y_1, y_2)$.

If a metric $d$ agrees with the local product structure, then for every point $x \in X$ there exists a rectangular neighborhood $R$ of $x$ such that all holonomy maps inside $R$ are bi-Lipschitz with respect to the metric $d$ with a fixed Lipschitz constant (depending only on $R$). Conversely, it is easy to see that a metric $d$ agrees with the local product structure if for every $x \in X$ there exists a rectangular neighborhood $R$ of $x$ such that the holonomies inside $R$ are uniformly bi-Lipschitz, and $d(y, z)$ is bi-Lipschitz equivalent to $d([x, y], [x, z])$ + $d([y, x], [z, x])$.

2.2. **Smale spaces.** If $X$ is a compact space with a local product structure on it, then there exists a finite covering of $X$ by rectangles such that the direct product structures on the elements of the covering agree on their intersections. It follows that the local product structure on $X$ can be defined by one map $(x, y) \mapsto [x, y]$ defined on a neighborhood of the diagonal in $X \times X$ and satisfying conditions of Definition 2.1.

**Definition 2.4.** A Smale space is a compact metrizable space $X$ together with a homeomorphism $f : X \rightarrow X$ such that there exists a metric $d$ on $X$, constants $\lambda \in (0, 1)$ and $C > 0$, and a local product structure on $X$ such that $f$ preserves the local product structure and for every $x \in X$ there exists a rectangular neighborhood $R$ of $x$ such that for all $n \geq 0$ and $y, z \in P_1(R, x)$ we have

$$d(f^n(y), f^n(z)) \leq C\lambda^n d(y, z),$$

and for all $n \geq 0$ and $y, z \in P_2(R, x)$ we have

$$d(f^{-n}(y), f^{-n}(z)) \leq C\lambda^n d(y, z).$$

We will denote $P_1(R, x) = P_{+}(R, x)$ and $P_2(R, x) = P_{-}(R, x)$.

**Definition 2.5.** A homeomorphism $f : \mathcal{X} \rightarrow \mathcal{X}$ of a compact space $\mathcal{X}$ is said to be expansive if there exists a neighborhood $U$ of the diagonal in $\mathcal{X} \times \mathcal{X}$ such that $(f^n(x), f^n(y)) \in U$ for all $n \in \mathbb{Z}$ implies $x = y$.

Note that if $U$ satisfies the conditions of the definition, then $\{(x, y) \in \mathcal{X}^2 : (x, y), (y, x) \in U\}$ also satisfies the conditions of the definition. Consequently, we may assume that $U$ is symmetric.

**Proposition 2.1.** Every Smale space is an expansive dynamical system.
Proof. We can find a finite covering $\mathcal{R}$ of $\mathcal{X}$ by rectangles satisfying the conditions of Definition 2.4. Let $\epsilon > 0$ be a Lebesgue's number of the covering. There exists $\delta > 0$ such that for any points $x, y \in \mathcal{X}$ such that $d(x, y) < \delta$ and any rectangle $R \in \mathcal{R}$ such that $x, y \in R$ we have $d(x, [x, y]) < C^{-1}\epsilon$ and $d(y, [x, y]) < C^{-1}\epsilon$.

Let $x, y \in \mathcal{X}$ be such that $d(f^n(x), f^n(y)) < \delta$ for all $n \in \mathbb{Z}$. Then for every $n \in \mathbb{Z}$ there exists a rectangle $R_n \in \mathcal{R}$ such that $f^n(x), f^n(y) \in R_n$. Then $d(f^n(x), [f^n(x), f^n(y)]) < C^{-1}\epsilon$. Note that $f^n(x)$ and $[f^n(x), f^n(y)]$ belong to one plaque $P^-(R_n, f^n(x))$. It follows that $d(f^{n-k}(x), [f^{n-k}(x), f^{n-k}(y)]) \leq CL^k d(f^n(x), [f^n(x), f^n(y)]) < C\lambda^k C^{-1}\epsilon = \lambda^k \epsilon$ for all $k \geq 0$ and all $n \in \mathbb{Z}$. In particular, $d(x, [x, y]) < \lambda^k \epsilon$ for all $k \geq 0$, i.e., $x = [x, y]$. It is shown in the same way that $y = [x, y]$, which implies that $x = y$. Therefore, the set $U \subset \mathcal{X} \times \mathcal{X}$ equal to the set of pairs $(x, y)$ such that $d(x, y) < \delta$ satisfies the conditions of Definition 2.5. □

Definition 2.6. A log-scale on a set $X$ is a function $\ell : \mathcal{X} \times \mathcal{X} \to \mathbb{R} \cup \{\infty\}$ satisfying the following conditions:

1. $\ell(x, y) = \ell(y, x)$ for all $x, y \in X$;
2. $\ell(x, y) = \infty$ if and only if $x = y$;
3. there exists $\Delta > 0$ such that $\ell(x, z) \geq \min\{\ell(x, y), \ell(y, z)\} - \Delta$ for all $x, y, z \in X$.

We say that two log-scales $\ell_1, \ell_2$ are bi-Lipschitz equivalent if the difference $|\ell_1(x, y) - \ell_2(x, y)|$ is uniformly bounded for all $x \neq y$.

Let us describe the natural class of metrics on expansive dynamical systems defined in [Fri83], using log-scales.

Let $(\mathcal{X}, f)$ be an expansive dynamical system. Let $U$ be a symmetric neighborhood of the diagonal, satisfying the conditions of Definition 2.5. Define $\ell(x, y)$ for $x, y \in \mathcal{X}$ to be maximal $n$ such that $(f^n(x), f^n(y)) \in U$ for all $k \in [-n, n]$.

Lemma 2.2. The defined function $\ell$ is a log-scale. It does not depend, up to bi-Lipschitz equivalence, on the choice of $U$.

We call $\ell$ the standard log-scale of the expansive dynamical system.

Proof. We have $\ell(x, y) = \ell(y, x)$, since we assume that $U$ is symmetric. We also have $\ell(x, y) = \infty$ if and only if $x = y$, by Definition 2.5.

It remains to show that there exists $\Delta$ such that $\ell(x, z) \geq \min\{\ell(x, y), \ell(y, z)\} - \Delta$ for all $x, y, z \in \mathcal{X}$.

Since a compact set has a unique uniform structure consisting of all neighborhoods of the diagonal (see [Bou71]), there exists a neighborhood of the diagonal $V \subset \mathcal{X}^2$ such that $(x, y), (y, z) \in V$ implies $(x, z) \in U$.

Note that the sets $U_n = \{(x, y) : \ell(x, y) \geq n\} = \cap_{k=-n}^{n-1} f^k(U)$ are neighborhoods of the diagonal, $U_{n+1} \subseteq U_n$ for all $n$, and $\cap_{n \geq 1} U_n$ is equal to the diagonal. In particular, by compactness of $\mathcal{X}$, there exists $\Delta > 0$ such that $U_\Delta \subseteq V$.

Denote by $V_n = \cap_{k=-n}^{n-1} f^k(V)$ the set of pairs $(x, y)$ such that $(f^n(x), f^n(y)) \in V$ for all $k = -n, \ldots, n$. Then $(x, y), (y, z) \in V_n$ implies $(x, z) \in U_n$.

Then for every $n > \Delta$ we have $U_n \subset V_{n-\Delta}$, since the conditions that $(f^n(x), f^n(y)) \in U$ for all $|k| \leq n$ implies $(f^n(x), f^n(y)) \in U_\Delta \subseteq V$ for all $|k| \leq n - \Delta$.

Let $\min\{\ell(x, y), \ell(y, z)\} = m$. Then $(x, y), (y, z) \in U_m \subset V_{m-\Delta}$, hence $(x, z) \in U_{m-\Delta}$, i.e., $\ell(x, z) \geq m - \Delta$. 

SMAILE SPACES WITH VIRTUALLY NILPOTENT SPLITTING 9
Let us show that \( \ell \) does not depend on the choice of \( U \). Let \( U' \) and \( U'' \) be two neighborhoods of the diagonal, satisfying the conditions of Definition 2.5. Then, as above, there exists \( C > 0 \) such that \( U'_n \subset U'' \) and \( U''_n \subset U' \). By the same arguments as above, we conclude that \( U'_{n+C} \subset U''_n \) and \( U''_{n+C} \subset U'_{n} \) for all \( n \geq 0 \). But this implies that the values of the log-scales defined by \( U' \) and \( U'' \) differ from each other not more than by \( C \).

\[ \Box \]

**Definition 2.7.** Let \((\mathcal{X}, f)\) be an expansive dynamical system, and let \( \ell \) be the standard log-scale. We say that \( x, y \in \mathcal{X} \) are **stable equivalent** (denoted \( x \sim_+ y \)) if \( \ell(f^n(x), f^n(y)) \rightarrow +\infty \) as \( n \rightarrow +\infty \). They are **unstable equivalent** (denoted \( x \sim_- y \)) if \( \ell(f^{-n}(x), f^{-n}(y)) \rightarrow +\infty \) as \( n \rightarrow +\infty \). We call stable and unstable equivalence classes **stable and unstable leaves**.

Note that \( \ell(x_n, y_n) \rightarrow +\infty \) is equivalent to \( d(x_n, y_n) \rightarrow 0 \) for any pair of sequences \( x_n, y_n \in \mathcal{X} \) and for any metric \( d \) on \( \mathcal{X} \).

Two points \( x, y \in \mathcal{X} \) are stably equivalent if and only if \( (f^n(x), f^n(y)) \in U \) for all \( n \) big enough. Denote, for \( x \in \mathcal{X} \) and \( n \in \mathbb{Z} \), by \( W_{n,+}(x) \) the set of points \( y \in \mathcal{X} \) such that \( (f^k(x), f^k(y)) \in U \) for all \( k \geq -n \). Similarly, we denote by \( W_{n,-}(x) \) the set of points \( y \in \mathcal{X} \) such that \( (f^k(x), f^k(y)) \in U \) for all \( k \leq n \).

Then \( W_{n,+}(x) \) and \( W_{n,-}(x) \) are decreasing sequences of sets, and \( W_{+,x} = \bigcup_{n \in \mathbb{N}} W_{+,x}^{n-1} \) and \( W_{-,x} = \bigcup_{n \in \mathbb{N}} W_{-,x}^{n+1} \) are equal to the stable and unstable leaves of \( x \), respectively.

Note that for all \( n \in \mathbb{N} \), \( x \in \mathcal{X} \), \( * \in \{+,-\} \), and \( y_1, y_2 \in W_{n,*}(x) \) we have \( \ell(y_1, y_2) \geq n \).

If \( W \) is a stable leaf, then we denote, for \( y_1, y_2 \in W \), by \( \ell_{\ell}(y_1, y_2) \) and \( \ell_W(y_1, y_2) \) the biggest \( n_0 \) such that \( (f^n(y_1), f^n(y_2)) \in U \) for all \( n \geq -n_0 \).

The following properties of \( \ell_{\ell} \) follow directly from the definitions.

- \( \ell(y_1, y_2) \leq \ell_{\ell}(y_1, y_2) \) for all stably equivalent \( y_1, y_2 \);
- if \( y_1, y_2 \) are stably equivalent and \( \ell_{\ell}(y_1, y_2) > 0 \), then \( \ell(y_1, y_2) = \ell_{\ell}(y_1, y_2) \);
- for all stably equivalent \( y_1, y_2 \) we have

\[
\ell_{\ell}(f(y_1), f(y_2)) = \ell_{\ell}(y_1, y_2) + 1.
\]

Similarly, if \( W \) is an unstable leaf, then \( \ell_{\ell}(y_1, y_2) = \ell_W(y_1, y_2) \), for \( y_1, y_2 \in W \) is the biggest \( n_0 \) such that \( (f^n(y_1), f^n(y_2)) \in U \) for all \( n \leq n_0 \). We also have \( \ell(y_1, y_1) \leq \ell_{\ell}(y_1, y_2), \ell_{\ell}(y_1, y_2) = \ell_{\ell}(y_1, y_2) \) if \( \ell_{\ell}(y_1, y_2) > 0 \), and

\[
\ell_{\ell}(f(y_1), f(y_2)) = \ell_{\ell}(y_1, y_2) - 1
\]

for all pairs \( y_1, y_2 \) of unstably equivalent points.

**Lemma 2.3.** Let \( W \) be a stable or unstable leaf. Then the corresponding function \( \ell_{\ell_{\ell}} \) or \( \ell_{\ell_{W}} \) is a log-scale on \( W \).

**Proof.** If \( \ell_{\ell}(x, y), \ell_{\ell}(y, z), \ell_{\ell}(x, z) \) are all positive, then they are equal to the corresponding values of \( \ell \), hence, by Lemma 2.2, \( \ell_{\ell}(x, z) \geq \min(\ell_{\ell}(x, y), \ell_{\ell}(y, z)) - \Delta \) for \( \Delta \) not depending on \( x, y, z \).

If they are not positive, then we can find \( n \geq 0 \) such that \( \ell_{\ell}(f^n(x), f^n(y)) = \ell_{\ell}(x, y) + n, \ell_{\ell}(f^n(x), f^n(y)) = \ell_{\ell}(x, z) + n \), and \( \ell_{\ell}(f^n(x), f^n(y)) = \ell_{\ell}(y, z) + n \) are positive, and applying the above argument for \( f^n(x), f^n(y), \) and \( f^n(z) \) conclude that \( \ell_{\ell}(x, z) + n \geq \min(\ell_{\ell}(x, y) + n, \ell_{\ell}(y, z) + n) - \Delta \), which is equivalent to \( \ell_{\ell}(x, z) \geq \min(\ell_{\ell}(x, y), \ell_{\ell}(y, z)) - \Delta \). \( \Box \)
We call the log-scales $\ell_+$ and $\ell_-$ the internal log-scales on the respective leaf.

The internal topology on a leaf is the topology defined by the corresponding log-scale $\ell_+$ or $\ell_-$. Here topology defined by a log-scale $\ell$ on a set $X$ is given by the the basis $B(n, x) = \{ y \in X : \ell(x, y) \geq n \}$ of neighborhoods of points $x \in X$. Note that $B(n, x)$ is not necessarily open or closed. Equivalently, the internal topology of a leaf $W$ is equal to the direct limit topology of representation of $W$ as the union of the sequence $W_{n,*}(x)$ for $n \in \mathbb{N}$ and $x \in W$.

Note also that leaves of a Smale space are locally compact, since neighborhoods of points of a leaf are continuous images of neighborhoods of points of $\mathcal{X}$.

3. Lower exponents

3.1. Lower exponents of log-scales. We say that $d$ is a metric associated with a log-scale $\ell$, if there exist constants $\alpha > 0$ and $C > 1$ such that

$$C^{-1}e^{-\alpha \ell(x,y)} \leq d(x,y) \leq Ce^{-\alpha \ell(x,y)}.$$  

The number $\alpha$ is called the exponent of the metric. Topology defined by an associated metric obviously coincides with the topology defined by the log-scale.

Note that if $d$ is a metric associated with $\ell$ of exponent $\alpha$, then for any $0 < r < 1$ the function $(d(x,y))^r$ is a metric associated with $\ell$ of exponent $r\alpha$. It follows that the set of exponents $\alpha$ for which there exists a metric associated with a given log-scale is an interval of the form $(0, \alpha_0)$ or $(0, \alpha_0]$, where $\alpha_0 \in [0, \infty]$. We will see later that $\alpha_0 > 0$ (see also [Nek11a]). The number $\alpha_0$ is the metric critical exponent of the log-scale.

Let $X$ be a set with a log-scale $\ell$. Let $\Gamma_n$, for $n \in \mathbb{R}$, be the graph with the set of vertices $X$ in which two points $x, y$ are connected by an edge if and only if $\ell(x, y) \geq n$. Denote then by $d_n$ the combinatorial distance in $\Gamma_n$ (we assume that $d_n(x, y) = \infty$ if $x$ and $y$ belong to different connected components of $\Gamma_n$).

**Proposition 3.1.** Let $\Delta$ be such as in Definition [27]. There exist $C > 0$ such that

$$d_n(x,y) \geq Ce^{\alpha(n-\ell(x,y))}$$

for all $x, y \in X$ and all $n \in \mathbb{N}$, where $\alpha = \frac{\log 2}{\Delta}$.

**Proof.** If $(x_0, x_1, x_2)$ is a path in $\Gamma_n$, then $\ell(x_0, x_2) \geq n - \Delta$, hence $(x_0, x_2)$ is a path in $\Gamma_{n-\Delta}$. It follows that $d_{n-\Delta}(x,y) \leq \frac{1}{2}(d_n(x,y) + 1)$. In other terms:

$$d_{n+\Delta}(x,y) \geq 2d_n(x,y) - 1.$$

If $\ell(x,y) = m$, then $d_{m+1}(x,y) \geq 2$, and hence

$$d_{m+1+k\Delta}(x,y) \geq 2^{k+1} - 2^{k-1} - 2^{k-2} - \ldots - 1 = 2^k + 1$$

Note that $d_m(x,y) \geq d_n(x,y)$ whenever $m \geq n$. It follows that for $k = \left[ \frac{n-\ell(x,y)-1}{\Delta} \right] \geq \frac{n-\ell(x,y)-1}{\Delta} - 1$ we have

$$d_n(x,y) \geq d_{\ell(x,y)+1+k\Delta}(x,y) > 2^k.$$

Consequently,

$$d_n(x,y) \geq 2^{(n-\ell(x,y)-1-\Delta)/\Delta} = Ce^{\alpha(n-\ell(x,y))}$$

for all $x,y \in X$ and $n \in \mathbb{R}$, where $C = 2^{(-1-\Delta)/\Delta} = \frac{\ln 2}{\Delta}$. \qed
Definition 3.1. We say that $\alpha$ is a lower exponent of a log-scale $\ell$ if there exists $C > 0$ such that
\[
d_n(x, y) \geq Ce^{\alpha(n-\ell(x,y))}
\]
for all $x, y \in X$ and $n \in \mathbb{R}$. Supremum of all lower exponents is called the lower critical exponent.

The proof of the following proposition is straightforward.

Proposition 3.2. Let $\ell_1$ and $\ell_2$ be bi-Lipschitz equivalent log-scales on $X$. A number $\alpha > 0$ is a lower exponent of $\ell_1$ if and only if it is a lower exponent of $\ell_2$.

Theorem 3.3. The metric critical exponent of a log-scale $\ell$ is equal to its lower critical exponent. In particular, the metric critical exponent is positive.

Proof. Let $d$ be a metric on $X$ of exponent $\alpha$ associated with $\ell$, and let $C_1 > 1$ be such that
\[
C_1^{-1}e^{-\alpha\ell(x,y)} \leq d(x,y) \leq C_1e^{-\alpha\ell(x,y)}
\]
for all $x, y \in X$.

Then for every $n$ the inequality $\ell(x,y) \geq n$ implies $d(x,y) \leq C_1e^{-\alpha n}$, hence
\[
d(x,y) \leq C_1d_n(x,y)e^{-\alpha n}
\]
for all $x, y$. It follows that
\[
d_n(x,y) \geq C_1^{-1}d(x,y)e^{\alpha n} \geq C_1^{-2}e^{\alpha n-\alpha\ell(x,y)}.
\]
for all $x, y \in X$ and $n \in \mathbb{N}$, i.e., $\alpha$ is a lower exponent.

Let $\alpha$ be a lower exponent. Let $\beta$ be an arbitrary number such that $\alpha > \beta > 0$.

It is enough to show that there exists a metric on $X$ of exponent $\beta$ associated with $\ell$.

Define, for $x, y \in X$, $d_\beta(x,y)$ as the infimum of $\sum_{i=1}^{m} e^{-\beta \ell(x,x_i)}$ over all sequences $x_0 = x, x_1, x_2, \ldots, x_m = y$. The function $d_\beta(x,y)$ obviously satisfies the triangle inequality, is symmetric, and
\[
d_\beta(x,y) \leq e^{-\beta \ell(x,y)}
\]
for all $x, y \in X$.

It remains to prove that there exists a constant $C_2$ such that for any sequence $x_0 = x, x_1, x_2, \ldots, x_m = y$ we have
\[
\sum_{i=1}^{m} e^{-\beta \ell(x_{i-1},x_i)} \geq C_2e^{-\beta \ell(x,y)}.
\]

Let $C$ be such that $0 < C < 1$ and $d_n(x,y) \geq Ce^{\alpha(n-\ell(x,y))}$ for all $x, y \in X$ and all $n$. Let us prove our statement by induction on $m$ for $C_2 = \exp\left(\frac{\beta(\log C-2\alpha\Delta)}{\alpha-\beta}\right)$.

The statement is true for $m = 1$, since $C_2 < 1$. Suppose that we have proved it for all $k < m$, let us prove it for $m$.

Lemma 3.4. Let $x_0, x_1, \ldots, x_m$ be a sequence such that $\ell(x_i, x_{i+1}) \geq n$ for all $i = 0, 1, \ldots, m-1$. Let $n_0 \leq n$. Then there exists a sub-sequence $y_0 = x_0, y_1, \ldots, y_{t-1}, y_t = x_m$ of the sequence $x_i$ such that
\[
n_0 - 2\Delta \leq \ell(y_i, y_{i+1}) < n_0
\]
for all $i = 0, 1, \ldots, t - 1$. 

Proof. Let us construct the subsequence \( y_i \) by the following algorithm. Define \( y_0 = x_0 \). Suppose we have defined \( y_i = x_r \) for \( r < m \). Let \( \ell \) be the largest index such that \( \ell > r \) and \( \ell(x_r, x_s) \geq n_0 \). Note that since \( \ell(x_r, x_{r+1}) \geq n \geq n_0 \), such \( \ell \) exists.

If \( s < m \), then \( \ell(x_r, x_{s+1}) < n_0 \), and

\[
\ell(x_r, x_{s+1}) \geq \min\{\ell(x_r, x_s), \ell(x_s, x_{s+1})\} - \Delta \geq \min\{n_0, \ell(x_s, x_{s+1})\} = \Delta = n_0 - \Delta.
\]

Define then \( y_i = x_{s+1} \). We have

\[
n_0 - \Delta \leq \ell(y_i, y_{i+1}) < n_0.
\]

If \( s + 1 = m \), we stop and get our sequence \( y_0, \ldots, y_t \), for \( t = i + 1 \).

If \( s = m \), then \( \ell(x_r, x_m) = \ell(y_i, x_m) \geq n_0 \), and

\[
\ell(y_{i-1}, x_m) = \min\{\ell(y_{i-1}, y_i), \ell(y_i, x_m)\} - \Delta \geq \min\{n_0 - \Delta, n_0\} = n_0 - 2\Delta
\]

and

\[
\ell(y_{i-1}, x_m) < n_0,
\]

since \( y_i \) was defined and was not equal to \( x_m \). Then we redefine \( y_i = x_m \) and stop the algorithm.

In all the other cases we repeat the procedure. It is easy to see that at the end we get a sequence \( y_i \) satisfying the conditions of the lemma. \( \square \)

Let \( x_0 = x, x_1, \ldots, x_m = y \) be an arbitrary sequence of points of \( X \). Let \( n_0 \) be the minimal value of \( \ell(x_i, x_{i+1}) \). Let \( y_0 = x, y_1, \ldots, y_t = y \) be a sub-sequence of the sequence \( x_i \) satisfying conditions of Lemma 5.4.

Suppose at first that

\[
n_0 < \ell(x, y) + \frac{2\alpha \Delta - \log C}{\alpha - \beta}.
\]

Remember that \( n_0 = \ell(x_i, x_{i+1}) \) for some \( i \), hence

\[
\sum_{i=1}^{m} e^{-\beta \ell(x_{i-1}, x_i)} \geq e^{-\beta n_0} \geq \exp\left(-\beta \ell(x, y) - \frac{\beta(2\alpha \Delta - \log C)}{\alpha - \beta}\right) = C_2 e^{-\beta \ell(x, y)},
\]

and the statement is proved.

Suppose now that \( n_0 \geq \ell(x, y) + \frac{2\alpha \Delta - \log C}{\alpha - \beta} \), which is equivalent to

\[
\alpha - \beta \geq \ell(x, y) + \frac{2\alpha \Delta - \log C}{\alpha - \beta} - \frac{2\alpha \Delta - \log C}{\alpha - \beta} = \ell(x, y) - 2\alpha \Delta + \log C \geq 0.
\]

If \( t = 1 \), then \( n_0 - 2\Delta \leq \ell(x, y) < n_0 \), hence

\[
n_0 \leq \ell(x, y) + 2\Delta = \ell(x, y) + \frac{2\alpha \Delta - 2\beta \Delta}{\alpha - \beta} < \ell(x, y) + \frac{2\alpha \Delta - \log C}{\alpha - \beta},
\]

since \( \log C < 0 < 2\beta \Delta \). But this contradicts our assumption.

Therefore \( t > 1 \), and the inductive assumption implies

\[
\sum_{i=1}^{m} e^{-\beta \ell(x_{i-1}, x_i)} \geq \sum_{i=0}^{t-1} C_2 e^{-\beta \ell(x_{i+1}, y_{i+1})} > tC_2 e^{-\beta n_0}.
\]
We have \( t \geq d_{n_0-2\Delta}(x,y) \geq C e^{\alpha(n_0-2\Delta-\ell_W(x,y))} \), hence
\[
\sum_{i=1}^{m} e^{-\beta \ell(x_{i-1},x_i)} \geq CC_2 e^{-\beta n_0+\alpha n_0-2\alpha \Delta-\alpha \ell(x,y)} = C_2 \exp \left( \log C - \beta n_0 + \alpha n_0 - 2\alpha \Delta - \alpha \ell(x,y) \right) =
C_2 \exp \left( -\beta \ell(x,y) + (\alpha - \beta)n_0 - (\alpha - \beta)\ell(x,y) - 2\alpha \Delta + \log C \right) \geq C_2 e^{-\beta \ell(x,y)}, \]
by (5).

3.2. Lower exponents of Smale spaces.

**Definition 3.2.** Let \((X,f)\) be a Smale space. A number \(\alpha > 0\) is a **stable** (resp. **unstable**) lower exponent of the Smale space if there exists a constant \(C > 0\) such that for any stable (resp. unstable) leaf \(W\) and any \(x, y \in W\) we have
\[
d_n(x,y) \geq C e^{\alpha(n-\ell_W(x,y))}
\]
for the internal log-scale on \(W\). The supremum of the stable (resp. unstable) lower exponents is called the **stable** (resp. **unstable**) lower critical exponent.

Note that by Proposition 2.4 lower stable and unstable exponents exist and are positive for any Smale space. Proposition 3.2 implies that the lower critical exponents of a Smale space depend only on the topological conjugacy class of the Smale space.

**Proposition 3.5.** Let \(l \in \mathbb{R}\). A number \(\alpha > 0\) is a lower stable (resp. unstable) exponent of \((X,f)\) if and only if there exists \(C_l > 0\) such that for every stable (resp. unstable) leaf \(W\) and for every two points \(x, y \in W\) such that \(\ell_W(x,y) \leq l\) we have
\[
d_n(x,y) \geq C_l e^{\alpha n}
\]
for all \(n\).

**Proof.** Let us assume that \(W\) is a stable leaf (the proof for an unstable leaf is the same). If \(\alpha\) is a lower exponent and \(C\) is as in Definition 3.2 then for any \(x, y \in W\) such that \(\ell_W(x,y) \leq l\) we have
\[
d_n(x,y) \geq C e^{\alpha(n-\ell_W(x,y))} \geq C e^{-\alpha l} \cdot e^{\alpha n},
\]
and we can take \(C_l = C e^{-\alpha l}\).

Suppose now that \(C_l > 0\) is such that \(d_n(x,y) \geq C_l e^{\alpha n}\) for all \(x, y\) belonging to one stable leaf \(W\) and such that \(\ell_W(x,y) \geq l\).

Let \(x\) and \(y\) be arbitrary stably equivalent points of \(X\). Let \(W_0\) be their stable leaf. Denote \(n_0 = \ell_W(x,y)\). Then \(\ell_W(f^{l-n_0}(x), f^{l-n_0}(y)) = l\), where \(W\) is the stable leaf of \(f^{l-n_0}(x) \sim_+ f^{l-n_0}(y)\). Consequently,
\[
d_n(f^{l-n_0}(x), f^{l-n_0}(y)) \geq C_l e^{\alpha n}
\]
for all \(n\).

The map \(z \mapsto f^{l-n_0}(z)\) transforms every path in \(\Gamma_n(W_1)\) to a path in \(\Gamma_{n+l-n_0}(W_2)\), where \(W_1\) and \(W_2\) are the stable leaves of \(z\) and \(f^{l-n_0}(z)\), see (3).

It follows that
\[
d_n(x,y) \geq d_{n+l-n_0}(f^{l-n_0}(x), f^{l-n_0}(y)) \geq C_l e^{\alpha(n+l-n_0)} = C_l e^{\cdot} e^{\alpha(n-\ell_W(x,y))},
\]
which shows that \(\alpha\) is a lower exponent.
3.3. **Metric properties of leaves.** Let \((\mathcal{X}, f)\) be a Smale space, and let \(\ell, \ell_+\), and \(\ell_-\) be the standard log-scale on \(\mathcal{X}\), and the internal log-scales on the stable and unstable leaves of \(\mathcal{X}\). Let \(U\) be a neighborhood of the diagonal satisfying the conditions of Definition 2.5.

The following theorem describes the classical theory of Sinai-Ruelle-Bowen measure on Smale spaces, see [Bow71]. See its exposition in [Nek11b], which is notationally close to our paper.

Denote by \(d, d_+, \) and \(d_-\) metrics associated with the log-scales \(\ell, \ell_+, \) and \(\ell_-\), respectively. Denote by \(B^* (r, x)\) the ball of radius \(r\), with respect to the metric \(d^*\), with center in \(x\), where \(* \in \{+,-\}\).

**Theorem 3.6.** There exists a number \(\eta > 0\) (called the entropy of \((\mathcal{X}, f)\)), and a family of Radon measures \(\mu_+\) and \(\mu_-\) on the stable and unstable leaves of \(\mathcal{X}\) satisfying the following properties.

1. There exists a number \(C > 1\) such that
   \[
   C^{-1} r^{\eta/\alpha*} \leq \mu_* (B_* (r, x)) \leq C r^{\eta/\alpha*}
   \]
   for all \(r \geq 0, x \in \mathcal{X}\), and \(* \in \{+,-\}\).
2. The measures are preserved under holonomies.
3. The measures are quasi-invariant with respect to \(f\), and \(
   \frac{d f_* (\mu_*)}{d \mu_*} = e^{\eta*},
   \)

It follows from condition (1) of the theorem, that \(\mu_+\) and \(\mu_-\) are equivalent to the Hausdorff measures of the metrics \(d_+\) and \(d_-\) of dimension \(\frac{\eta}{\alpha_+}\) and \(\frac{\eta}{\alpha_-}\), respectively.

4. **Locally connected Smale spaces and upper exponents**

4.1. **Connectivity.** The aim of this section is to prove the following description of locally connected Smale spaces.

**Theorem 4.1.** Let \((\mathcal{X}, f)\) be a Smale space. The following conditions are equivalent.

1. The space \(\mathcal{X}\) is locally connected.
2. All stable and unstable leaves are locally connected.
3. All stable and unstable leaves are connected.
4. The graphs \(\Gamma_0 (W)\) are connected for every (stable or unstable) leaf \(W\).
5. The graphs \(\Gamma_n (W)\) are connected for every leaf \(W\) and every \(n\).
6. There exist \(\alpha > 0\) and \(C > 0\) such that for every leaf \(W\) we have
   \[
   d_n (x, y) \leq C e^{\alpha (n - \ell_W (x, y))}
   \]
   for all \(x, y \in W\) and all \(n \geq \ell_W (x, y)\).

Recall that for a stable or unstable leaf \(W\), we denote by \(\Gamma_n (W)\) the graph with the set of vertices \(W\) in which two vertices \(x, y\) are connected by an edge if and only if \(\ell_W (x, y) \geq n\), where \(\ell_W\) is the corresponding \((\ell_+\) or \(\ell_-)\) internal log-scale on \(W\).

Let us start by proving equivalence of conditions (1) and (2).

**Proposition 4.2.** Let \((\mathcal{X}, f)\) be a Smale space. The space \(\mathcal{X}\) is locally connected if and only if each leaf is locally connected.
Proposition 4.5. The following conditions are equivalent.

\[ \text{Γ} \text{ } x, y \text{ diagonal defining} \]

Proof. Each point \( x \in \mathcal{X} \) has a neighborhood homeomorphic to the direct product of the neighborhoods of \( x \) in the corresponding stable and unstable leaves. It follows that if \( x \) has bases of connected neighborhoods in the leaves, then \( x \) has a basis of connected neighborhoods in \( \mathcal{X} \).

In the other direction, if \( x \) has a basis of connected neighborhoods in \( \mathcal{X} \), then for any rectangular neighborhood \( R \) of \( x \) there exists a connected neighborhood \( U \subset R \) of \( x \). Its projection onto the direct factors of \( R \) will be connected, hence the point \( x \) has bases of connected neighborhoods in its leaves. \( \square \)

**Proposition 4.3.** If every stable leaf of \((\mathcal{X}, f)\) is locally connected, then every stable leaf of \((\mathcal{X}, f)\) is connected.

Proof. For every point \( x \in \mathcal{X} \) there exists a connected neighborhood \( U \) of \( x \) in its stable leaf and a rectangular neighborhood \( R \) of \( x \) in \( \mathcal{X} \) such that \( P_+(R, x) = U \). Then each plaque of \( R \) will be homeomorphic to \( U \), hence will be connected. It follows that every point of \( \mathcal{X} \) has a rectangular neighborhood \( R \) such that all its stable plaques are connected. Since \( \mathcal{X} \) is compact, there exists a finite covering \( \mathcal{R} = \{R_i\} \) of \( \mathcal{X} \) by open rectangles with connected stable plaques.

Let \( W \) be a stable leaf, and let \( x, y \in W \). By Lebesgue’s covering lemma, there exists \( n \) such that \( f^n(x) \) and \( f^n(y) \) belong to one plaque \( V \) of a rectangle \( R_i \in \mathcal{R} \). Then \( f^{-n}(V) \) is a connected subset of \( W \) containing \( x \) and \( y \). We have shown that any two points of \( W \) belong to one connected component of \( W \), i.e., that \( W \) is connected. \( \square \)

Let \( \mathcal{R} = \{R_i\}_{i \in I} \) be a finite covering of \( \mathcal{X} \) by open rectangles. Let \( \mathcal{R}_+ \) be the set of all stable plaques of elements of \( \mathcal{R} \).

Every stable leaf \( W \) is a union \( \bigcup_{T \in \mathcal{R}_+, T \subset W} T \) of stable plaques contained in \( W \). Each plaque is an open subset of \( W \) and the internal topology on \( W \) coincides with the direct limit topology of the union of the plaques.

Denote by \( \Gamma_n(W) \) the graph with the set of vertices \( W \) in which two vertices are connected by an edge if they belong to one set of the form \( f^n(T), T \in \mathcal{R}_+ \).

The map \( f : W \rightarrow f(W) \) induces isomorphisms \( \Gamma_n(W) \rightarrow \Gamma_{n+1}(W) \) and \( \Gamma_n(W) \rightarrow \Gamma_{n+1}(W) \), see \( \square \) and \( \square \) for the first isomorphism.

**Lemma 4.4.** There exists a number \( k_0 \) such that if \( x, y \in W \) are adjacent in \( \Gamma_n(W) \), then they are adjacent in \( \Gamma_{n-k_0}(W) \), and if \( x, y \in W \) are adjacent in \( \Gamma_n(W) \), then they are adjacent in \( \Gamma_{n-k_0}(W) \).

Proof. There exists \( k_1 \) such that for every plaque \( V \in \mathcal{R}_+ \) and every pair \( x, y \in V \) we have \((f^k(x), f^k(y)) \in U \) for all \( k \geq k_1 \) (where \( U \) is a neighborhood of the diagonal defining \( \ell, \ell_+ \), and \( \ell_- \)). If \( x, y \in W \) are connected by an edge in \( \Gamma_n(W) \), then \( x, y \in f^n(T) \) for \( T \in \mathcal{R}_+ \), hence \((f^{k-n}(x), f^{k-n}(y)) \in U \) for all \( k \geq k_1 \), hence \( \ell(x, y) \geq n - k_1 \), i.e., \( x \) and \( y \) are connected by an edge in \( \Gamma_{n-k_1}(W) \).

By Lebesgue’s covering lemma, there exists \( k_2 \) such that if \( x, y \in W \) are such that \( \ell_W(x, y) \geq k_2 \), then \( x \) and \( y \) belong to one plaque \( V \in \mathcal{R}_+ \). Then every edge of \( \Gamma_{k_2}(W) \) is an edge in \( \Gamma_k(W) \). Consequently, every edge of \( \Gamma_n(W) \) is an edge in \( \Gamma_{n-k_2}(W) \). \( \square \)

**Proposition 4.5.** The following conditions are equivalent.

1. The graph \( \Gamma_0(W) \) is connected for every stable leaf \( W \).
2. The graph \( \Gamma_n(W) \) is connected for every stable leaf \( W \) and for every \( n \in \mathbb{Z} \).
(3) The graph $\Gamma'_0(W)$ is connected for every stable leaf $W$.
(4) The graph $\Gamma'_n(W)$ is connected for every stable leaf $W$ and for every $n \in \mathbb{Z}$.

Proof. Since the map $f^n : W \rightarrow f^n(W)$ induces isomorphisms $\Gamma_n(W) \rightarrow \Gamma_{n+k}(W)$ and $\Gamma'_n(W) \rightarrow \Gamma'_{n+k}(W)$, (1) is equivalent to (2), and (3) is equivalent to (4).

Let $k_0$ be as in Lemma 4.4. If all graphs $\Gamma_n(W)$ are connected, then all graphs $\Gamma'_n(W)$ are connected. If all graphs $\Gamma'_n(W)$ are connected, then all graphs $\Gamma_{n-k_0}(W) \supset \Gamma'_n(W)$ are connected. This shows that all conditions (1)–(4) are equivalent to each other.

Proposition 4.6. If a stable leaf $W$ is connected, then the graph $\Gamma'_n(W)$ is connected for every $n$.

Proof. Suppose that $W$ is a connected stable leaf. Let $A$ be a connected component of $\Gamma'_0(W)$. Let $W_A$ be the union of the plaques $V \in R_+$ containing vertices of $A$. It follows from the definition of the graph $\Gamma'_0(W)$ that every plaque $V \in R_+$ is either contained in $W_A$, or is disjoint with it. Consequently, $W_A$ is clopen, which implies that $W = W_A$, hence $A = W$, and $\Gamma'_0(W)$ is connected.

Proposition 4.7. Suppose that the graphs $\Gamma'_n(W)$ are connected for all stable leaves $W$ and all $n$. Then there exists $A \geq 1$ such that any two adjacent vertices in $\Gamma'_0(W)$ are on distance at most $A$ in $\Gamma'_1(W)$.

Proof. Let $E$ be the closure in $\mathcal{A} \times \mathcal{A}$ of the set pairs of points $(x, y)$ such that there exists a plaque $V \in R_+$ such that $x, y \in V$. It is easy to see that $E$ is compact. It contains the set of edges of every graph $\Gamma'_0(W)$, and is contained in the stable equivalence relation.

Any pair of points $x, y$ such that $(x, y) \in E$ is connected by a path in $\Gamma'_1(W)$, as all graphs $\Gamma'_n(W)$ are connected. It means that there exists a sequence of rectangles $R_1, \ldots, R_n \in R$, and a sequence of points $x_i \in R_i$ such that $x$ and $x_1$ belong to the same stable plaque of $R_1$, $y$ and $x_n$ belong to the same stable plaque of $R_n$, and the stable plaque of $x_i$ in $R_i$ intersects with the stable plaque of $x_{i+1}$ in $R_{i+1}$. This sequence $R_1, \ldots, R_n$ will define a path in $\Gamma'_1(W)$ connecting any two points $(x', y')$ belonging to a neighborhood of $(x, y)$ in $E$. It follows then from compactness of $E$ that we can find a finite upper bound on the length of a path connecting any two points of $E$, which finishes the proof.

Recall that $d_n(x, y)$ is the distance in the graph $\Gamma_n(W)$.

Proposition 4.8. Suppose that all graphs $\Gamma'_n(W)$ are connected. Then there exist positive constants $\alpha$ and $C$ such that for any two points $x, y \in W$ we have

$$d_n(x, y) \leq C e^{\alpha (n - \ell_W(x, y))}$$

for all $n \geq \ell_W(x, y)$.

Proof. Let $A$ and $k_0$ be as in Propositions 4.4 and 4.3 and let $x, y \in W$ be arbitrary. Denote $n_0 = \ell_W(x, Y)$. The points $x$ and $y$ are connected by an edge in $\Gamma_{n_0}(W)$, hence they are connected by an edge in $\Gamma'_{n_0-k_0}(W)$. It follows from Proposition 4.4 that for every $k \geq 0$, distance between $x$ and $y$ in $\Gamma'_{n_0-k_0+k}(W)$ is not greater than $A^k$. As the set of edges of $\Gamma'_{n_0-k_0+k}(W)$ is contained in the set of edges of $\Gamma_{n_0-2k_0+k}(W)$, we have

$$d_{n_0-2k_0+k}(x, y) \leq A^k.$$
for all $k \geq 0$. Consequently,
\[ d_n(x, y) \leq A^{n-n_0+2k_0} = A^{2k_0} \cdot A^n - \ell_W(x, y) \]
for all $n \geq \ell_W(x, y) - 2k_0$. \qed

**Proposition 4.9.** Suppose that all graphs $\Gamma'_n(W)$ are connected. Let $d$ be a metric on $W$ associated with $\ell_W$. There exists a constant $C$ such that for any two points $x, y \in W$ there exists a curve $\gamma : [0, 1] \to W$ connecting $x$ to $y$ and such that the diameter the range of $\gamma$ is not larger than $Cd(x, y)$.

**Proof.** Let $A$ and $k_0$ be as in Propositions 4.7 and 4.8. Let $C_1 > 1$ and $\alpha > 0$ be such that $C_1^{-1}e^{-\alpha W(x, y)} \leq d(x, y) \leq C_1e^{-\alpha W(x, y)}$ for all $x, y \in W$.

Take arbitrary $x, y \in W$. Let $n_0 = \ell_W(x, y)$. Then $x$ and $y$ are adjacent in $\Gamma''_{n_0-k_0}(W)$, hence they are connected by a path $\gamma_1 : \{x = x_{1,1}, x_{1,2}, \ldots, x_{1,m_1} = y\}$ of length at most $A$ in $\Gamma''_{n_0-k_0+1}(W)$. Each pair of points $x_{1,i}, x_{1,i+1}$ is connected by a path of length at most $A$ in $\Gamma''_{n_0-k_0+2}(W)$. We get then a path $\gamma_2 = \{x = x_{2,1}, x_{2,2}, \ldots, x_{2,m_2} = y\}$ of length at most $A^2$ in $\Gamma''_{n_0-k_0+2}(W)$, containing $\gamma_1$. We get then inductively defined sequence of paths $\gamma_n = \{x = x_{n,1}, x_{n,2}, \ldots, x_{n,m_n} = y\}$ in $\Gamma''_{n_0-k_0+n}(W)$ such that each next path $\gamma_n$ is obtained from $\gamma_{n-1}$ by inserting at most $A - 1$ points between each pair of neighbors of $\gamma_n$.

Every pair of points $x_{n,j}, x_{n,j+1}$ is adjacent in $\Gamma''_{n_0-k_0+n}(W)$, hence $\ell_W(x_{n,j}, x_{n,j+1}) \geq n_0 - 2k_0 + n$, hence $d(x_{i,j}, x_{i,j+1}) \leq C_1e^{-\alpha(n+n_0-2k_0)}$. In particular, for every point of $\gamma_{n+1}$ there exists a point of $\gamma_n$ on distance less than $AC_1e^{-\alpha(n+1+n_0-2k_0)}$.

It follows that diameter of the set $\gamma_n$ is not greater than
\[
C_1e^{-\alpha(n_0-2k_0)} + 2 \sum_{i=1}^{n} AC_1e^{-\alpha(i+n_0-2k_0)} <
2C_1Ae^{-\alpha(n_0-2k_0)} \cdot \frac{1}{1 - e^{-\alpha}}.
\]

Since $d(x_{n,j}, x_{n,j+1}) \leq C_1e^{-\alpha(n_0-2k_0+n)}$, the closure of $\bigcup_{n=1}^{\infty} \gamma_n$ is the image of a continuous curve connecting $x$ to $y$. Diameter of the image of the curve is not greater than $2C_1^2A^{2k_0}e^{-\alpha(n_0-2k_0+n)}$. \qed

Let us summarize now the proof of Theorem 4.1. Equivalence of (1) and (2) is shown in Proposition 4.2. Implication (2)$\Rightarrow$(3) is given in Proposition 4.3. Equivalence of (4) and (5) is contained in Proposition 4.4. Proposition 4.5 shows that (3) implies (4). Proposition 4.6 proves that (5) implies (6). Condition (6) obviously implies (5). Proposition 4.7 shows that (5) implies connectivity and local connectivity of the leaves, i.e., that (5) implies (2) and (3).

This finishes the proof of Theorem 4.1.

**4.2. Local product structure on locally connected Smale spaces.**

**Proposition 4.10.** Let $R$ be a sub-rectangle of a Smale space $(X, f)$. If $R$ is connected and locally connected, then the direct product structure on $R$ compatible with the local product structure on $X$ is unique.
Proof. Suppose that, on the contrary, there exist two different direct product structures $[\cdot, \cdot]_1$ and $[\cdot, \cdot]_2$, both compatible with the local product structure on $X$.

By Definition 2.2 there exists a covering $R$ of $X$ by open rectangles such that for any $U \in R$ and $x, y \in R \cap U$ we have $[x, y]_U = [x, y]_1 = [x, y]_2$. Then for every $U \in R$ the intersection $U \cap R$ is a (possibly empty) sub-rectangle of $R$ with respect to both direct product structures; and restrictions of the direct products structures $[\cdot, \cdot]_i$, $i = 1, 2$, onto $U \cap R$ coincide.

Since $R$ is connected, all plaques of $R$ (with respect to both direct products structures) are connected. Let $P_+$ be a stable plaque of $(R, [\cdot, \cdot]_1)$. Let $x, y \in P_+$. Since $P_+$ is connected, there exists a sequence of points $x_0 = x, x_1, \ldots, x_n = y$ and a sequence of rectangles $U_0, U_1, \ldots, U_n \in R$ such that $x_i \in U_i$, and $U_i \cap U_{i+1} \cap P_+ \neq \emptyset$. The set $U_i \cap P_+$ is a plaque of the rectangle $U_i \cap R$, hence it is a subset of the stable plaque of $(R, [\cdot, \cdot]_2)$. We get a sequence $U_i \cap P_+$ of subsets of plaques of $(R, [\cdot, \cdot]_2)$ such that $(U_i \cap P_+) \cap (U_{i+1} \cap P_+) \neq \emptyset$. But it means that $U_i \cap P_+$ are subsets of one plaque of $(R, [\cdot, \cdot]_2)$. We have shown that if two points belong to one stable plaque of $(R, [\cdot, \cdot]_1)$, then they belong to one stable plaque of $(R, [\cdot, \cdot]_2)$. The converse is proved in the same way. Consequently, the stable plaques of $R$ with respect to $[\cdot, \cdot]_1$ are the same as the stable plaques of $R$ with respect to $[\cdot, \cdot]_2$. The same statement is obviously true for the unstable plaques, which implies that the direct product structures $[\cdot, \cdot]_1$ and $[\cdot, \cdot]_2$ on $R$ coincide. □

4.3. Upper exponents.

**Definition 4.1.** A positive number $\alpha > 0$ is a stable (resp. unstable) upper exponent of the Smale space if there exists $C > 0$ such that for any stable (resp. unstable) leaf $W$ and every pair of points $x, y \in W$ we have

$$d_n(x, y) \leq C e^{\alpha(n - \ell_W(x, y))}$$

for all $n \geq \ell_W(x, y)$.

Note that changing $\ell_W$ to a bi-Lipschitz equivalent log-scale, one does not change the set of upper exponents, i.e., this notion is well defined and depends only on the topological conjugacy class of the Smale space (see Lemma 2.2).

By Theorem 4.1 a finite upper exponent exists if $X$ is locally connected.

The proof of the next proposition is analogous to the proof of Proposition 3.5.

**Proposition 4.11.** Fix $l \in \mathbb{R}$. A number $\alpha > 0$ is a stable (resp. unstable) upper exponent if and only if there exists a constant $C_l > 0$ such that for any stable (resp. unstable) leaf $W$ and any $x, y \in W$ such that $\ell_W(x, y) \geq l$ we have

$$d_n(x, y) \leq C_l e^{\alpha n}$$

for all $n \geq 0$.

5. Splittings of Smale spaces

5.1. Groups of deck transformations.

**Definition 5.1.** Let $(\mathcal{X}, f)$ be a Smale space. A splitting of $(\mathcal{X}, f)$ is a covering map $\pi : \mathcal{M} \to \mathcal{X}$, where $\mathcal{M}$ is a space with a (global) direct product structure, such that

1. $\pi$ agrees with the local product structures on $\mathcal{M}$ and $\mathcal{X}$;
(2) restriction of $\pi$ onto every plaque $P_1(\mathcal{M}, x)$ of $\mathcal{M}$ is a homeomorphism with the stable leaf $W_+(\pi(x))$, and restriction of $\pi$ onto every plaque $P_2(\mathcal{M}, x)$ of $\mathcal{M}$ is a homeomorphism with the unstable leaf $W_-(\pi(x))$, with respect to their intrinsic topology.

**Proposition 5.1.** Suppose that $\mathcal{X}$ is connected and locally connected. Let $\pi_1 : \mathcal{M}_1 \rightarrow \mathcal{X}$ and $\pi_2 : \mathcal{M}_2 \rightarrow \mathcal{X}$ be splittings of $(\mathcal{X}, f)$. If $x_1 \in \mathcal{M}_1$ and $x_2 \in \mathcal{M}_2$ are such that $\pi_1(x_1) = \pi_2(x_2)$, then there exists a unique homeomorphism $F : \mathcal{M}_1 \rightarrow \mathcal{M}_2$ preserving the local product structures and such that $\pi_1 = \pi_2 \circ F$ and $F(x_1) = x_2$.

**Proof.** Since the leaves of locally connected Smale spaces are connected and locally connected, the spaces $\mathcal{M}_i$ are connected and locally connected.

Denote $x = \pi_1(x_1) = \pi_2(x_2)$. Restriction of $\pi_i$ onto the plaques $P_i(\mathcal{M}_i, x_i)$ and $P_2(\mathcal{M}_i, x_i)$ are homeomorphisms with the leaves $W_+(x)$ and $W_-(x)$, respectively. Therefore, the only possible way to define $F$ is by the equality

$$F([y_1, y_2]_{\mathcal{M}_1}) = [z_1, z_2]_{\mathcal{M}_2},$$

where $y_1 \in P_1(\mathcal{M}_1, x_1)$, $y_2 \in P_2(\mathcal{M}_1, x_1)$ are arbitrary, while $z_1 \in P_1(\mathcal{M}_2, x_2)$, $z_2 \in P_2(\mathcal{M}_2, x_2)$ are uniquely determined by the condition $\pi_1(y_1) = \pi_2(z_1)$ and $\pi_1(y_2) = \pi_2(z_2)$.

The defined map $F$ is a homeomorphism, since it is a direct product of two homeomorphisms. Consequently, $\pi_2 \circ F : \mathcal{M}_1 \rightarrow \mathcal{X}$ is a covering map. Since $F$ and $\pi_2$ agree with the local product structures of $\mathcal{M}_1$ and $\mathcal{X}$, their composition $\pi_2 \circ F$ agrees with the local product structures, i.e., the image of the direct product structure on $\mathcal{M}_1$ by $F$ defines the same local product structure on $\mathcal{M}_2$ as the direct product structure $[\cdot, \cdot]_{\mathcal{M}_2}$. By the same arguments as in the proof of Proposition 4.10, the direct product structure on $\mathcal{M}_2$ is uniquely determined by the corresponding local product structure. Consequently, $F$ preserves the direct product structures, i.e., $F([y_1, y_2]_{\mathcal{M}_1}) = [F(y_1), F(y_2)]_{\mathcal{M}_2}$ for all $y_1, y_2 \in \mathcal{M}_1$. It follows that if $\pi_1(y) = \pi_2(F(y))$ for $y \in \mathcal{M}_1$, then $\pi_1 = \pi_2 \circ F$ on a rectangular neighborhood of $y$. Consequently, the set of points $y \in \mathcal{M}_1$ such that $\pi_1(y) = \pi_2(F(y))$ is open and closed, it contains $x$, hence it is equal to $\mathcal{M}_1$.

We assume now that $(\mathcal{X}, f)$ is a locally connected and connected Smale space.

Let $\pi : \mathcal{M} \rightarrow \mathcal{X}$ be a splitting. Let $G$ be the set of all homeomorphisms $g : \mathcal{M} \rightarrow \mathcal{M}$ preserving the direct product structure on $\mathcal{M}$ and such that $\pi = \pi_0 \circ F$. Then $G$ is obviously a group. By Proposition 5.1 (for the case $\pi_1 = \pi_2$), the action of the group on $\mathcal{M}$ is free and transitive on $\pi^{-1}(x)$ for every $x \in \mathcal{X}$. We call $G$ the group of deck transformations of the splitting. It acts properly on $\mathcal{M}$, since every point of $\mathcal{M}$ has a neighborhood $U$ such that $\pi(U)$ is evenly covered, i.e., such that $g(U) \cap U = \emptyset$ for all not-trivial $g \in G$.

Note that if $\pi : \mathcal{M} \rightarrow \mathcal{X}$ is a splitting, then $\pi \circ f$ is also a splitting. Choose $x_1, x_2 \in \mathcal{M}$ such that $f \circ \pi(x_1) = \pi(x_2)$, and apply Proposition 5.1 to $\pi_1 = \pi \circ f$ and $\pi_2 = \pi$. We get that there exists a unique homeomorphism $F : \mathcal{M} \rightarrow \mathcal{M}$ preserving the direct product structure such that $F(x_1) = x_2$ and $\pi \circ F = f \circ \pi$.

**Definition 5.2.** Let $\pi : \mathcal{M} \rightarrow \mathcal{X}$ be a splitting. We say that a homeomorphism $F : \mathcal{M} \rightarrow \mathcal{M}$ preserving the direct product structure is a lift of $f$ if $\pi \circ F = f \circ \pi$.

It follows from the above arguments that lifts of $f$ exist, and if $F_1$ and $F_2$ are two lifts, then $F_1^{-1}F_2$ and $F_1F_2^{-1}$ belong to $G$. 
It also follows that for every $g \in G$, and every lift $F$ of $f$, we have $F^{-1}gF \in G$. The map $g \mapsto F^{-1}gF$ is an automorphism of $G$. We say that it is induced by $f$. Any two automorphisms induced by $f$ on $G$ differ from each other by an inner automorphism.

**Proposition 5.2.** The group of deck transformations of a splitting of a connected and locally connected Smale space is finitely generated.

**Proof.** Let $\pi : \mathcal{M} \to \mathcal{X}$ be a splitting. Consider a finite covering $\mathcal{U}$ of $\mathcal{X}$ by open connected evenly covered by $\pi$ subsets. Let $\mathcal{U}_M$ be the union of the sets of connected components of $\pi^{-1}(U)$ for all $U \in \mathcal{U}$. Then $\mathcal{U}_M$ is a covering of $\mathcal{M}$. Since $\mathcal{M}$ is connected, every two elements $U, V \in \mathcal{U}_M$ are connected with each other by a chain of elements $U_0 = U, U_1, \ldots, U_n = V$ such that $U_i \cap U_{i+1} \neq \emptyset$. It follows that there exists a connected finite union $V$ of elements of $\mathcal{U}_M$ such that $\pi(V) = \mathcal{X}$. Note that $\overline{V}$ is compact.

Let $S$ be the set of elements $g \in G$ such that $g(V) \cap V \neq \emptyset$. It is finite, since the action of $G$ on $\mathcal{M}$ is proper.

Let $g \in G$ and $x_0 \in V$. Since $\mathcal{M}$ is connected and $\mathcal{M} = \bigcup_{g \in G} g(V)$, there exists a sequence $g_i \in G$, $i = 0, 1, \ldots, k$ such that $g_0 = 1$, $g_k = g$, and $g_i(V) \cap g_{i+1}(V) \neq \emptyset$ for all $i = 0, 1, \ldots, k-1$. Note that $g_i(V) \cap g_{i+1}(V) \neq \emptyset$ implies $V \cap g_i^{-1}g_{i+1}(V) \neq \emptyset$, hence $g_i^{-1}g_{i+1} \in S$. We see that $g = g_0^{-1}g_1^{-1}g_2 \cdots g_{k-1}^{-1}$ is a product of $k$ elements of $S$. \hfill $\square$

### 5.2. Splittable Smale spaces and hyperbolic graphs.

A connection between Smale spaces and Gromov hyperbolic graphs described in this subsection is a particular case of the theory of Cayley graphs of hyperbolic groupoids, described in [Nek11a]. Since the theory for Smale spaces is simpler than the general case, and in order to make our paper more self-contained, we describe them directly.

Let $(\mathcal{X}, f)$ be a Smale space with locally connected and connected space $\mathcal{X}$, and let $\pi : \mathcal{M} \to \mathcal{X}$ be a splitting. We denote by $[\cdot, \cdot]$ the direct product structures on $\mathcal{M}$ and $\mathcal{X}$. Let $G$ be the group of deck transformations of the splitting. Let $F : \mathcal{M} \to \mathcal{M}$ be a lift of $f$.

Let $d$ be a metric on $\mathcal{X}$ associated with the standard log-scale $\ell$. We will denote by $d_+$ and $d_-$ metrics on the stable and unstable leaves of $\mathcal{X}$ associated with the respective standard log-scales $\ell_+$ and $\ell_-$. We assume that exponents of the metrics $d$, $d_+$, and $d_-$ are equal. Then we have the following corollary of [Nek11a, Lemma 7.8], see also [Fri83].

**Proposition 5.3.** There exist constants $\epsilon, L > 1$ such that for every point $x \in \mathcal{X}$ and every rectangle $R$ contained in the $\epsilon$-neighborhood of $x$ restriction of $d$ onto $R$ is $L$-bi-Lipschitz equivalent to the metric given by

$$d_+(y_1, y_2) = d_+(\{[y_1, x], [y_2, x]\}) + d_-(\{[x, y_1], [x, y_2]\}).$$

Let $\epsilon > 0$ be such that it satisfies the conditions of Proposition 5.3 and for every $x \in \mathcal{X}$ the $\epsilon$-neighborhood of $x$ is evenly covered by $\pi$.

Define then $d_\mathcal{M}(x, y)$ as the infimum of the sum $\sum_{i=0}^{m-1} d(\pi(x_i), \pi(x_{i+1}))$ over all sequences $x_0, x_1, \ldots, x_m$ such that $x_0 = x$, $x_m = y$, and $d(\pi(x_i), \pi(x_{i+1})) < \epsilon$ for all $i = 0, 1, \ldots, m-1$.

Then $d_\mathcal{M}$ is a $G$-invariant metric on $\mathcal{M}$ such that $d_\mathcal{M}(x, y) = d(\pi(x), \pi(y))$ for all $x, y$ such that $d_\mathcal{M}(x, y) < \epsilon$. 

The map $\pi$ bijectively identifies the plaques $W_+(x)$ and $W_-(x)$ of $\mathcal{M}$ with their images $W_+^\pi(x)$ and $W_-^\pi(x)$, respectively. We get hence metrics $d_+$ and $d_-$ on $W_+(x)$ and $W_-(x)$, respectively. Then Proposition 5.3 holds when we replace $\mathcal{M}$ by $\mathcal{M}$ and $d$ by $d_\mathcal{M}$.

Let $R \subset \mathcal{M}$ be an open relatively compact rectangle such that $\bigcup_{g \in \mathcal{G}} g(R) = \mathcal{M}$. Let $W_+$ be a stable plaque of $\mathcal{M}$. Denote by $\Omega_n(W_+, R)$, for $n \in \mathbb{Z}$, the set of elements $g \in \mathcal{G}$ such that of $F^n(g(R))$ intersects $W_+$. Denote by $\Xi(W_+, R)$ the graph with the set of vertices $\bigcup_{n \in \mathbb{Z}} \Omega_n(W_+, R) \times \{n\}$ in which two vertices are connected by an edge if and only if they are either of the form $(g_1, n)$, $(g_2, n)$, where $g_1(R) \cap g_2(R) \neq \emptyset$, or of the form $(g_1, n)$, $(g_2, n + 1)$, where $g_1(R) \cap F(g_2(R)) \neq \emptyset$. In other words, we connect two vertices of $\Xi(W_+, R)$ if and only if they belong to the same or neighboring levels $\Omega_n(W_+, R)$ and the corresponding rectangles intersect.

**Theorem 5.4.** The graph $\Xi = \Xi(W_+, R)$ is Gromov hyperbolic. All paths of the form $(g_n, -n) \in \Xi$, $n \geq 0$, converge to one point $\omega \in \partial \mathcal{G}$. The map mapping the limit in $\partial \Xi$ of a path $(g_n, n)$, $n \geq 0$ to the limit of the intersections of $F^n(g_n(R))$ with $W_+$ induces a homeomorphism between $\partial \Xi \setminus \{\omega\}$ and $W_+$.

**Proof.** Consider two vertices $(g, 0)$ and $(h, 0)$. Let $m$ be the distance between them in $\Omega_0(W_+, R)$.

Let $(g_k, -k)$ and $(h_k, -k)$ for $k \geq 0$ be arbitrary paths in $\Xi$ such that $g_0 = g$ and $h_0 = h$.

There exists $\epsilon > 0$ such that for every $x \in \mathcal{M}$ there exist $g \in \mathcal{G}$ such that the ball of radius $\epsilon$ with center $x$ is contained in $g(R)$. It follows that for every $m \in \mathbb{N}$ there exists $N_m > 0$ such that for any path $(a_0, 0), (a_1, 0), \ldots, (a_m, 0)$ of length $m$ in $\Omega_0(W_+, R)$ there exists $g \in \mathcal{G}$ such that $F^m(a_0(R)) \cup \cdots \cup F^m(a_m(R)) \cap W_+ \subset g(R) \cap W_+$. It follows that $(g_{N_m}, -N_m)$ and $(h_{N_m}, -N_m)$ are on distance at most 2 in $\Omega_{-N_m}(W_+, R)$.

It follows now from [Nek11a] Theorem 2.10 that the graph $\Xi$ is Gromov hyperbolic, that the level function $(g(R), n) \mapsto n$ is a Busemann function of a point $\omega \in \partial \mathcal{G}$, and that every path $(g_n, n)$ for $n \geq 0$ converges to a point of $\partial \Xi \setminus \omega$, whereas every path of the form $(g_n, -n)$, $n \geq 0$, converges to $\omega$.

**Lemma 5.5.** Every point of $\partial \Xi \setminus \omega$ is the limit of a sequence of the form $(g_n, n)$.

**Proof.** Note that since $(g, n) \mapsto n$ is a Busemann function associated with $\omega \in \partial \mathcal{G}$, every point $\xi \in \partial \Xi \setminus \omega$ is the limit of a sequence of the form $(g_n, n)$ (which is not necessarily a path). For every $n \geq 0$ there exists a path $(h_{n, k}, k)$, $k \leq n$, such that $h_{n, n_l} = g_n$. All these paths converge to $\omega$, and by the above arguments, for any $n_1, n_2$, distance from $(h_{n_1, k}, k)$ to $(h_{n_2, k}, k)$ is not more than 2 for all $k$ smaller than some $k(n_1, n_2)$. Moreover, $k(n_1, n_2) \to \infty$ as $n_1, n_2 \to \infty$. It follows then by compactness arguments (since $\Xi$ has bounded valency) that there exists a path $(h_{n, n}, n \geq 0$, converging to $\xi$. \qed

Let $(g_n, n)$, for $n \geq 0$, be a path in $\Xi$. The sets $V_n = F^n(g_n(R)) \cap W_+$ are compact, their diameters decrease exponentially, and we have $V_n \cap V_{n+1} \neq \emptyset$ for every $n$. It follows that the sequence $V_n$ converges (in the Hausdorff metric) to a point $x \in W_+$. Let us show that the map $\Lambda : \lim_{n \to \infty} (g_n, n) \mapsto \lim_{n \to \infty} F^n(g_n(R))$ is a homeomorphism between $\partial \Xi \setminus \omega$ and $W_+$.

The arguments basically repeat the proof of [Nek11a] Theorem 6.9]. Let us show that the map is well defined. If $(g_n, n)$ and $(h_n, n)$ converge to the same limit
in \( \partial \Xi \), then the distance between \( g_n \) and \( h_n \) in \( \Omega_n(W_+, R) \) is uniformly bounded. But this implies that the Hausdorff distance between \( F^n(g_n(R)) \) and \( F^n(h_n(R)) \) is exponentially decreasing, hence \( \lim_{n \to \infty} F^n(g_n(R)) = \lim_{n \to \infty} F^n(h_n(R)) \). The same argument shows that the map \( \Lambda \) is continuous, since if \( \xi_1 \) and \( \xi_2 \) are close to each other, then the sequences \( (g_n, n) \) and \( (h_n, n) \) are close to each other for an initial interval \( n = 0, \ldots, L \), where \( L \) is big but then the limits \( \lim_{n \to \infty} F^n(g_n(R)) \) and \( \lim_{n \to \infty} F^n(h_n(R)) \) are close to each other.

The map \( \Lambda \) is onto, since for every point \( x \in W_+ \) there exists a path \( (g_n, n) \) defined by the condition \( F^n(g_n(R)) \ni x \).

Using Lebesgue’s covering lemma, we show that if \( x \) and \( y \) are close to each other, then there exists a sequence \( (g_n, n) \) such that \( F^n(g_n(R)) \ni \{x, y\} \) for all \( n = 0, \ldots, L \), where \( L \) is big. This shows that \( \Lambda^{-1} \) exists and is continuous. \( \square \)

Suppose now that the map \( F : \mathcal{M} \to \mathcal{M} \) has a fixed point \( x_0 \). Let \( \phi : G \to G \) be the automorphism defined by the condition \( F(g(x_0)) = \phi(g)(x_0) \). Let \( W_+ \) and \( W_- \) be the stable and the unstable plaques of \( \mathcal{M} \) containing \( x_0 \). Let \( R, \Omega_n(W_+, R) \), and \( \Xi(W_+, R) \) be as above. We assume that \( R \) is connected and \( x_0 \in R \).

Note that \( F^n(g(R)) \cap W_+ \neq \emptyset \) is equivalent to \( g(R) \cap F^{-n}(W_+) = g(R) \cap W_+ \neq \emptyset \). It follows that the set \( \Omega_n(W_+, R) \) does not depend on \( n \).

The graph \( \Xi(W_+, R) \) is isomorphic then to the graph with the set of vertices \( \Omega_0(W_+, R) \times Z \) in which two vertices are connected by an edge if and only if they are either of the form \((g_1, n)\) and \((g_2, n)\), where \( g_1, g_2 \in \Omega_0(W_+, R) \) and \( g_1(R) \cap g_2(R) \neq \emptyset \), or of the form \((g_1, n)\) and \((g_2, n+1)\), where \( g_1, g_2 \in \Omega_0(W_+, R) \) and \( F^n(g_1(R)) \cap F^{n+1}(g_2(R)) \neq \emptyset \), which is equivalent to \( g_1(R) \cap \phi(g_2)(F(R)) \neq \emptyset \). Note that \( (g, n) \mapsto (g, n+1) \) is an automorphism of \( \Xi(W_+, R) \).

Let \( A \subset G \) be a finite set containing the identity, and let \( S \) be a finite generating set of \( G \). We assume that \( S \) contains all elements \( g \in G \) such that \( R \cap g(R) \neq \emptyset \) or \( R \cap g(F(R)) \neq \emptyset \) and that \( A \subset S \).

Let \( \Omega'_0 \subset G \) be any set such that \( \Omega_0(W_+, R) \subset \Omega'_0 \subset \Omega_0(W_+, R)A \).

Denote then by \( \Xi' \) the graph with the set of vertices \( \Omega'_0 \times Z \) with edges of two kinds: vertical and horizontal. The horizontal edges connect two vertices \((g_1, n), (g_2, n)\) if and only if \( g_1^{-1}g_2 \in S \). The vertical edges connect a vertex \((g_1, n)\) to a vertex \((g_2, n+1)\) if and only if \( g_1^{-1}\phi(g_2) \in S \).

Note that if \( g_1(R) \cap g_2(R) \neq \emptyset \), then \( R \cap g_1^{-1}g_2(R) \neq \emptyset \). If \( g_1(R) \cap F(g_2(R)) \neq \emptyset \), then \( g_1(R) \cap \phi(g_2)(F(R)) \neq \emptyset \), hence \( R \cap g_1^{-1}\phi(g_2)(F(R)) \neq \emptyset \). It follows that \( \Xi(W_+, R) \) is a sub-graph of \( \Xi' \).

**Proposition 5.6.** The inclusion \( \Xi(W_+, R) \hookrightarrow \Xi' \) is a quasi-isometry.

**Proof.** Let us prove at first the following lemmas.

**Lemma 5.7.** There exists \( n_1 > 0 \) such that \( \phi^{-n_1}(\Omega_0(W_+, R)) \subset \Omega_0(W_+, R) \).

For every such \( n_1 \) there exists \( D_{n_1} \) such that distance from \( (g, n) \) to \( (\phi^{-n_1}(g), n + n_1) \) in \( \Xi(W_+, R) \) is less than \( D_{n_1} \).

**Proof.** By Lebesgue’s covering lemma, there exists \( \epsilon > 0 \) such that for every \( x \in \mathcal{M} \) there exists \( g \in G \) such that \( \epsilon \)-neighborhood of \( x \) is contained in \( g(R) \). It follows that if distance from \( x \) to \( W_+ \) is less than \( \epsilon \), then there exists \( g \in \Omega_0(W_+, R) \) such that \( x \in g(R) \).

There exists an upper bound (equal to the diameter of \( R \)) on the distance from \( g(x_0) \) to \( W_+ \) for all \( g \in \Omega_0(W_+, R) \). Consequently, there exists \( n_1 > 0 \) such that \( \phi^{-n_1}(\Omega_0(W_+, R)) \subset \Omega_0(W_+, R) \).
Let us prove the second part of the lemma. Let \((g, n) \in \Xi(W_+, R)\), and let \(x \in g(R) \cap W_+\). Choose for \(k = 1, \ldots, n_1\), \(h_k \in \Omega_0(W_+, R)\) such that \(F^{-k}(x) \in h_k(R)\). Then \(F^{-1}(x) \in h_1(R)\) and \(x \in g(R)\), hence \(F(h_1(R)) \cap g(R) \neq \emptyset\), which implies that \((g, n)\) is connected to \((h_1, n + 1)\). Similarly, \(F^{-(k+1)}(x) \in h_{k+1}(R)\), hence \(F(h_{k+1}(R)) \cap h_k(R) \neq \emptyset\), so that \((h_k, n + k)\) is connected to \((h_{k+1}, n + k + 1)\). We have \(g(x_0) \in g(R)\), hence \(F^{-n_1}(x) \in h_{n_1}(R)\) and \(F^{-n_1}(x), \phi^{-n_1}(g)(x_0) \in F^{-n_1}(g(R)) = \phi^{-n_1}(g)(F^{-n_1}(R))\). The set \(F^{-n_1}(g(R))\) is connected, hence there exists a path \(p_1, f_2, \ldots, f_m\) in \(\Omega_0(W_+, R) \times \{n + 1\}\) connecting \((h_{n_1}, n + n_1)\) to \((\phi^{-n_1}(g), n + n_1)\). Since \(F^{-n_1}(R)\) is relatively compact, there exists a uniform bound \(M\) such that we may assume that \(m \leq M\). It follows that the distance in \(\Xi(W_+, R)\) from \((g, n)\) to \((\phi^{-n_1}(g), n + n_1)\) is not more than \(n_1 + m - 1\).

**Lemma 5.8.** For every finite set \(B \subset G\) there exists \(D > 0\) such that if \(g_1^{-1}g_2 \in B\) for \(g_1, g_2 \in \Omega_0(W_+, R)\), then distance between \((g_1, n)\) and \((g_2, n)\) in \(\Xi(W_+, R)\) is not greater than \(D\).

**Proof.** Let \(R_B\) be a compact connected rectangle of \(M\) containing \(B(x_0)\). Note that it follows from Proposition 5.3 that there exists a uniform upper bound on the \(d_\infty\)-diameter of the unstable plaques of \(R_B\). Then it is also a uniform upper bound on the \(d_\infty\)-distance from \(W_+\) of a point of \(g(R_B)\) for \(g \in \Omega_0(W_+, R)\).

It follows that for every \(\epsilon > 0\) there exists \(n_2 > 0\) such that for every \(g \in \Omega_0(W_+, R)\) the set \(F^{-n_2}(g(R_B))\) belongs to the \(\epsilon\)-neighborhood of \(W_+\), hence (if \(\epsilon\) is small enough) it is covered by the sets \(h(R)\) for \(h \in \Omega_0(W_+, R)\). Since \(F^{-n_2}(g(R_B))\) is connected, for every two points \(x, y \in g(R_B)\) there exists a sequence \(h_1, h_2, \ldots, h_m \in \Omega_0(W_+, R)\) such that \(F^{-n_2}(x) \in h_1(R), F^{-n_2}(y) \in h_m(R), h_i(R) \cap h_{i+1}(R) \neq \emptyset\) for all \(i = 1, \ldots, m - 1\), and \(h_1\) are pairwise different. Since \(F^{-n_2}(g(R_B)) = \phi^{-n_2}(g)(F^{-n_2}(R_B))\) belong to the \(G\)-orbit of \(F^{-n_2}(R_B)\), there exists a uniform upper bound \(M(n_2)\) on the length \(m - 1\) of the corresponding path \(h_1, \ldots, h_m\) in \(\Omega_0(W_+, R) \times \{0\}\). We can choose \(n_2\) bigger than the number \(n_1\) from Lemma 5.7.

Let \(g_1, g_2 \in \Omega_0(W_+, R)\) be such that \(g_1^{-1}g_2 \in B\). Since \(g_1^{-1}g_2 \in B, g_1(x_0), g_2(x_0) \in g_1(R_B)\). It follows that there exists a path \(h_1, \ldots, h_m \in \Omega_0(W_+, R)\) such that \(m < M\), and \(F^{-n_2}(g_1(x_0)) \in h_1(R), F^{-n_2}(g_2(x_0)) \in h_m(R)\). The last two conditions are equivalent to \(\phi^{-n_2}(g_1)(x_0) \in h_1(R)\) and \(\phi^{-n_2}(g_2)(x_0) \in h_m(R)\), which imply that \(\phi^{-n_2}(g_1), 0\) and \(\phi^{-n_2}(g_2), 0\) are connected to \((h_1, 0)\) and \((h_m, 0)\), respectively, by horizontal edges. By Lemma 5.7 we have a uniform bound on the distances from \((g_1, n)\) to \((\phi^{-n_2}(g_1), n + n_1)\) and from \((g_2, n)\) to \((\phi^{-n_2}(g_2), n + n_1)\), which finishes the proof.

The proof of the following lemma is analogous.

**Lemma 5.9.** For every finite set \(B \subset G\) there exists \(D > 0\) such that if \(g_1^{-1}\phi(g_2) \in B\) for \(g_1, g_2 \in \Omega_0(W_+, R)\), then the distance between \((g_1, n)\) and \((g_2, n + 1)\) in \(\Xi(W_+, R)\) is not greater than \(D\).

Let us go back to proving Proposition 5.6. The image of \(\Xi(W_+, R)\) under the inclusion map is a 1-net in \(\Xi'\). Distance between vertices in \(\Xi(W_+, R)\) is not less than the distance between them in \(\Xi'\).

Let us show that there exists a constant \(D > 1\) such that distance between \((g_1, n_1), (g_2, n_2)\) in \(\Xi(W_+, R)\) is not more than \(D\) times the distance from \((g_1, n_1)\)
to \((g_2, n_2)\) in \(\Xi'\). Let \((g_1, n_1) = v_0, v_1, \ldots, v_n = (g_2, n_2)\) be a geodesic path in \(\Xi'\). Since \(\Xi(W_+, R)\) is a net in \(\Xi'\), there exists a constant \(C > 1\) such that every such geodesic path can be replaced by a path \((g_1, n_1), v_1', \ldots, v_{n'-1}', (g_2, n_2)\), where \(v_i' \in \Xi(W_+, R)\), and distance from \(v_i'\) to \(v_{i-1}'\) in \(\Xi'\) is bounded from above by \(C\).

Moreover, we may assume that each \(v_i'\) belongs to the same level \(\Omega_n\) as \(v_i\). Then \(v_i'\) and \(v_{i+1}'\) either belong to one level, or to two neighboring levels. Then Lemmas 5.5 and 5.9 finish the proof.

**Definition 5.3.** Let \(G\) be the group of deck transformations of the splitting \(\pi : \mathcal{M} \rightarrow \mathcal{X}\), and let \(F : \mathcal{M} \rightarrow \mathcal{M}\) be a lift of \(f\) with a fixed point \(x_0\). A set \(\Sigma \subset G\) is a coarse stable (resp. unstable) plaque if the stable plaque \(W_+(x_0)\) (resp. unstable plaque \(W_-(x_0)\)) and the set \(\Sigma(x_0)\) are on finite Hausdorff distance from each other.

Recall that two subsets \(A_1, A_2\) of a metric space \((X, d)\) are on a finite Hausdorff distance from each other if there exists \(D > 0\) such that for every \(x \in A_1\) there exists \(y \in A_2\), and for every \(y \in A_2\) there exists \(x \in A_1\) such that \(d(x, y) < D\).

**Theorem 5.10.** Let \((\mathcal{X}, f)\) be a connected and locally connected Smale space. Suppose that there exists a splitting \(\pi : \mathcal{M} \rightarrow \mathcal{X}\) and a lift \(F : \mathcal{M} \rightarrow \mathcal{M}\) of \(f\) with a fixed point \(x_0\). Let \(\phi\) be the associated automorphism of \(G\), and let \(\Sigma_+\) and \(\Sigma_-\) be coarse stable and unstable plaques of \(x_0\). Then \((\mathcal{X}, f)\) is uniquely determined, up to topological conjugacy by the quadruple \((G, \phi, \Sigma_+, \Sigma_-)\).

**Proof.** The dynamical system \((\mathcal{X}, f)\) is uniquely determined by the \(G\)-space \(\mathcal{M}\) and the map \(F : \mathcal{M} \rightarrow \mathcal{M}\). The group \(G\) acts on the plaques \(W_+\) and \(W_-\) by the actions

\[
g : x \mapsto [g(x), x], \quad g : x \mapsto [x, g(x)],
\]

respectively. The action of \(G\) on \(\mathcal{M} \cong W_+ \times W_-\) is reconstructed from these actions by the formula

\[g(x) = [[g(x), x], [x, g(x)]]\]

Similarly, the map \(F : \mathcal{M} \rightarrow \mathcal{M}\) is determined by the action of \(F\) on \(W_+\) and \(W_-\), since

\[F([x, y]) = [F(x), F(y)].\]

Consequently, it is enough to show that the quadruple \((G, \phi, \Sigma_+, \Sigma_-)\) uniquely determines the dynamical systems \((W_+, G)\), \((W_+, F)\), \((W_-, G)\), and \((W_-, F)\), up to topological conjugacy. Let us prove that the triple \((G, \phi, \Sigma_+)\) uniquely determines the dynamical systems \((W_+, G)\) and \((W_+, F)\). The same proof will show that \((G, \phi, \Sigma_-)\) uniquely determines \((W_-, G)\) and \((W_-, F)\).

Let \(R \subset \mathcal{M}\) be a relatively compact open rectangle such that \(x_0 \in R\) and \(\bigcup_{g \in G} g(R) = \mathcal{M}\). Let \(\Omega_0(W_+, R)\) be, as before, the set of elements \(g \in G\) such that \(g(R) \cap W_+ \neq \emptyset\).

For a set \(\Sigma \subset G\) and a finite generating set \(S\) of \(G\), denote by \(\Xi(\Sigma, S)\) the graph with the set of vertices \(\Sigma \times \mathbb{Z}\) in which two vertices are adjacent either if they are of the form \((g, n)\) and \((gs, n)\) for \(g, gs \in \Sigma\) and \(s \in S\), or of the form \((g, n)\) and \((\phi^{-1}(gs), n+1)\) for \(g, \phi^{-1}(gs) \in \Sigma\) and \(s \in S\). Note that the map \((g, n) \mapsto (g, n+1)\) is an automorphism of \(\Xi(\Sigma, S)\).

If \(A\) is big enough, then \(\Sigma_+ A\) contains \(\Omega_0(W_+, R)\). Then by Proposition 5.6, the identical embedding \(\Xi(W_+, R) \rightarrow \Xi(\Sigma_+ A, S)\) is a quasi-isometry, provided \(S\) is big enough. It follows then from Theorem 5.2 that \(\Xi(\Sigma_+ A, S)\) is Gromov hyperbolic, and that the boundary of \(\Xi(\Sigma_+ A, S)\) minus the common limit \(\omega\) of quasi-geodesic
paths of the form \((g_n, -n)\), \(n \geq 1\), is homeomorphic to \(W_+\). Moreover, it follows directly from Theorem 5.4 that the natural homeomorphism \(\Phi : \partial \Xi(\Sigma_+, A, S) \setminus \omega \to W_+\) maps the limit of a sequence \((g_n, n) \in \Xi(\Sigma_+, A, S)\) to the limit of the sequence 

\[ F^n(g_n(x_0)), x_0 = [\phi^n(g_n)(x_0), x_0] \in W_+ \]

Consequently, the homeomorphism \(\Phi\) conjugates \(F : W_+ \to W_+\) with the map on the boundary of \(\Xi(\Sigma_+, A, S)\) induced by the automorphism \((g, n) \mapsto (g, n + 1)\). This shows that the dynamical system \((F, W_+)\) is uniquely determined by \((G, \phi, \Sigma_+)\).

It remains to show that for every \(g \in G\) the homeomorphism \(g : x \mapsto [g(x), x_0]\) of \(W_+\) is uniquely determined by \((G, \phi, \Sigma_+)\) and \(g\).

Let \(\xi\) be the limit of a sequence \((g_n, n) \in \Xi(\Sigma_+, A, S)\), where \(s_n = g_n^{-1}\phi(g_{n+1}) \in S\) for all \(n \geq 0\). Note that every point of \(\partial \Xi(\Sigma_+, A, S)\) can be represented in this way, provided \(S\) is big enough (see Theorem 5.4).

There exists \(\epsilon > 0\) such that for every \(x \in M\) there exists \(g \in G\) such that the \(\epsilon\)-neighborhood of \(x\) is contained in \(g(R)\). Let \(x \in W_+\). Choose for every \(n \geq 0\) an element \(g_n \in G\) such that the \(\epsilon\)-neighborhood of \(F^{-n}(x)\) is contained in \(g_n(R)\). Then \(x\) is contained in \(F^n(g_n(R))\). In particular, \(F^n(g_n(R)) \cap F^{n+1}(g_{n+1}(R)) \neq \emptyset\), i.e, the sequence \((g_n, n)\) is a path in \(\Xi(W_+, R)\), and its limit in \(\partial \Xi(W_+, R)\) is mapped by the natural homeomorphism to \(x\).

The rectangles \(gF^n(g_n(R))\) contain \(g(x)\) for all \(n\). Since \(F\) is expanding in the unstable direction, the sets \(gF^n(g_n(R))\) intersects \(W_+\) (i.e., \(\phi^{-n}(g)g_n \in \Omega_0(W_+, R)\)) for all \(n\) big enough.

The limit of the intersections of \(gF^n(g_n(R))\) with \(W_+\) is equal to \([x_0, g(x)]\). It follows that \((\phi^{-n}(g)g_n, n)\), where \(n\) is big enough, is a path in \(\Xi(W_+, R)\) converging to the point of \(\partial \Xi(W_+, R)\) corresponding to \([x_0, g(x)]\) in \(W_+\), i.e., to the image of \(x\) under the action of \(g\) on \(W_+\).

Note that left multiplication by \(g\) preserves the distances between the vertices of the graph \(\Xi(\Sigma_+, A, S)\) (when the images of the vertices belong to the graph). It also follows from the classical properties of Gromov hyperbolic graphs that there exists a constant \(\Delta_1\) such that if two paths \((g_n, n)\) and \((h_n, n)\) of \(\Xi(\Sigma_+, A, S)\) converge to the same point of the boundary, then distance between \((g_n, n)\) and \((h_n, n)\) is less than \(\Delta_1\) for all \(n\) big enough.

It follows that the action of \(g\) on \(W_+\) can be modeled on the boundary of \(\Xi(\Sigma_+, A, S)\) by the following rule. Take a path \((g_n, n) \in \Xi(\Sigma_+, A, S)\) converging to a point \(\xi \in \partial \Xi(\Sigma_+, A, S)\). If \((gg_n, n)\) for \(n\) big enough belong to \(\Xi(\Sigma_+, A, S)\), then its limit is \(g(\xi)\). Since \(\Xi(W_+, R) \subset \Xi(\Sigma_+, A, S)\), this rule will determine the action of \(g\) on \(\partial \Xi(\Sigma_+, A, S) \setminus \{\omega\}\).

**Theorem 5.11.** Let \((X_1, f_1)\) and \((X_2, f_2)\) be connected and locally connected Smale spaces. Suppose that they exist fixed points of \(f_i\) and splittings \(\pi_i : M_i \to X_i\). Let \(G_i\) be the groups of deck transformations of the splittings. Let \(F_i\) be lifts of \(f_i\), with fixed points \(x_i \in M_i\). If there exists a continuous map \(\Phi : M_1 \to M_2\) and an isomorphism \(\Psi : G_1 \to G_2\) such that \(\Phi(x_1) = x_2\), and

\[ \Phi(F_1(x)) = F_2(\Phi(x)), \quad \Phi(F_1(g(x))) = F_2(\psi(g)(\Phi(x))) \]

for all \(x \in M_1\) and \(g \in G_1\), then \((X_1, f_1)\) and \((X_2, f_2)\) are topologically conjugate.

**Proof.** The map \(\Phi\) is proper as an equivariant map between two proper actions (see, for instance [Nek08, Lemma 5.2]).
Let $U$ be a compact neighborhood of $x_2 \in M_2$. Then $\bigcup_{n \geq 1} \bigcap_{k \geq n} F^k_2(U)$ is equal to the unstable plaque $W_-(x_2)$ in $M_2$. Similarly,

$$\bigcup_{n \geq 1} \bigcap_{k \geq n} F^k_2(\Phi^{-1}(U)) = \Phi^{-1} \left( \bigcup_{n \geq 1} \bigcap_{k \geq n} F^k_2(U) \right)$$

is equal to the unstable plaque $W_-(x_1)$ in $M_1$. It follows that $\Phi^{-1}(W_-(x_2)) = W_-(x_1)$. Similarly, $\Phi^{-1}(W_+(x_2)) = W_+(x_1)$.

Let $K_2$ be a compact subset of $M_2$ such that $K_2$ and $K_1 = \Phi^{-1}(K)$ are $G_i$-transversals. They exist, since the actions of $G_i$ are co-compact, proper, and the map $\Phi$ is continuous and proper.

Then $g_2(K_2) \cap W_-(x_2) \neq \emptyset$ for $g_2 \in G_2$ is equivalent to $\psi^{-1}(g_2)(K_1) \cap W_-(x_1) \neq \emptyset$. The same is true for the stable plaques $W_+(x_1)$ and $W_+(x_2)$. It follows then from Theorem 5.10 that $(X_1, f_1)$ and $(X_2, f_2)$ are topologically conjugate. \hfill \Box

6. Smale spaces with virtually nilpotent splitting

Let $L$ be a simply connected nilpotent Lie group. Let $G$ be a finitely generated subgroup of $\text{Aut } L \rtimes L$ such that the action of $G$ on $L$ is free, proper, and co-compact. Here we identify the elements of $A$ with the transformations $g \mapsto \alpha(g) \cdot h$ of $L$, where $\alpha \in \text{Aut } L$ and $h \in L$.

Let $F \in \text{Aut } L$ be a hyperbolic automorphism of $L$ (i.e., such that its differential $DF$ at the identity of $L$ has no eigenvalues of absolute value one). Then $F$ induces an automorphism $\phi$ of $\text{Aut } \rtimes L$ by conjugation. Suppose that $G$ is invariant under this automorphism. Then $F$ induces an Anosov homeomorphism $f : G/L \to G/L$. Such homeomorphisms are called hyperbolic infra-nilmanifold automorphisms.

The aim of this section is to prove the following description of locally connected Smale spaces that have a splitting with a virtually nilpotent group of deck transformation.

**Theorem 6.1.** Let $(X, f)$ be a Smale space such that $X$ is connected and locally connected, and there exists a splitting $\pi : M \to X$ with a virtually nilpotent group of deck transformations. Then $(X, f)$ is topologically conjugate to a hyperbolic infra-nilmanifold automorphism.

**Proof.** Let $(X, f)$ satisfy conditions of the theorem. Let us assume at first that the group $G$ of deck transformations is nilpotent and torsion free.

Let $F$ be a lift of $f$, and let $F(x_0) = x_1$. Then the map $g \mapsto \phi(g)$ defined by $F(g(x_0)) = \phi(g)(x_1)$ is an automorphism of $G$.

Denote by $Z(G)$ the center of $G$, i.e., the set of elements of $G$ that commute with every element of $G$.

The group $Z(G)$ is obviously abelian and torsion free. It is finitely generated, since all subgroups of a finitely generated nilpotent group are finitely generated (see [Rob96, 5.2.17]). Consequently, $Z(G)$ is isomorphic to $\mathbb{Z}^d$ for some $d$.

**Lemma 6.2.** Let $g \in Z(G)$. There exist positive constants $D_-$ and $D_+$ such that for every stable (resp. unstable) plaque $V$ of $M$ and any $x \in V$, $y \in g(V)$ we have $d_-(x, [x, y]) \leq D_-$ (resp. $d_+(x, [y, x]) \leq D_+$).

**Proof.** Let us prove the lemma for stable plaques. Note that $[x, y]$ is equal to the intersection of $g(V)$ with $W_-(x)$, and so does not depend on the choice of $y \in g(V)$. Therefore, it is enough to show that $d_-(x, [x, g(x)])$ is bounded for all $x \in M$, see
For every finite set $\Lambda$, Proposition 6.4.

Let us prove the first inequality. The second is proved in the same way.

**Proof.**

Denote for $g \in Z(G)$

$$D_+(g) = \sup_{x \in \mathcal{M}} d_-(x, [x, g(x)]), \quad D_+(g) = \sup_{x \in \mathcal{M}} d_+(x, [g(x), x]),$$

which are finite by Lemma 6.2. Note that we obviously have

$$D_+(g_{1}g_{2}) \leq D_+(g_1) + D_+(g_2), \quad D_-(g_{1}g_{2}) \leq D_-(g_1) + D_-(g_2)$$

for all $g_1, g_2 \in Z(G)$.

Let $\lambda \in (0, 1)$ and $C > 1$ be such that for any two stably (resp. unstably) equivalent points $x, y \in X$ we have

$$d_+(f^n(x), f^n(y)) \leq C\lambda^n d_+(x, y)$$

(resp. $d_-(f^{-n}(x), f^{-n}(y)) \leq C\lambda^n d_-(x, y)$) for all $n \geq 0$. Then the same estimates will hold for $F$ and $x, y \in \mathcal{M}$ belonging to one stable (resp. unstable) plaque.

**Proposition 6.3.** For every $g \in Z(G)$ and $n \geq 0$ we have

$$D_+(\phi^n(g)) \leq C\lambda^n D_+(g), \quad D_-(\phi^{-n}(g)) \leq C\lambda^n D_-(g).$$

The center $Z(G)$ is characteristic (i.e., invariant under automorphisms of $G$), hence $\phi(Z(G)) = Z(G)$.

**Proof.** Let us prove the first inequality. The second is proved in the same way.

Let $V$ be an unstable plaque of $\mathcal{M}$, and let $x \in V$ and $y \in \phi^n(g)(V)$ be such that $x$ and $y$ belong to the same stable plaque. It is enough to prove that $d_+(x, y) \leq C\lambda^n D_+(g)$.

The points $F^{-n}(x)$ and $F^{-n}(y)$ belong to one stable plaque, and $F^{-n}(x) \in F^{-n}(V), \quad F^{-n}(y) \in F^{-n}(\phi^n(g)(V)) = g(F^{-n}(V))$, hence $d_+(F^{-n}(x), F^{-n}(y)) \leq D_+(g)$. But this implies $d_+(x, y) \leq C\lambda^n d_+(x, y)$. 

**Proposition 6.4.** For every finite set $S \subset Z(G)$ there exists a constant $D_S > 0$ satisfying the following condition. For every finite set $A \subset Z(G)$ there exists $n_0$ such...
that for all \( n \geq n_0 \), \( g_1, g_2 \in \phi^n(A) \phi^{n-1}(S) \phi^{n-2}(S) \cdots \phi(S)S \), and every unstable plaque \( V \) we have
\[
d_+(x, [y, z]) < D_S
\]
for all \( x \in g_1(V) \) and \( y \in g_2(V) \).

**Proof.** Let \( \Delta_S \) and \( \Delta_A \) be upper bounds on \( D_+(g) \) for \( g \in S \) and \( g \in A \), respectively. Then, by Proposition 6.3 we have, for all \( h \in A, g_i \in S \), and \( n \) big enough,
\[
D_+(\phi^n(h)\phi^{n-1}(g_1)\cdots\phi(g_{n-1})g_n) \leq 
C\lambda^n \Delta_A + C(\lambda^{n-1} + \cdots + \lambda + 1)\Delta_S < 1 + \frac{C\Delta_S}{1-\lambda}.
\]
It follows that we can take \( D_S = 2 + \frac{2C\Delta_S}{1-\lambda} \).

**Proposition 6.5.** The automorphism \( \phi \) of \( Z(G) \cong \mathbb{Z}^d \) is hyperbolic, i.e., has no eigenvalues of absolute value 1.

**Proof.** Suppose that on the contrary, there exists an eigenvalue \( \cos \alpha + i \sin \alpha \) of \( \phi \) of absolute value 1. Suppose at first that \( \alpha \not\in \pi \cdot \mathbb{Z} \). Then there exists a two-dimensional subspace \( L \leq \mathbb{R}^d \) and a Euclidean structure on it such that \( \phi \) acts on \( L \) as a rotation by the angle \( \alpha \). Denote \( K = \{(x_i)_{i=1}^d \in \mathbb{R}^d : |x_i| < 1\} \), and let \( S \) be the set of elements \( g \in Z(G) = \mathbb{Z}^d \) such that \( \phi(K) \cap (K + g) \neq \emptyset \) or \( \phi^{-1}(K) \cap (K + g) \neq \emptyset \). The set \( S \) is obviously finite.

Let \( R > 0 \) be arbitrary, and consider the circle \( \gamma \) of radius \( R \) in \( L \) with center in the origin. Then \( \phi(\gamma) = \gamma \). Let \( A_R \) be the set of elements \( g \in Z(G) \) such that \( K + g \cap \gamma \neq \emptyset \). It is finite and non-empty. Note that union of the sets \( A_R \) for all \( R > 0 \) is infinite.

Let \( h \) be an arbitrary element of \( A_R \), and let \( x \in K + h \cap \gamma \). Then \( \phi^{-1}(x) \in \gamma \), and there exists \( g \in \mathbb{Z}^d \) such that \( \phi^{-1}(x) \in K + g \). Then \( g \in A_R \), and \( x \in \phi(K) \cap K + h \). It follows that \( K + h - \phi(g) \cap \phi(K) \neq \emptyset \), so that \( h - \phi(g) \in S \). We see that \( h = \phi(h) + (h - \phi(g)) \in \phi(A_R) + S \). We have proved that \( A_R \subset \phi(A_R) + S \).

It is proved in the same way that \( A_R \subset \phi^{-1}(A_R) + S \). By induction we conclude that
\[
A_R \subset \phi^n(A_R) + \phi^{n-1}(S) + \cdots + \phi(S) + S
\]
and
\[
A_R \subset \phi^{-n}(A_R) + \phi^{-(n-1)}(S) + \cdots + \phi^{-1}(S) + S
\]
for all \( n \geq 1 \).

Fix an arbitrary point \( x_0 \in M \). Since \( \phi^n(A_R) + \phi^{n-1}(S) + \cdots + \phi(S) + S \supset A_R \) for all \( n \), it follows from Proposition 6.4 that there exists \( D_S > 0 \), not depending on \( R \), such that \( d_+(x_0, [g(x_0), x_0]) < D_S \) and \( d_-(x_0, [g(x_0), x_0]) < D_S \) for all \( g \in A_R \). It follows that \( g(x_0) \) belongs to the rectangle \([B_+, B_-] \), where \( B_\pm \) are the balls of radius \( D_S \) with center in \( x_0 \) in the corresponding plaque containing \( x_0 \). Note that the set \( \{g \in G : g(x_0) \in [B_+, B_-]\} \) is finite, does not depend on \( R \), and contains \( A_R \). But this is a contradiction.

The case when the eigenvalue is equal to \( \pm 1 \) is similar (with one-dimensional space \( L \)).

Let \( E_+ \) (resp. \( E_- \)) be the sum of the root subspaces of \( \mathbb{R}^d \) of the eigenvalues \( \lambda \) of \( \phi \) such that \( |\lambda| < 1 \) (resp. \( |\lambda| > 1 \)). We have \( \mathbb{R}^d = E_+ \oplus E_- \). Denote by \( P_+ \) and \( P_- = 1 - P_+ \) the projections onto \( E_+ \) and \( E_- \), respectively.
Denote $K = \{ (x_i)_{i=1}^d \in \mathbb{R}^d : |x_i| < 1 \}$. Let $S \subset Z(G)$ be a finite set containing all elements $g \in Z(G)$ such that $K + g \cap (\phi(K) \cup \phi^{-1}(K)) \neq \emptyset$.

**Proposition 6.6.** For every point $x \in E_+$ there exists a sequence $g_i \in S$, $i = 1, 2, \ldots$, and an element $g_0 \in Z(G)$ such that

$$x = \lim_{n \to \infty} P_+ (\phi^n(g_n) + \phi^{n-1}(g_{n-1}) + \cdots + \phi(g_1) + g_0).$$

There exists a finite set $N \subset Z(G)$ such that an equality

$$\lim_{n \to \infty} P_+ (\phi^n(g_n) + \phi^{n-1}(g_{n-1}) + \cdots + \phi(g_1) + g_0) = \lim_{n \to \infty} P_+ (\phi^n(g'_n) + \phi^{n-1}(g'_{n-1}) + \cdots + \phi(g'_1) + g'_0)$$

holds for $g_i, g'_i \in S$, $i \geq 1$, and $g_0, g'_0 \in Z(G)$ if and only if there exists a sequence $h_n \in N$ such that

$$\phi^n(g_n) + \phi^{n-1}(g_{n-1}) + \cdots + \phi(g_1) + g_0 = \phi^n(h_n + g_n) + \phi^{n-1}(g_{n-1}) + \cdots + \phi(g_1) + g_0$$

for all $n$ big enough.

**Proof.** The sets $K + g$ cover $\mathbb{R}^d$ for $g \in Z(G) = \mathbb{Z}^d$, and the group $Z(G)$ is $\phi$-invariant, hence for every $x \in E_+$ and $n \geq 0$ there exists $h_n \in Z(G)$ such that $x \in \phi^n(K) + h_n$. We have then $\phi^n(K) + h_{n-1} \cap \phi^n(K) + h_n \neq \emptyset$, hence $\phi^{-1}(K) \cap K + \phi^{-n}(h_n) - \phi^{-n}(h_{n-1}) \neq \emptyset$ which implies that $\phi^{-n}(h_n) - \phi^{-n}(h_{n-1}) = g_n \in S$, i.e., $h_n = \phi^n(g_n) + h_{n-1}$. It follows that there exists a sequence $g_i \in S$ such that $h_n = \phi^n(g_n) + \phi^{n-1}(g_{n-1}) + \cdots + \phi(g_1) + g_0$.

Note that since $x \in \phi^n(K) + h_n$, we have $\|P_+(h_n) - x\| < C\lambda^n$ for some constant $C$. It follows that $x = \lim_{n \to \infty} P_+(h_n)$.

Note that the set of all limits $\lim_{n \to \infty} P_+ (\phi^n(g_n) + \phi^{n-1}(g_{n-1}) + \cdots + \phi(g_1))$ for all choices of $g_i \in S$ is a bounded subset $T_+$ of $E_+$.

Suppose that

$$\lim_{n \to \infty} P_+ (\phi^n(g_n) + \phi^{n-1}(g_{n-1}) + \cdots + \phi(g_1) + h) = \lim_{n \to \infty} P_+ (\phi^n(g'_n) + \phi^{n-1}(g'_{n-1}) + \cdots + \phi(g'_1) + h')$$

for $g_i, g'_i \in S$ and $h, h' \in Z(G)$.

Then for every $n \geq 0$ we have

$$P_+ (\phi^n(g_n) + \phi^{n-1}(g_{n-1}) + \cdots + \phi(g_1) + h) - P_+ (\phi^n(g'_n) + \phi^{n-1}(g'_{n-1}) + \cdots + \phi(g'_1) + h') = (P_+ (\phi^{n+1}(g_{n+1})) + P_+ (\phi^{n+2}(g'_{n+2})) + \cdots) - (P_+ (\phi^{n+1}(g'_{n+1})) + P_+ (\phi^{n+2}(g'_{n+2})) + \cdots) \in \phi^n(T_+ - T_+).$$

It follows that

$$P_+ (g_n + \phi^{-(n-1)}(g_{n-1}) + \cdots + \phi^{-n}(h)) - (g'_n + \phi^{-(n-1)}(g'_{n-1}) + \cdots + \phi^{-n}(h')) \in T_+ - T_+.$$

Since $\phi^{-1}$ is contracting on $E_-$, there exists a compact set $T_- \subset E_-$ such that for any $h$ and any sequence $g_i \in S$ we have

$$P_- (g_n + \phi^{-(n-1)}(g_{n-1}) + \cdots + \phi^{-n}(g_1) + \phi^{-n}(h)) \in T_-$$

for all $n$ big enough.
It follows that for all $n$ big enough the difference
\[
(g_n + \phi^{-1}(g_{n-1}) + \cdots + \phi^{-(n-1)}(g_1) + \phi^{-n}(h)) - (g_n' + \phi^{-1}(g_{n-1}') + \cdots + \phi^{-(n-1)}(g_1') + \phi^{-n}(h'))
\]
belongs to a bounded set $T = (T_+ - T_+) \oplus (T_- - T_-)$, hence we can take $N = T \cap \mathbb{Z}^d$. □

Fix a stable plaque $W_+ = W_+(x_0)$ of $\mathcal{M}$. The group $G$ acts on $W_+$ by $x \mapsto [g(x), x]$, since $G$ preserves the direct product structure of $\mathcal{M}$.

Let $v \in \mathbb{R}^d$, and denote $v_+ = P_+ (v)$ and $v_- = P_- (v)$. Using Proposition 6.6 find a sequence $g_i \in S$, $i \geq 1$, and $g_0 \in Z(G)$ such that
\[
v_+ = \lim_{n \to \infty} P_+ (\phi^n(g_n) + \cdots + \phi(g_1) + g_0),
\]
and define for $x \in W_+$
\begin{align}
(8) \quad v_+(x) &= \lim_{n \to \infty} [\phi^n(g_n) + \cdots + \phi(g_1) + g_0(x), x].
\end{align}

We also define for $x \in W_-$, where $W_-$ is an unstable plaque:
\begin{align}
(9) \quad v_-(x) &= \lim_{n \to \infty} [x, \phi^{-n}(g_n) + \cdots + \phi^{-1}(g_1) + g_0(x)],
\end{align}
where $g_i \in S$, for $i \geq 1$, and $g_0 \in Z(G)$ are such that
\[
v_- = \lim_{n \to \infty} P_- (\phi^{-n}(g_n) + \cdots + \phi^{-1}(g_1) + g_0).
\]
(Replacing in Proposition 6.6 $\phi$ by $\phi^{-1}$ and $E_+$, $P_+$ by $E_-$, $P_-$, we see that such a sequence $g_n$ exists.)

**Proposition 6.7.** The limit (8) exists and depends only on $v_+$ and $x$. The limit (9) exists and depends only on $v_-$ and $x$.

**Proof.** Follows directly from (7), Propositions 6.3 and 6.6. □

**Theorem 6.8.** The limits (8) and (9) define continuous actions of $E_+$ and $E_-$ on $W_+ = W_+(x_0)$ and $W_- = W_-(x_0)$, respectively. Their direct sum is a continuous action of $\mathbb{R}^d$ on $\mathcal{M}$. This action satisfies the following conditions:

1. it is free and proper;
2. its restriction onto $Z(G) = \mathbb{Z}^d < \mathbb{R}^d$ coincides with the original action of $Z(G)$ on $\mathcal{M}$;
3. it preserves the direct product structure, i.e., $v([x, y]) = [v(x), v(y)]$ for all $v \in \mathbb{R}^d$ and $x, y \in \mathcal{M}$;
4. $F(v(x)) = \phi(v) i (F(x))$ for all $x \in \mathcal{M}$ and $v \in \mathbb{R}^d$;
5. the action commutes with $G$, i.e., $v(g(x)) = g(v(x))$ for all $x \in \mathcal{M}$, $g \in G$, and $v \in \mathbb{R}^d$;
6. if $g(x) = v(x)$ for $g \in G$ and $v \in \mathbb{R}^d$, then $g = v \in Z(G)$.

**Proof.** The fact that (8) and (9) define actions follows directly from the fact that the limits do not depend on $S$ and the choice of the sequences $g_i$.

Let us prove that the action is continuous. It is enough to prove that the action of $E_+$ on $W_+$ is continuous. We have to show that for every $v_1 \in E_+$, $x \in W_+$, and $\epsilon > 0$ there exists $\delta > 0$ such that if $v_2 \in E_+$ and $y \in W_+$ are such that $\|v_1 - v_2\| < \delta$ and $d_+(x, y) < \delta$, then $d_+(v_1(x), v_2(y)) < \epsilon$. 

Take an arbitrary \( \epsilon > 0 \). For every \( n \) there exists \( \delta_1(n) \) and a sequence \( g_0 \in H \), \( g_i \in S \), \( i \geq 1 \), such that \( v_1 = \lim_{m \to \infty} P_+(g_0 + \phi(g_1) + \ldots + \phi^n(g_m)) \) and all points \( v_2 \) in the \( \delta_1(n) \)-neighborhood of \( v_1 \) can be represented as limits \( v_2 = \lim_{m \to \infty} P_+(h_0 + \phi(h_1) + \ldots + \phi^n(h_m)) \) for \( h_0 \in Z(G) \), and \( h_i \in S \), \( i \geq 1 \), such that \( h_i = g_i \) for \( i = 0, 1, \ldots, n \) (see the proof of Proposition 6.6 and use Lebesgue’s covering lemma). There exists \( \delta_2(n) \) such that if \( y \in W_+ \) is such that \( d_+(x, y) < \delta_2(n) \), then

\[
d_+([g_0 + \phi(g_1) + \ldots + \phi^n(g_n)](x), [g_0 + \phi(g_1) + \ldots + \phi^n(g_n)](y), y) < \epsilon/2,
\]

since the function \( y \to [(g_0 + \phi(g_1) + \ldots + \phi^n(g_n))(y), y] \) is continuous. There exist constants \( C > 0 \) and \( \lambda \in (0, 1) \) such that

\[
d_+(u(z), [(g_0 + \phi(g_1) + \ldots + \phi^n(g_n))(z), z]) < C \lambda^n
\]

for all \( z \in W_+ \) and \( u \in E_+ \) such that \( u = \lim_{m \to \infty} P_+(g_0 + \phi(g_1) + \ldots + \phi^n(g_m)) \) for \( g_0 \in Z(G) \) and \( g_i \in S \) for \( i \geq 1 \).

Take \( n \geq -\log(\log C) / \log \lambda \). Then for all \( v_2 \in E_+ \) and \( y \in W_+ \) such that \( \|v_1 - v_2\| < \delta_1(n) \) and \( d_+(x, y) < \delta_2(n) \) we have

\[
d_+(v_1(x), v_2(y)) \leq d_+(v_1(x), [(g_0 + \phi(g_1) + \ldots + \phi^n(g_n))(x), x]) +
\]

\[
d_+([g_0 + \phi(g_1) + \ldots + \phi^n(g_n)](x), [g_0 + \phi(g_1) + \ldots + \phi^n(g_n)](y), y)] +
\]

\[
d_+(v_2(y), [(g_0 + \phi(g_1) + \ldots + \phi^n(g_n))(y), y]) \leq \epsilon/4 + \epsilon/2 + \epsilon/4 = \epsilon.
\]

Which shows that the action of \( E_+ \) on \( W_+ \) is continuous.

The same arguments (using Proposition 6.3 and inequalities (7)) as in the proof of the criterion of equality of two limits in Proposition 6.6 show that an equality

\[
\lim_{n \to \infty} [\phi^n(g_n) + \cdots + \phi(g_1) + g_0](x) = \lim_{n \to \infty} [(\phi^n(g_n') + \cdots + \phi(g_1') + g_0')(x), x]
\]

for \( g_i, g_i' \in S \), \( i \geq 1 \), and \( g_0, g_0' \in Z(G) \) is equivalent to the equality

\[
\lim_{n \to \infty} P_+(\phi^n(g_n) + \cdots + \phi(g_1) + g_0) = \lim_{n \to \infty} P_+(\phi^n(g_n') + \cdots + \phi(g_1') + g_0').
\]

This (and a similar statement for \( P_- \) and the action on \( W_- \)) shows that the action of \( R^d \) is free.

Let us show that the action is proper. Let \( B \subset M \) be a compact set. We have to show that the set \( \{v \in R^d : v(B) \cap B \neq \emptyset \} \) is compact. It is closed, since the action is continuous.

Denote \( K = \{(x_i)_{i=1}^d \in R^d : |x_i| \leq 1 \} \). Then for every \( v \in R^d \) there exists \( h \in Z(G) = R^d \) such that \( v - h \in K \). The set \( K(B) = \{v(x) : x \in B, v \in K \} \) is compact, since the action is continuous and the sets \( B \) and \( K \) are compact. The action of \( G \) on \( M \) is proper, hence the set \( A \) of elements \( h \in Z(G) \) such that \( h(K(B)) \cap B \neq \emptyset \) is finite.

Suppose that \( x \in B \) and \( v \in R^d \) are such that \( v(x) \in B \). There exists \( h \in Z(G) \) such that \( v - h \in K \). Then \( v(x) = (h + v - h)(x) \in h(K(B)) \cap B \), hence \( h \in A \), so that \( v \in K + A \). But the set \( K + A \) is compact, which proves that the action of \( R^d \) on \( M \) is proper.

The proof of statements (2)–(5) is straightforward, using the fact that the action does not depend on the choice of \( S \).

Let us prove the last statement. Suppose that \( g(x) = v(x) \) for \( g \in G \) and \( v \in R^d \). Then \( g \) leaves invariant the orbit \( R^d(x) \) of \( x \). Let \( G_1 \) be the group of all elements leaving the \( R^d(x) \) invariant. The action of \( Z(G) \) on \( R^d(x) \) is co-compact,
the action of $G$ on $\mathcal{M}$ is proper, hence the index of $Z(G)$ in $G_1$ is finite, i.e., the image of $G_1$ in $G/Z(G)$ is finite. But $G/Z(G)$ is torsion free (see [Rob96, 5.2.19]). Consequently, $G_1 = Z(G)$. Since the action of $\mathbb{R}^d$ on $\mathbb{R}^d(x)$ is free, this implies that $g = v \in Z(G)$.

**Proof.** It is enough to show that for every point $x ∈ W_+$ there exists a sequence $g_i ∈ S$, $i ≥ 1$, and an element $g_0 ∈ G$ such that

$$x = \lim_{n→∞} [(\phi^n(g_n) + ⋯ + \phi(g_1) + g_0)(x_0), x_0].$$

(10)

The action of $G$ on $\mathcal{M}$ is co-compact, hence there exists a relatively compact open rectangle $R ⊂ \mathcal{M}$ containing $x_0$ and such that $\bigcup_{h ∈ G} h(R) = \mathcal{M}$.

Then for every $x ∈ W_+$ and every $n ≥ 0$ there exists $h_n ∈ G$ such that $x ∈ h_n(F^n(R))$. Assume that $S$ is big enough so that it contains all elements $h ∈ G$ such that $h(R) \cap (F(C) ∪ F^{-1}(C)) ≠ ∅$. Then the same arguments as in the proof of Proposition 6.6 show that there exists a sequence $g_i ∈ S$, $i ≥ 1$, and an element $g_0 ∈ G$ for which (6.6) holds.

**Theorem 6.10.** Let $(X, f)$ be a locally connected and connected Smale space which has a splitting with a free abelian group of deck transformations $G ≃ \mathbb{Z}^d$. Let $φ$ be the automorphism of $G$ induced by a lift of $f$. Then $(X, f)$ is topologically conjugate to the hyperbolic automorphism of the torus $\mathbb{R}^d/\mathbb{Z}^d$ induced by $φ$. In particular, $(X, f)$ has a fixed point.

**Proof.** By Proposition 6.9 the action of $\mathbb{R}^d$ on $\mathcal{M}$ defined in Theorem 6.8 is transitive.

Fix a basepoint $x_0 ∈ \mathcal{M}$, define $ρ_0 : \mathbb{R}^d → \mathcal{M}$ by $v → v(x_0)$. The map $ρ_0$ is a homeomorphism, since it is continuous, bijective, and proper. Denote $v_0 = ρ_0^{-1}(F(x_0))$, i.e., $v_0 ∈ \mathbb{R}^d$ is such that $v_0(x_0) = F(x_0)$.

Then the map $φ_0 = ρ_0^{-1}Fρ_0 : \mathbb{R}^d → \mathbb{R}^d$ satisfies

$$φ_0(v) = ρ_0^{-1}(F(v(x_0))) = ρ_0^{-1}(φ(v)(F(x_0))) = ρ_0^{-1}((φ(v) + v_0)(x_0)) = φ(v) + v_0.$$  

The linear operator $1 − φ$ is invertible, since $φ$ is hyperbolic. Therefore, there exists $w_0 ∈ \mathbb{R}^d$ such that $w_0 − φ(w_0) = v_0$, i.e., $φ_0(w_0) = φ(w_0) + v_0 = w_0$. Define then

$$ρ_1(v) = ρ_0(v + w_0).$$

We have then

$$F(ρ_1(v)) = F(ρ_0(v + w_0)) = ρ_0(φ_0(v + w_0)) = ρ_0(φ(v) + φ(w_0) + v_0) = ρ_0(φ(v) + w_0) = ρ_1(φ(v)).$$

The statement of the theorem follows now directly from Theorem 6.8.

Let us go back to the case when $G$ is torsion free nilpotent.

**Proposition 6.11.** The action of $\mathbb{R}^d$ on $\mathcal{M}$ is uniformly locally Lipschitz, i.e., there exist $ε > 0$ and $C > 1$ such that for every $v ∈ \mathbb{R}^d$ and all $x, y ∈ \mathcal{M}$ such that $d_\mathcal{M}(x, y) < ε$ we have

$$d_\mathcal{M}(v(x), v(y)) ≤ Cd_\mathcal{M}(x, y).$$

Note that it follows that $C^{-1}d_\mathcal{M}(x, y) ≤ d_\mathcal{M}(v(x), v(y))$ for all $x, y ∈ \mathcal{M}$ such that $d_\mathcal{M}(x, y) ≤ C^{-1}ε.$
Proof. By Theorem 6.8, $G$ maps $\mathbb{R}^d$-orbits to $\mathbb{R}^d$-orbits.

Let $K = \{(x, y) \in \mathbb{R}^d : \|x\| \leq 1\}$, and let $R \subset M$ be a relatively compact rectangle such that $\pi(R) = X$. Let $\epsilon > 0$ and $C > 1$ be such that

\[
C^{-1}d_M(x, y) \leq d_+(x, [y, x]) + d_-(x, [x, y]) \leq Cd_M(x, y)
\]

for all $x, y \in M$ such that $d_M(x, y) < \epsilon$, see Subsection 5.2, where the metric $d_M$ is defined. We also assume that $\epsilon$ is sufficiently small so that for all $x, y \in M$ such that $d_M(x, y) < \epsilon$ there exists $g \in G$ such that $g(x), g(y) \in R$.

Let $\delta$ be such that $d_M(v(x), v(y)) < \epsilon$ for all $v \in K$ and all $x, y \in R$ such that $d_M(x, y) < \delta$. It exists, since the action of $\mathbb{R}^d$ is continuous, and the set $K$ and the closure of $R$ are compact. For all $x, y \in M$ such that $d_M(x, y) < \delta$ and all $v \in \mathbb{R}^d$ there exists $g \in G$ and $h \in Z(G)$ such that $g(x), g(y) \in R$, and $v + h \in K$. Then $d_M(g(x), g(y)) < \delta$, hence

\[
d_M(v(x), v(y)) = d_M(g^{-1} \cdot v \cdot g(x), g^{-1} \cdot v \cdot g(y)) = d_M((h + v)(g(x)), (h + v)(g(y))) < \epsilon.
\]

We have shown that for all $x, y \in M$ such that $d_M(x, y) < \delta$ and all $v \in \mathbb{R}^d$ we have $d_M(v(x), v(y)) < \epsilon$.

Let $x, y \in M$ be such that $d_M(x, y) < \epsilon$. Let $n$ be biggest positive integer such that $d_+(F^{-n}(x), F^{-n}([y, x])) < C^{-1}\delta$. Then $n$ is equal, up to an additive constant, to $- \log d_+(x, [y, x])/\alpha_+$, where $\alpha_+$ is the exponent of $d_+$.

We have then $d_+(v(F^{-n}(x)), v(F^{-n}([y, x]))) < \epsilon$ for all $v \in \mathbb{R}^d$. Applying $F^n$, and using the fact that $\phi$ is an automorphism of $\mathbb{R}^d$, we get that $d_+(u(x), u([y, x])) \leq C_1 e^{-n\alpha_+} \leq C_2 d_+(x, [y, x])$ for all $u \in \mathbb{R}^d$, where $C_1, C_2$ are constant (not depending on $x, y$).

In the same way we prove that $d_-(u(x), u([x, y])) < C_3 d_-(x, [x, y])$ for all $u \in \mathbb{R}^d$, if $d_M(x, y) < \epsilon$. It follows then from (11) that there exist $\epsilon_1 > 0$ and $C_4 > 0$ such that if $x, y \in M$ are such that $d_M(x, y) < \epsilon_1$, then $d_M(u(x), u(y)) < C_4 d_M(x, y)$ for all $u \in \mathbb{R}^d$.

Let $\overline{M}$ be the quotient of $M$ by the $\mathbb{R}^d$-action defined in Theorem 6.8. We denote for $x \in M$ by $\overline{x}$ the $\mathbb{R}^d$-orbit of $x$. Since $G$ maps $\mathbb{R}^d$-orbits to $\mathbb{R}^d$-orbits, the action of $G$ on $M$ induces a well-defined action of $G$ on $\overline{M}$. Denote $\overline{G} = G/Z(G)$, it is a torsion-free finitely generated nilpotent group of nilpotency class one less than the class of $G$. By Theorem 6.8 $Z(G)$ is equal to the kernel of the action of $G$ on $\overline{M}$, and the action of $\overline{G}$ on $\overline{M}$ is free.

The action of $\mathbb{R}^d$ on $M$ descends to a free action of $\mathbb{R}^d/Z^d$ on $X$, whose orbits are the images of the $\mathbb{R}^d$-orbits under the map $\pi : M \to X$. Let $\overline{\pi} : \overline{M} \to \overline{X}$ be the corresponding map induced by $\pi : M \to X$.

Denote, for $\overline{x}, \overline{y} \in \overline{M}$

\[
\delta(\overline{x}, \overline{y}) = \inf\{x_1 \in \overline{x}, y_1 \in \overline{y} : d_M(x_1, y_1)\}.
\]

Lemma 6.12. There exist $\epsilon > 0, C > 1$ and a $\overline{G}$-invariant metric $\overline{d}$ on $\overline{M}$ such that

\[
C^{-1}\delta(\overline{x}, \overline{y}) \leq \overline{d}(\overline{x}, \overline{y}) \leq C\delta(\overline{x}, \overline{y})
\]

for all $x, y$ such that $\delta(x, y) < \epsilon$.

Proof. The function $\delta$ is $\overline{G}$-invariant, since the metric $d_M$ is $G$-invariant. Note that $\delta(x, y) > 0$ for all $x \neq y$, since the quotient map $\pi : (M, d_M) \to (X, d)$ is a local
isometry, the images of $\mathcal{X}$ and $\overline{\mathcal{X}}$ in $\mathcal{X}$ are compact, hence distance between any two points of $\pi(\mathcal{X})$ and $\pi(\overline{\mathcal{X}})$ are bounded from below.

Let $\varepsilon$ be as in Proposition 6.11. Define $\delta(\mathcal{X}, \overline{\mathcal{X}})$ as infimum of $\sum \delta(\mathcal{X}_i, \mathcal{X}_{i+1})$ over all sequences $\mathcal{X} = \mathcal{X}_0, \ldots, \mathcal{X}_n = \overline{\mathcal{X}}$ such that $\delta(\mathcal{X}_i, \mathcal{X}_{i+1}) < \varepsilon$. Note that by Proposition 6.11 there exists $C > 1$ such that $\delta(\mathcal{X}, \overline{\mathcal{X}}) \leq C \sum \delta(\mathcal{X}_i, \mathcal{X}_{i+1})$, hence

$$\delta(\mathcal{X}, \overline{\mathcal{X}}) \leq C \delta(\mathcal{X}, \overline{\mathcal{X}})$$

for all $\mathcal{X}, \overline{\mathcal{X}} \in \mathcal{M}$. We also have

$$\overline{\delta}(\mathcal{X}, \overline{\mathcal{X}}) \leq \delta(\mathcal{X}, \overline{\mathcal{X}})$$

for all $\mathcal{X}, \overline{\mathcal{X}}$ such that $\delta(\mathcal{X}, \overline{\mathcal{X}}) < \varepsilon$. □

**Proposition 6.13.** The topology defined by the metric $\overline{d}$ coincides with the quotient topology on $\mathcal{M}$. The map $\overline{\pi} : \mathcal{M} \longrightarrow \mathcal{X}$ is uniformly locally bi-Lipschitz with respect to $\overline{d}$ and the metric on $\mathcal{X}$ coming from the Hausdorff distance between compact subsets of $\mathcal{X}$.

**Proof.** By Proposition 6.11 and definition of $\overline{d}$, there exist $C > 1$ and $\varepsilon > 0$ such that if $\overline{d}(\mathcal{X}, \overline{\mathcal{X}}) < \varepsilon$, then for every $y \in \overline{\mathcal{X}}$ there exists $x \in \mathcal{X}$ such that $d_\mathcal{M}(x, y) < C\varepsilon$. Suppose that $\mathcal{U} \subset \mathcal{M}$ is open with respect to $\overline{d}$. Let $U \subset \mathcal{M}$ be the preimage of $\mathcal{U}$. Then for every $\mathcal{X} \in U$ there exists $\varepsilon > 0$ such that the $\epsilon$-neighborhood of $\mathcal{X}$ (with respect to $\overline{d}$) is contained in $U$. Let $\overline{\mathcal{X}}$ be such that $\overline{d}(\mathcal{X}, \overline{\mathcal{X}}) < C^{-1}\varepsilon$. Then for every $y \in \overline{\mathcal{X}}$ there exists $x \in \mathcal{X}$ such that $d_\mathcal{M}(x, y) < \varepsilon$. It follows that the $\epsilon$-neighborhood of the set $\mathcal{X}$ contains the set $\overline{\mathcal{X}}$. It follows that $U$ is open in $\mathcal{M}$.

Suppose that $U \subset \mathcal{M}$ is an $\mathbb{R}^d$-invariant open subset of $\mathcal{M}$. Then for every $x \in U$ there exists $\varepsilon > 0$ such that the $\epsilon$-neighborhood of $x$ is contained in $U$. Suppose that $\overline{\mathcal{X}} \subset U$ is such that $\overline{d}(\mathcal{X}, \overline{\mathcal{X}}) < C^{-1}\varepsilon/2$. Then there exists $y \in \overline{\mathcal{X}}$ such that $d_\mathcal{M}(x, y) \leq \varepsilon$. Then $y \in U$, hence $\overline{\mathcal{X}} \subset U$, since $U$ is $\mathbb{R}^d$-invariant. We have shown that every set that is open in the quotient topology is also open with respect to $\overline{d}$.

The statement about the Hausdorff distance also follows directly from the definition of $\overline{d}$ and Proposition 6.11 (and the fact that $\pi : \mathcal{M} \longrightarrow \mathcal{X}$ is a local isometry). □

Note that $v(x) = [v_+(x), v_-(x)]$, where $v_+ = P_+(v)$ and $v_- = P_-(v)$. It follows that for any $v, u \in \mathbb{R}^d$ and $x, y \in \mathcal{M}$ we have

$$[v(x), u(y)] = [v_+(x), u_-(y)] = [(v_+ + u_-)(x), (v_+ + u_-)(y)] = (v_+ + u_-)(x, y),$$

i.e., the value of $[x, y]$ depends only on $\mathcal{X}$ and $\overline{\mathcal{X}}$. It follows that the function $[\mathcal{X}, \overline{\mathcal{X}}] = [x, y]$ is well defined and satisfies the equalities (1) and (2) of Definition 2.1. We will prove that it is continuous in the next proposition.

We also have a well defined homeomorphism $\overline{F}(\mathcal{X}) = \overline{F}(x)$, by condition (4) of Theorem 6.8.

**Lemma 6.14.** The metric $\overline{d}$ agrees with the local product structure on $\mathcal{M}$. In particular, the map $[\cdot, \cdot]$ is continuous.

**Proof.** We know that the metric $d_\mathcal{M}$ on $\mathcal{M}$ agrees with the local product structure on $\mathcal{M}$, since it is locally isometric to the standard metric on $\mathcal{X}$. Let $\mathcal{X}, \overline{\mathcal{X}}$ be points of $\mathcal{M}$ such that $\delta(\mathcal{X}, \overline{\mathcal{X}})$ is small. Let us prove that

$$\delta(\mathcal{X}, \overline{\mathcal{X}}) \approx \delta(\mathcal{X}, [\mathcal{X}, \overline{\mathcal{X}}]) + \delta([\mathcal{X}, \overline{\mathcal{X}}], [\mathcal{X}, \overline{\mathcal{X}}])$$
for all $\mathbf{x}$ and $\mathbf{y}$ that are close enough to each other. (Here $F_1 \simeq F_2$ means that there exists a constant $C > 1$ such that $C^{-1}F_1 \leq F_2 \leq CF_1.$)

There exist points $x \in \mathbf{x}$ and $y \in \mathbf{y}$ such that $d_M(x, y) \leq 2\delta(\mathbf{x}, \mathbf{y})$. Since $d$ agrees with the local product structure on $M$, we have

$$d_M(x, y) \simeq d_M(x, [x, y]) + d_M([x, y], y).$$

We have $\delta(x, [x, y]) \leq d_M(x, [x, y])$ and $\delta(y, [x, y]) \leq d_M(y, [x, y])$, hence there exists a constant $C_1 > 1$ such that

$$\delta(x, y) \geq C_1^{-1}(\delta(x, [x, y]) + \delta(y, [x, y])).$$

On the other hand, since $\delta$ is equivalent to a metric (see Lemma 6.12), there exists $C_2 > 1$ such that

$$\delta(x, y) \leq C_2(\delta(x, [x, y]) + \delta(y, [x, y])).$$

by the triangle inequality. This proves (12).

**Lemma 6.15.** There exists $C > 1$ and $\epsilon > 0$ such that if $\mathbf{x}, \mathbf{y} \in \overline{M}$ are such that $[\mathbf{x}, \mathbf{y}] = \mathbf{x}$ (i.e., $\mathbf{x}$ and $\mathbf{y}$ belong to the same stable plaque of $M$) and $\delta(\mathbf{x}, \mathbf{y}) < \epsilon$, then there exist $x \in \mathbf{x}$ and $y \in \mathbf{y}$ such that $[x, y] = x$ and $d_M(x, y) \leq C\delta(\mathbf{x}, \mathbf{y})$.

**Proof.** Let $x, y$ belong to one stable plaque of $M$. There exist $\epsilon > 0$ and $C > 1$ (not depending on $x, y$) such that if $d_M([x, g(x)], [y, h(y)]) < \epsilon$ for $g, h \in G$, then

$$d_M([x, g(x)], [y, h(y)]) \geq C^{-1}(d_M([x, g(x)], [y, g(y)]) + d_M([y, g(y)], [y, h(y)])) \geq C^{-1}d_M([x, g(x)], [y, g(y)]),$$

see Figure 3.

It follows that

$$(13) \quad \inf\{d_M(v(x), u(y)) : v, u \in E_+\} \geq C^{-1}\inf\{d_M(v(x), v(y)) : v \in E_+\},$$

if the left hand side of the inequality is less than $\epsilon$.

We always can find $x_1 \in \mathbf{x}$ and $y_1 \in \mathbf{y}$ such that $d_M(x_1, y_1) \leq 2\delta(\mathbf{x}, \mathbf{y})$. Then $[x_1, y_1] = v(x_1)$ for some $v \in \mathbb{R}^d$. 
Note that \([x_1, y_1]\) and \(x_1\) belong to the same unstable plaque of \(\mathcal{M}\), hence \(v \in E_-\). Then \([v(x_1), y_1] = [x_1, y_1] = v(x_1)\), i.e., the points \(v(x_1)\) and \(y_1\) belong to the same stable plaque.

It follows from (13) that

\[
\inf\{d_\mathcal{M}(uv(x_1), u(y_1)) : u \in E_-\} \leq C \inf\{d_\mathcal{M}(uv(x_1), w(y_1)) : u, w \in E_-\} \leq C d_\mathcal{M}(x_1, y_1) \leq 2C \delta(\mathcal{X}, \mathcal{Y}).
\]

It follows that there exists a pair of points \(x' \in \mathcal{X}, y' \in \mathcal{Y}\) such that \(x'\) and \(y'\) belong to the same stable plaque, and \(d_\mathcal{M}(x', y') \leq 2C \delta(\mathcal{X}, \mathcal{Y})\).

Let \(\mathcal{X}, \mathcal{Y} \in \mathcal{M}\) be such that \(\delta(\mathcal{X}, \mathcal{Y})\) is small, and \([\mathcal{X}, \mathcal{Y}] = \mathcal{X}\). Let \(\mathcal{X}_2 \in \mathcal{M}\) be a point close to \(\mathcal{X}\). Using Lemma 6.15, find \(x \in \mathcal{X}\) and \(y \in \mathcal{Y}\) such that \([x, y] = x\) and \(d_\mathcal{M}(x, y) \leq C_1 \delta(\mathcal{X}, \mathcal{Y})\). By Proposition 6.11, there exists \(x_2 \in \mathcal{X}_2\) such that \(d_\mathcal{M}(x, x_2) \leq C_2 \delta(\mathcal{X}, \mathcal{X}_2)\). We conclude from this, and from the fact that \(d_\mathcal{M}\) agrees with the local product structure on \(\mathcal{M}\), that there exists a constant \(C_3 > 1\) such that if \(d_\mathcal{M}(x, y)\) and \(\delta(\mathcal{X}, \mathcal{X}_2)\) are small enough, we have

\[
d_\mathcal{M}([x, x_2], [y, x_2]) \leq C_3 d_\mathcal{M}(x, y).
\]

Consequently,

\[
\delta([\mathcal{X}, \mathcal{X}_2], [\mathcal{Y}, \mathcal{X}_2]) \leq d_\mathcal{M}([x, x_2], [y, x_2]) \leq C_3 d_\mathcal{M}(x, y) \leq C_3 C \delta(\mathcal{X}, \mathcal{Y}).
\]

It follows that the maps \(W_+(\mathcal{X}_1) \rightarrow W_+(\mathcal{X}_2) : \mathcal{X} \mapsto [\mathcal{X}, \mathcal{X}_2]\) are locally Lipschitz with respect to the metric \(\bar{d}\). Since inverses of these maps are also maps of the same form, they are in fact locally bi-Lipschitz. This shows that the local product structure on \(\mathcal{M}\) agrees with \(\bar{\mathcal{M}}\).

**Proposition 6.16.** The dynamical system \((\mathcal{X}, \bar{\mathcal{Y}})\), where \(\bar{\mathcal{Y}}\) is the map induced by \(\mathcal{Y}\) is a connected and locally connected Smale space. The quotient map \(\mathcal{M} \rightarrow \mathcal{X}\) is a splitting with the group of deck transformations \(\mathcal{G}\).

**Proof.** It follows from Theorem 6.8 that \(\bar{\mathcal{Y}} : \mathcal{X} \rightarrow \mathcal{X}\) is a well defined homeomorphism. The plaques of the direct product structure of \(\mathcal{M}\) are continuous images of plaques of \(\mathcal{M}\), hence they are connected. The map \(\mathcal{F}\) is a lift of \(\mathcal{Y}\).

The map \(\mathcal{F} : \mathcal{M} \rightarrow \mathcal{X}\) is uniformly locally bi-Lipschitz with respect to \(\bar{d}\) and the Hausdorff distance on \(\mathcal{X}\), by Proposition 6.13. It follows that the Hausdorff distance agrees with the quotient topology on \(\mathcal{X}\) and that \(\mathcal{F}\) is a covering.

It follows from Proposition 6.13, Lemma 6.14, and the fact that \(\mathcal{G}\) preserves the direct product structure on \(\mathcal{M}\), that the image under \(\mathcal{F}\) of the local product structure on \(\mathcal{M}\) is a well defined local product structure on \(\mathcal{X}\).

Suppose that \(\mathcal{X}, \mathcal{Y} \in \mathcal{M}\) are such that \([\mathcal{X}, \mathcal{Y}] = \mathcal{X}\) (i.e., \(\mathcal{X}\) and \(\mathcal{Y}\) belong to the same stable plaque of \(\mathcal{M}\)). By Lemma 6.15, there exist \(x \in \mathcal{X}\) and \(y \in \mathcal{Y}\) belonging to the same stable plaque of \(\mathcal{M}\). Note also that it follows from Lemmas 6.12 and 6.14 that there exists a constant \(C > 1\), not depending on \(\mathcal{X}\) and \(\mathcal{Y}\), such that we can find \(x, y\) satisfying

\[
C^{-1} \bar{d}(\mathcal{X}, \mathcal{Y}) \leq d_\mathcal{M}(x, y) \leq C \bar{d}(\mathcal{X}, \mathcal{Y}),
\]

provided that \(\bar{d}(\mathcal{X}, \mathcal{Y})\) is small enough.

Then \(d_\mathcal{M}(F^\lambda(x), F^\lambda(y)) \leq C \lambda d_\mathcal{M}(x, y)\) for some fixed \(C > 1\) and \(\lambda \in (0, 1)\). It follows that there exists a constant \(C_2 > 1\) such that for any two points \(\mathcal{X}, \mathcal{Y} \in \mathcal{M}\) such that \([\mathcal{X}, \mathcal{Y}] = \mathcal{X}\), and \(\bar{d}(\mathcal{X}, \mathcal{Y})\) is small enough we have \(\bar{d}(F^\lambda(\mathcal{X}), F^\lambda(\mathcal{Y})) \leq C \lambda \bar{d}(\mathcal{X}, \mathcal{Y})\).
$C_n \lambda^n d(x, y)$ for all $n$. Analogous statement about the unstable plaques of $\overline{M}$ is proved in the same way.

The map $\overline{\pi} : \overline{M} \to \overline{\mathcal{X}}$ is locally bi-Lipschitz with respect to $d$ and the Hausdorff distance on $\overline{\mathcal{X}}$. It follows that the images of the stable and unstable plaques of $\overline{M}$ are stable and unstable leaves of $(\overline{\mathcal{X}}, F)$. Suppose that $\overline{x}, \overline{y} \in \overline{M}$ are such that $\overline{\pi}(\overline{x}) = \overline{\pi}(\overline{y})$, i.e., the $\mathbb{R}^d$-orbits $\overline{x}$ and $\overline{y}$ are mapped to the same set in $\overline{\mathcal{X}}$. Then there exist $x, y \in \mathcal{X}$ such that $\pi(x) = \pi(y)$, i.e., there exists $g \in G$ such that $g(x) = y$. Then $\overline{\pi}(\overline{x}) = \overline{\pi}(\overline{y})$. Since the action of $G$ on $\overline{M}$ is free, we conclude that $G$ is the group of deck transformations of the splitting $\overline{\pi} : \overline{M} \to \overline{\mathcal{X}}$. □

Proposition 6.17. If a connected and locally connected Smale space $(\mathcal{X}, f)$ has a splitting with a nilpotent torsion free group of deck transformations, then $f$ has a fixed point.

Proof. We argue by induction on the nilpotency class. We know that the statement is true for abelian groups of deck transformations, see Theorem 6.10. The Smale space $(\overline{\mathcal{X}}, \overline{F})$ is a locally connected Smale space with the group of deck transformations $\overline{G}$ of lower class. Therefore, by the inductive hypothesis, $\overline{F}$ has a fixed point. Its preimage in $\overline{\mathcal{X}}$ is an $f$-invariant torus $T \subset \mathcal{X}$ equal to an orbit of the $\mathbb{R}^d/\mathbb{Z}^d$-action. It follows from the definition of the action of $\mathbb{R}^d$ on $\mathcal{M}$ that $T$ is locally closed with respect to the local product operation $[\cdot, \cdot]$, hence $(T, f)$ is a Smale space, and $f$ restricted to this torus is a hyperbolic automorphism, hence it has a fixed point (see Theorem 6.10). □

If $G$ is a torsion-free finitely generated nilpotent group, then there exists a unique simply connected nilpotent Lie group $L$ such that $G$ is isomorphic to a co-compact lattice in $L$, see [Mal49]. Moreover, every automorphism of $G$ is uniquely extended to $L$. The Lie group $L$ is called the Malcev completion of $G$.

Let $G$ be a finitely generated torsion free nilpotent group, and let $\phi$ be its automorphism. We say that $\phi: G \to G$ is hyperbolic if its unique extension $\phi: L \to L$ to the Malcev completion is hyperbolic, i.e., if the automorphism $D\phi$ of the Lie algebra of $L$ has no eigenvalues on the unit circle.

Proposition 6.18. Let $(\mathcal{X}, f)$ be a connected and locally connected Smale space with a splitting $\pi : \mathcal{M} \to \mathcal{X}$ with a torsion free nilpotent group of deck transformations $G$. Let $\phi$ be an automorphism of $G$ induced by a lift $F$ of $f$ which has a fixed point in $\mathcal{M}$. Then $\phi$ is hyperbolic.

Proof. Let us prove our proposition by induction on the nilpotency class of $G$. It is true for abelian groups, by Proposition 6.5.

Suppose that we have proved the proposition for all nilpotent groups of class $n$. Suppose that nilpotency class of $G$ is $n + 1$. By Proposition 6.10 and the inductive hypothesis, the automorphism of $\overline{G}$ induced by $\phi$ is hyperbolic.

Let $x_0 \in \mathcal{M}$ be the fixed point of $F$. Then $\overline{x_0} \in \overline{M}$ is a fixed point of $\overline{F}$. Image of $\overline{x_0}$ in $\overline{\mathcal{X}}$ is an $f$-invariant torus $T$, such that $(T, f)$ is topologically conjugate to a hyperbolic automorphism of the torus.

The map $\pi : \overline{x_0} \to T$ is its splitting with the group of deck transformations equal to $Z(G) = \mathbb{Z}^d$. It follows then from Proposition 6.5 that the restriction of $\phi$ onto $Z(G)$ is hyperbolic.
Let us show that there exists a $G$-equivariant map $h : \mathcal{M} \to L$ such that $\phi \circ h = h \circ F$ and $h(x_0) = 1$.

Proof. Let us show now that there exists a $G$-equivariant map $h : \mathcal{M} \to L$ such that $\phi \circ h = h \circ F$. We will use the arguments of [Fra70] Theorem 2.2], which we repeat here for sake of completeness, and since our setting is slightly different.

Consider the space $Q$ of all continuous maps $\gamma : \mathcal{X} \to L$ such that $\gamma(\pi(x_0)) = 1$ with topology of uniform convergence on $\mathcal{X}$. It is a nilpotent group (of the same class as $L$) with respect to pointwise multiplication. Define $\Phi_0(\gamma) = \phi^{-1} \circ \gamma \circ f$. Then $\Phi_0$ is a continuous automorphism of the group $Q$.

Let $\mathfrak{L}$ be the Lie algebra of $L$, and let $\exp : \mathfrak{L} \to L$ be the exponential map. It is a diffeomorphism, since $L$ is simply connected and nilpotent. Let $\mathfrak{Q}$ be the Banach space of continuous maps $\mathcal{X} \to \mathfrak{L}$ mapping $\pi(x_0)$ to zero. Then $\Log : \gamma \mapsto \exp^{-1} \circ \gamma$ is a homeomorphism of $Q$ with $\mathfrak{Q}$.

Let $T_0 : Q \to Q$ be defined by $T_0(\gamma) = \Phi_0(\gamma)\gamma^{-1}$. Let us show that $T_0$ is a homeomorphism. We show that it is a local homeomorphism at the identity (i.e., the constant map $x \mapsto 1$), using the homeomorphism $\Log : Q \to \mathfrak{Q}$ and computing the derivative of $T = \Log \circ T_0 \circ \Log^{-1}$. Denote $\Phi = \Log \circ \Phi_0 \circ \Log^{-1}$.

We have $\exp \circ d\phi = \phi \circ \exp$, where $d\phi$ is the derivative of $\phi : L \to L$ at the identity. It follows that $d\phi^{-1} \circ \exp^{-1} = \exp^{-1} \circ \phi^{-1}$, and for every $\gamma \in \mathfrak{Q}$ we have

$$
\Phi(\gamma) = \Log \circ \Phi_0 \circ \Log^{-1}(\gamma) = \exp^{-1} \circ \phi^{-1} \circ \exp \circ \gamma \circ f = d\phi^{-1} \circ \exp^{-1} \circ \exp \circ \gamma \circ f = d\phi^{-1} \circ \gamma \circ f.
$$

It follows that $\Phi : \mathfrak{Q} \to \mathfrak{Q}$ is linear.
For every $\gamma \in \Omega$, we have
\[
T(\gamma) = \Log \circ T_0 \circ \Log^{-1}(\gamma) = \\
\exp^{-1}(T_0(\exp \circ \gamma)) = \exp^{-1}(\Phi_0(\exp \circ \gamma) \cdot (\exp \circ \gamma)^{-1}) = \\
\exp^{-1}(\exp \circ \Phi(\gamma) \cdot (\exp \circ \gamma)^{-1}) = \\
\Log(\Log^{-1}(\Phi(\gamma)) \cdot \Log^{-1}(\gamma)^{-1}) = \Log(\Log^{-1}(\Phi(\gamma)) \cdot \Log^{-1}(-\gamma)),
\]
since $(\Log^{-1}(\gamma))^{-1} = (\exp(\gamma))^{-1} = \exp(-\gamma(x))$ for all $x \in X$.

Let us compute the derivative of $T$ at zero. If $\gamma \in \Omega$, then
\[
\lim_{t \to 0} \frac{1}{t} T(t\gamma) = \lim_{t \to 0} \frac{1}{t} \Log(\Log^{-1}(\Phi(t\gamma))) \Log^{-1}(-t\gamma) = \Phi(\gamma) - \gamma,
\]
by the Campbell-Hausdorff formula.

Since $d\phi$ is hyperbolic, there exist a direct sum decomposition $L = L_+ \oplus L_-$ and constants $C > 0$ and $0 < \lambda < 1$ such that $\|d\phi^n(v)\| \leq C\lambda^n \|v\|$ for all $n \geq 0$ and $v \in L_+$, and $\|d\phi^{-n}(v)\| \leq C\lambda^n \|v\|$ for all $n \geq 0$ and $v \in L_-$. Define
\[
\Omega_+ = \{ \gamma \in \Omega : \gamma(X) \subset L_+ \},
\]
for $* \in \{+, -\}$. Since $L_+$ and $L_-$ are $d\phi$-invariant, the spaces $\Omega_+$ and $\Omega_-$ are $\Phi$-invariant. We obviously have $\Omega = \Omega_+ \oplus \Omega_-$, $\|\Phi^n(\gamma)\| \leq C\lambda^n \|\gamma\|$ for $n \geq 0$, $\gamma \in \Omega_+$, and $\|\Phi^{-n}(\gamma)\| \leq C\lambda^n \|\gamma\|$ for $n \geq 0$, $\gamma \in \Omega_-$. It follows that $\Phi - I$ is invertible.

This shows that $T$ is a local homeomorphism at zero. Consequently, $T_0$ is a local homeomorphism at the identity of $Q$. Let us show that $T_0$ is surjective. Let $Z_1(Q) = Z(Q) \subset Z_2(Q) \subset \cdots \subset Z_n(Q) = Q$ be the upper central series of $Q$. Let us prove by induction on $i$ that $T_0(Q) \supseteq Z_i(Q)$. It is easy to see that $T_0(\gamma_1 \gamma_2) = T_0(\gamma_1)T_0(\gamma_2)$ for all $\gamma_1, \gamma_2 \in Z(Q)$. Since $T_0$ is a local homeomorphism at the identity and $Z(Q)$ is generated by any neighborhood of the identity (as any connected topological group, see [Pon66, Theorem 15, p. 76], this implies that $Z(Q) \subset T_0(Q)$.

Suppose that we have proved that $Z_i(Q) \subset T_0(Q)$. Let $T_0(\gamma_1), T_0(\gamma_2) \in Z_{i+1}(Q)$. Then
\[
T_0(\gamma_1)T_0(\gamma_2) = \Phi_0(\gamma_1)\gamma_1^{-1}\Phi_0(\gamma_2)\gamma_2^{-1} = \\
\Phi_0(\gamma_1)\Phi_0(\gamma_2) \cdot (\Phi_0(\gamma_2)^{-1}\gamma_1^{-1}\Phi_0(\gamma_2)^{-1}\gamma_2^{-1} \gamma_1 \gamma_2) \cdot \gamma_2^{-1}\gamma_1^{-1}.
\]
We have
\[
\gamma' = \Phi_0(\gamma_2)^{-1}\gamma_1^{-1}\Phi_0(\gamma_2)\gamma_2^{-1} \gamma_1 \gamma_2 = \gamma_2^{-1}(\Phi_0(\gamma_2)\gamma_2^{-1})^{-1}\gamma_1^{-1}(\Phi_0(\gamma_2)\gamma_2^{-1})\gamma_1 \gamma_2 = \\
\gamma_2^{-1}T_0(\gamma_2)^{-1}\gamma_1^{-1}T_0(\gamma_2)T_0(\gamma_2)T_0(\gamma_2) = \gamma_2^{-1}[T_0(\gamma_2), \gamma_1] \subset Z_i(Q)
\]
(here $[T_0(\gamma_2), \gamma_1]$ is the commutator, and has nothing to do with the direct product decomposition). By the inductive hypothesis, there exists $\gamma_3 \in Q$ such that $\gamma' = T_0(\gamma_3)$. Then
\[
T_0(\gamma_1)T_0(\gamma_2) = \Phi_0(\gamma_1)\Phi_0(\gamma_2)\Phi_0(\gamma_3)\gamma_3^{-1}\gamma_2^{-1}\gamma_1^{-1} = T_0(\gamma_1\gamma_2\gamma_3) \in T_0(Q).
\]
Since $Z_{i+1}(Q)$ is connected, hence generated by any neighborhood of the identity, it follows that $Z_{i+1}(Q) \subset T(Q)$.

Since $\Phi - I$ is invertible, the only fixed point of $\Phi$ is 0. Consequently, the only fixed point of $\Phi_0$ is the unit of $Q$. If $T(\gamma_1) = T(\gamma_2)$, then $\Phi_0(\gamma_1)^{-1} = \Phi_0(\gamma_2)^{-1}$,
hence $\Phi_0(\gamma_2^{-1}\gamma_1) = \gamma_2^{-1}\gamma_1$. But then $\gamma_1 = \gamma_2$, as the identity is the only fixed point of $\Phi_0$.

We have proved that $T_0 : Q \to Q$ is a homeomorphism. Let $h_0 : M \to L$ be any $G$-equivariant map. Consider the map

$$\tau(x) \mapsto (\phi^{-1} \circ h_0 \circ F(x))^{-1} \cdot h_0(x).$$

It is easy to see that for every $g \in G$ we have

$$\tau(g(x)) = \tau(x),$$

i.e., $\tau$ is constant on $G$-orbits, hence it descends to a continuous map $\gamma : \mathcal{X} \to L$, which is an element of $Q$. There exists $\gamma' \in Q$ such that $T(\gamma') = \gamma$. Then

$$F_0(\gamma')(\gamma')^{-1} = \gamma,$$

which means that $\gamma'(f(x)) = \phi(\gamma(x)) \cdot \phi(\gamma'(x))$.

Then the map $h(x) = h_0(x) \cdot \gamma'(\pi(x))$ is $G$-equivariant, and

$$h(F(x)) = h_0(F(x)) \cdot \gamma'(f(\pi(x))) =$$

$$h_0(F(x)) \cdot \phi(\tau(x)) \cdot \phi(\gamma'(\pi(x))) =$$

$$h_0(F(x))h_0(F(x))^{-1} \phi(h_0(x)) \phi(\gamma'(\pi(x))) =$$

$$\phi(h_0(x)\gamma'(\pi(x))) = \phi(h(x)),$$

which finishes the proof of the proposition. \hfill \Box

Theorem \textbf{6.11} shows now that $(\mathcal{X}, f)$ and $(G \backslash L, f_L)$ are topologically conjugate. \hfill \Box

Let us finish the proof of Theorem \textbf{6.1} Let $(\mathcal{X}, f)$ be a connected and locally connected Smale space, and let $\pi : M \to \mathcal{X}$ be its splitting with a virtually nilpotent group of deck transformations $G$. Let $F$ be a lift of $f$ to $M$. Let $\phi$ be the automorphism induced by $F$ on $G$.

Every finitely generated virtually nilpotent group $G$ contains a torsion free nilpotent subgroup $G_0$ of finite index (see [KM79, 17.2.2]). For every $g \in G$ and $n \in \mathbb{Z}$ the subgroup $g^{-1}\phi^n(G_0)g$ has the same index in $G$ as $G_0$. There exists only a finite number of subgroups of given index in a finitely generated group. Taking then intersection of all subgroups of the form $g^{-1}\phi^n(G_0)g$ for $n \in \mathbb{Z}$ and $g \in G$, we get a normal $\phi$-invariant torsion free nilpotent subgroup $G_1$ of finite index in $G$. It will be finitely generated as a finite index subgroup of a finitely generated group.

Then $G_1 \backslash M$ together with the map $f_1$ induced by $F$ is a Smale space. It is a finite covering of $\mathcal{X}$, and its group of deck transformations is $G_1$. Then, by Proposition \textbf{6.17}, $f_1$ has a fixed point, hence we may assume that $F$ has a fixed point $x_0$. We assume then that $\phi : G \to G$ is given by $\phi(g)(x_0) = F(g(x_0))$.

Let $L$ be the Malcev completion of $G_1$. Extend $\phi : G_1 \to G_1$ to an automorphism $\phi : L \to L$. Then, by Theorem \textbf{6.19} there exists a homeomorphism $\Phi : L \to M$ conjugating the actions of $G_1$ on $M$ and $L$, and such that $\Phi \circ F = \phi \circ L$. Note that $\Phi(1) = x_0$, $\Phi(L_+) = W_+$, and $\Phi(L_-) = W_-$, where $L_+ = W_+(1)$, $L_- = W_-(1)$ are the stable and unstable plaques of the identity element of $L$, and $W_+ = W_+(x_0), W_- = W_-(x_0)$ are the stable and unstable plaques of $x_0$.

Note that $L_+ = \{g \in L : \lim_{n \to +\infty} \phi^n(g) = 1 \}$ and $L_- = \{g \in L : \lim_{n \to -\infty} \phi^n(g) = 1 \}$ are closed subgroups of $L$ (they are closed since they are plaques of a splitting). Stable plaques of $L$ are the left cosets of $L_+$; unstable plaques of $L$ are the left cosets of $L_-$. 

Consider the action of $G$ on $L$ obtained by conjugating by $\Phi$ the action of $G$ on $\mathcal{M}$. The action of its subgroup $G_1 \leq G$ will coincide then with the natural action of $G_1 \leq L$ on $L$ by left multiplication.

The Smale space $(X, f)$ is then topologically conjugate to the homeomorphism induced by $\phi$ on $G \setminus L$.

**Proposition 6.21.** The group $G$ acts on $L$ by affine transformations.

**Proof.** The action of $G_1 \leq G$ on $L$ coincides with the natural left action of $G_1$ on $L$ as a subgroup of $L$. The action of $G$ on $G_1$ by conjugation can be uniquely extended to an action of $G$ on $L$ by automorphism. Denote by $a_g(h)$ for $g \in G$ and $h \in L$ the image of $h$ under the automorphism of $L$ equal to the extension of the automorphism $h \mapsto g h g^{-1}$ of $G_1$.

Let $g \in G$. Then $a_g = g(1) = \Phi^{-1}(g(x_0))$ is an element of $L$. Let us prove that the action of $g$ on $L$ is given by the formula

$$g(x) = a_g(x) \cdot a_g.$$

Consider the map $A_g(x) = a_g^{-1} a_g(x) a_g : L \to L$. Note that if $h \in G_1$, then $A_{h g} = A_g$, since $a_{h g} = h g (1) = h a_g$ and $a_{h g}(x) = h a_g(x) h^{-1}$. It follows that there is a finite number of possibilities for $A_g$, since $G_1$ has finite index in $G$. Note also that $\phi(a_g) = \phi(g(1)) = \phi(g)(1)$ and $\phi(a_g(x)) = \phi(g)(\phi(x))$, so that $\phi(A_g(x)) = A_{\phi(g)}(\phi(x))$.

Suppose that $x \in L_+$. Then $\phi^n(x) \to 1$ as $n \to \infty$. Since the set of possible maps of the form $A_{\phi^n(g)}$ is finite and they are continuous, we have

$$\phi^n(A_g(x)) = A_{\phi^n(g)}(\phi^n(x)) \to 1,$$

i.e., $A_g(x) \in L_+$. Consequently, the maps $A_g$ preserve $L_+$.

If $x, y$ belong to one stable plaque, then $x^{-1} y \in L_+$, hence

$$A_g(x^{-1} y) = (a_g(x) a_g)^{-1} (a_g(y) a_g) \in L_+.$$

Consequently, the affine map $x \mapsto a_g(x) a_g$ preserves the stable plaques of $L$. It is proved in the same way that it preserves the unstable plaques, hence it preserves the local product structure.

Let $h \in G_1$. Then $g h L_+ = gh g^{-1}(gL_+) = a_g(h) a_g L_+$, since $g(L_+)$ is the stable plaque $a_g L_+$ of the point $a_g = g(1)$. By the same argument, $g(h L_-) = a_g(h) a_g L_-$ for all $h \in G_1$.

Let $R \subset L$ be a relatively compact open rectangle such that $G_1 \setminus R = G_1 \setminus L$ and $1 \in R$. Then for every $x \in L_-$ and every $n \in \mathbb{N}$ there exists $g_n \in G_1$ such that $x \in \phi^n(g_n R)$. Note that then distance from $x$ to $\phi^n(g_n L_+)$ is exponentially decreasing with $n$. It follows that the union of the stable plaques of the form $h L_+$ for $h \in G_1$ is dense in $L$. Similarly, the union of the unstable plaques of the form $h L_-$ for $h \in G_1$ is also dense in $L$.

The actions of the maps $x \mapsto g(x)$ and $x \mapsto a_g(x) a_g$ on the stable and unstable plaques of the form $h L_+$ for $h \in G_1$ coincide. Both maps are continuous on $L$ and preserve the direct product structure, hence they are equal. \qed

This finishes the proof of Theorem 6.1. \qed
7. Smale spaces with pinched spectrum

7.1. Splitting.

**Definition 7.1.** Let \((\mathcal{X}, f)\) be a Smale space such that \(\mathcal{X}\) is connected and locally connected. Let \(a_0, a_1\) be the stable lower and upper critical exponents, and let \(b_0, b_1\) be the unstable lower and upper critical exponents.

We say that the Smale space has **pinched spectrum** if

\[
\frac{a_0}{a_1} + \frac{b_0}{b_1} > 1,
\]

**Theorem 7.1.** A Smale space with pinched spectrum is splittable.

**Proof.** Choose numbers \(a_0, a_1, \beta_0, \beta_1\) such that \(0 < \alpha < a_0 \leq a_1 < \alpha_1, 0 < \beta_0 < b_0 \leq b_1 < \beta_1\), and

\[
\frac{a_0}{a_1} + \frac{\beta_0}{\beta_1} > 1.
\]

Let \(d_+\) and \(d_-\) be metrics associated with the internal log-scales \(\ell_+\) and \(\ell_-\) on the stable and unstable leaves of exponents \(a_0\) and \(\beta_0\), respectively. All distances inside the leaves will be measured using these metrics.

Let \(\mathcal{R}\) be a finite covering of \(\mathcal{X}\) by open rectangles. We assume (making the rectangles small enough) that the holonomies inside the rectangles \(R \in \mathcal{R}\) are bi-Lipschitz. Then it follows from equalities (3) and (4) in Section 2 that the holonomies inside \(f^k(R)\) for all \(R \in \mathcal{R}\) and \(k \in \mathbb{Z}\) are bi-Lipschitz with a common Lipschitz constant \(L > 1\).

There exists \(\epsilon > 0\) such that for any \(x \in \mathcal{X}\) there exists a rectangle \(R \in \mathcal{R}\) such that the \(\epsilon\)-neighborhood of \(x\) in \(W_+(x)\) (with respect to \(d_+\)) and the \(\epsilon\)-neighborhood of \(x\) in \(W_-(x)\) (with respect to \(d_-\)) are contained in \(R\). Then, for some constant \(\epsilon > 0\) and for every \(k \in \mathbb{Z}\), \(x \in \mathcal{X}\), there exists \(R \in \mathcal{R}\) such that the \(\epsilon e^{-a_0k}\)-neighborhood of \(x\) in \(W_+(x)\) is contained in \(f^k(R)\), and the \(\epsilon e^{\alpha_0k}\)-neighborhood of \(x\) in \(W_-(x)\) is contained in \(f^k(R)\).

Choose \(x_0 \in \mathcal{X}\). Let us construct a splitting \(\pi_{x_0} : W_+(x_0) \times W_-(x_0) \rightarrow \mathcal{X}\). Let \(x \in W_+(x_0)\), and let \(n\) be a positive integer. Since \(a_1\) is a stable upper exponent, there exists a sequence \(x_0, x_1, \ldots, x_m = x\) of points of \(W_+(x_0)\) such that \(m_1 \leq C_1 e^{a_1(n - \ell_-(x_0, x))}\), and \(\ell_1(x_i, x_{i+1}) \geq n\), for some constant \(C_1\).

Passing to \(d_+\), we get that

\[
m_1 \leq C_2 d_+(x_0, x)^{a_0/a_1} e^{a_1 n}, \quad d_+(x_i, x_{i+1}) \leq C_3 e^{-\alpha_0 n}.
\]

For every \(k \in \mathbb{Z}\) there exist rectangles \(R_{i+1} \in \mathcal{R}\) such that the \(\epsilon e^{-a_0k}\)-neighborhood of \(x_i\) in \(W_+(x_i) = W_+(x_0)\) and the \(\epsilon e^{b_0k}\)-neighborhood of \(x_i\) in \(W_-(x_i)\) belong to \(f^k(R_{i+1})\). If \(\epsilon e^{-a_0k} > C_3 e^{-\alpha_0 n}\), then \(R_{i+1}\) contains \(x_{i-1}\) and \(x_{i+1}\). The last inequality is equivalent to \(k \leq n - r_1\) for some constant \(r_1 \in \mathbb{Z}\). Choose \(k_1 = n - r_1\), and find a sequence of rectangles \(R_{i+1}\) satisfying the above conditions for \(k = k_1\).

Let \(y \in W_-(x_0)\) be such that \(d_+(x_0, y) \leq \epsilon e^{a_0k_1} = C_4 e^{a_0 n}\) (where \(C_4 = e^{-\alpha_0 r_1}\)). Denote \(z_0 = y, z_1 = [x_1, z_0]f^{k_1}(R_{0, 1}), z_2 = [x_2, z_1]f^{k_1}(R_{1, 1}), \ldots\). If all points \(z_0, \ldots, z_{m_1}\) are defined, then we say that \(y\) can be continued to \(x\), and denote \(\pi_{x_0}(x, y) = z_{m_1}\). Note that \(x_0\) can be continued to \(x\) and \(\pi_{x_0}(x_0, x) = x\).

If \(y\) can be continued to \(x\), then, in the above notation,

\[
d_+(z_i, z_{i+1}) \leq L d_+(x_i, x_{i+1}) \leq C_5 e^{-\alpha_0 n},
\]

where \(C_5\) is the same constant as in the previous argument.
hence
\[ d_+(y, \pi_{x_0}(x, y)) \leq C_5 m_1 e^{-\alpha_0 n} \leq C_6 d_+(x_0, x)^{\alpha_1/\alpha_0} e^{(\alpha_1 - \alpha_0)n}. \]

Let \( k_2 \) be such that
\[ ce^{\alpha_0 k_2} \geq C_6 d_+(x_0, x)^{\alpha_1/\alpha_0} e^{(\alpha_1 - \alpha_0)n}, \]
so that for every point \( z \in X \) there exists a rectangle \( R \in \mathcal{R} \) such that the \( C_6 d_+(x_0, x)^{\alpha_1/\alpha_0} e^{(\alpha_1 - \alpha_0)n} \)-neighborhood of \( z \) in \( W_+(z) \) is contained in \( f^{-k_2}(R) \), and the \( ce^{-\beta_0 k_2} \)-neighborhood of \( z \) in \( W_-(z) \) is also contained in \( f^{-k_2}(R) \).

Inequality (14) follows from an inequality
\[ k_2 \geq \frac{\alpha_1}{\alpha_0} \log d_+(x_0, x) + \frac{\alpha_1 - \alpha_0}{\alpha_0} n + s \]
for some constant \( s \). Consequently, we can take
\[ k_2 = \frac{\alpha_1}{\alpha_0} \log d_+(x_0, x) + \frac{\alpha_1 - \alpha_0}{\alpha_0} n + s_1, \]
where \( s_1 > 0 \) is bounded from above.

Let \( n_2 \) be such that \( e_-(z_1, z_2) \geq n_2 \) implies \( d_-(z_1, z_2) \leq ce^{-\beta_0 k_2} \). There exists a constant \( r_2 \) (not depending on \( k_2 \)) such that we can take \( n_2 = k_2 + r_2 \). Let \( y \in W_-(x_0) \). There exists a sequence \( y_0 = x_0, y_1, y_2, \ldots, y_{m_2} = y \) such that
\[ m_2 \leq C_7 d_-(y, x_0)^{\beta_1/\beta_0} e^{\beta_1 n_2}, \quad d_-(y_i, y_{i+1}) \leq ce^{-\beta_0 n_2} \leq ce^{-\beta_0 k_2}. \]

Choose a sequence of rectangles \( R_{i,2} \in \mathcal{R} \) such that the \( ce^{-\beta_0 n_2} \)-neighborhood of \( y_i \) in \( W_-(y_i) = W_-(x_0) \), and the \( ce^{-\alpha_0 n_2} \)-neighborhood of \( y_i \) in \( W_+(y_i) \) are contained in \( f^{-n_2}(R) \).

Suppose that \( y_i \) can be continued to \( x \). Then \( d_+(y_i, \pi_{x_0}(x, y_i)) \leq ce^{\alpha_0 k_2} \leq ce^{\alpha_0 n_2} \), hence \( \pi_{x_0}(x, y_i) \in f^{-n_2}(R_{i,2}) \). Define then a sequence \( z_{0,i} = y_{i+1}, z_{1,i} = [x_1, z_{0,i}] f^1(R_{i,2}), z_{2,i} = [x_2, z_{1,i}] f^1(R_{i,2}), \ldots \). Each of the points \( z_j,i \) will be defined,
provided $d_-(z_{j-1,i}, x_{j-1}) \leq ce^{\beta_0k_1}$. We have an estimate
\[ d_-(z_{j-1,i}, x_{j-1}) \leq C_8(d_-(x_0, y_1) + d_-(y_1, y_2) + \cdots + d_-(y_{j-2}, y_{j-1})) \leq C_8m_2e^{-\beta_0k_2} \leq C_9d_-(y, x_0)^{\beta_1/\beta_0}e^{(\beta_1 - \beta_0)k_2}.
\]
(We used that $n_2 = k_2 + r_1$ for some constant $r_1$.)

It follows that $y$ can be continued to $x$ if
\[ C_9d_-(y, x_0)^{\beta_1/\beta_0}e^{(\beta_1 - \beta_0)k_2} \leq ce^{\beta_0k_1}, \]
i.e., if
\[ (\beta_1 - \beta_0)k_2 + \frac{\beta_1}{\beta_0} \log d_-(y, x_0) + s_2 \leq \beta_0n \]
for some constant $s_2$.

Replacing $k_2$ by the value given in (15), we get that $y$ can be continued to $x$ if
\[ (\beta_1 - \beta_0) \left( \frac{\alpha_1 - \alpha_0}{\alpha_0} n + \frac{\alpha_1}{\alpha_0^2} \log d_+(x_0, x) \right) + \frac{\beta_1}{\beta_0} \log d_-(y, x_0) + s_3 \leq \beta_0n \]
for some constant $s_3$. If
\[ \frac{(\beta_1 - \beta_0)(\alpha_1 - \alpha_0)}{\alpha_0} < \beta_0, \]
then taking $n$ big enough, we can guarantee that inequality (16) is satisfied. Inequality (17) is equivalent to
\[ (\beta_1 - \beta_0)(\alpha_1 - \alpha_0) < \alpha_0\beta_0, \]
i.e., to
\[ \beta_1\alpha_1 < \beta_0\alpha_0 + \beta_1\alpha_0 \iff \frac{\alpha_0}{\alpha_1} + \frac{\beta_0}{\beta_1} > 1. \]

It follows that if the Smale space has pinched spectrum, then every point $y \in W_-(x_0)$ can be continued to every $x \in W_+(x_0)$, and we can define $\pi_{x_0} : W_+(x_0) \times W_-(x_0)$ using the rules described above.

Let us show that the map $\pi_{x_0} : W_+(x_0) \times W_-(x_0) \rightarrow X$ is well defined, i.e., does not depend on the choice of the rectangles $R_{i,1}$ (we did not use the rectangles $R_{i,2}$ in the definition of $\pi_{x_0}$).

It follows from the construction that the map $y \mapsto \pi_{x_0}(x, y)$ is equal to composition of holonomy maps of a sequence of rectangles $R_{i,1} \in f^{k_1}(\mathcal{R})$ for some positive $k_1$.

We also showed that for every $y$, the germ of the map $y \mapsto \pi_{x_0}(x, y)$ is equal to a germ of a holonomy in a rectangle $R_{j,1} \in f^{-n_2}(\mathcal{R})$ for some positive $n_2$.

Note also that given such a sequence $R_{i,1} \in f^{k_1}(\mathcal{R})$ we can find a sequence $R'_{i} \in f^{m}(\mathcal{R})$ such that $m$ is arbitrarily big and the map $y \mapsto \pi_{x_0}(x, y)$ defined by the original sequence $R_{i,1}$ is a restriction of the maps defined by the new sequence $R'_{i}$.

Suppose that $h_i : W_-(x_0) \rightarrow W_-(x)$ for $i = 1, 2$ are compositions of holonomies defined using two sequences $R_{i,1}$, and $R'_{1,i}$. We may assume that both sequences belong to $f^{k_1}(\mathcal{R})$ for some fixed $k_1$. Let $y$ belongs to the domain of both maps $h_i$. We may assume (taking $k_1$ big enough) that $x$ and $y$ belong to connected components of the domains of $h_i$. Then there exists a connected chain of rectangles $R_{2,i} \in f^{-n_2}(\mathcal{R})$, for some $n_2 > 0$, such that restrictions of $h_i$ onto the corresponding plaques of $R_{2,i}$ are equal to holonomies in $R_{2,i}$. It follows then from $h_1(x_0) =$
\[ h_2(x_0) = x \text{ that } h_1(y) = h_2(y). \] Consequently, \( \pi_{x_0} \) is well defined. The map \( \pi_{x_0} \) is obviously a local homeomorphism.

Note that if \( R \in \mathcal{R} \) is such that \( x_0 \in R \), then \( \pi_{x_0} : P_+(R, x_0) \times P_-(R, x_0) \rightarrow R \) coincides with \([\cdot, \cdot]_R\).

Let \((a, b) \in W_+(x_0) \times W_-(x_0)\) be an arbitrary point, and let \( x_1 = \pi_{x_0}(a, b) \).

Then it follows from the definition of the maps \( \pi_{x_1} \) and their uniqueness that
\[
\pi_{x_0}(x, y) = \pi_{x_1}(\pi_{x_0}(x, b), \pi_{x_0}(a, y)).
\]

It follows that \( \pi_{x_0} \) is onto, since its range contains every rectangle \( R \in \mathcal{R} \) intersecting it. It also follows that the map \( \pi_{x_0} \) is a covering, since every point of \( W_+(x_0) \times W_-(x_0) \) has a neighborhood mapped homeomorphically by \( \pi_{x_0} \) to an element of \( \mathcal{R} \).

Another corollary of \([18]\) is that \( \pi_{x_0} \) homeomorphically maps plaques of \( W_+(x_0) \times W_-(x_0) \) to leaves of \( \mathcal{X} \), since \( \pi_{x_1} \) maps the direct factors of \( W_+(x_1) \times W_-(x_2) \) identically onto the leaves \( W_+(x_1) \) and \( W_-(x_1) \). This finishes the proof of the theorem.

\[ \square \]

7.2. Polynomial growth.

Theorem 7.2. Let \((\mathcal{X}, f)\) be a Smale space with pinched spectrum. Then the group of deck transformations of the splitting of \((\mathcal{X}, f)\) has polynomial growth.

Proof. Our proof essentially repeats the proof of the main theorem of \([Br178]\). Let \( \mathcal{R} \) be a finite covering of \( \mathcal{X} \) by open connected rectangles. Let \( \pi : \mathcal{M} \rightarrow \mathcal{X} \) be the splitting constructed in Theorem 7.1, where \( \mathcal{M} = W_+(x_0) \times W_-(x_0) \). Denote by \( \tilde{\mathcal{X}} \) the union of the sets of connected components of \( \pi^{-1}(R) \) for \( R \in \mathcal{R} \).

Consider the graph \( \Gamma \) with the set of vertices identified with \( \tilde{\mathcal{X}} \) in which two vertices are connected if the corresponding sets have non-empty intersection. It is easy to show (see the proof of Proposition 7.2) that the graph \( \Xi \) is quasi-isometric to the Cayley graph of the group \( \mathcal{G} \) of deck transformations of \( \pi \) and has the same growth rate as \( \mathcal{G} \).

Let \( B(r) \) be the set of elements of \( \tilde{\mathcal{X}} \) that are on distance at most \( r \) in \( \Gamma \) from a vertex \( R \in \tilde{\mathcal{X}} \) such that \( (x_0, x_0) \in R \).

Let \( 0 < \alpha_0 < a_0 \leq a_1 < \alpha_1 \) and \( 0 < \beta_0 < b_0 \leq b_1 < \beta_1 \) such that \( a_0/\alpha_1 + \beta_0/\beta_1 > 1 \). Denote by \( d_- \) and \( d_+ \) the metrics of exponents \( \alpha_0 \) and \( \beta_0 \) on the corresponding leaves of \( \mathcal{X} \) and plaques of \( W_+(x_0) \times W_-(x_0) \). (Every plaque of \( \mathcal{M} \) is identified with a leaf of \( \mathcal{X} \) by \( \pi \).)

Take \( R \in B(r) \). Choose a sequence \( R_0 \ni (x_0, x_0), R_1, \ldots, R_m = R \) of elements of \( \tilde{\mathcal{X}} \) forming a chain in \( \Gamma \) of length \( m \leq r \).

We will denote by \([\cdot, \cdot]\) the direct product structure on \( W_+(x_0) \times W_-(x_0) \). Let \( D_- \) and \( D_+ \) be the suprema of the \( d_- \) and \( d_+ \)-diameters of the sets \([y, \cup R_i]\) and \([\cup R_i, y]\) for all \( y \in \cup R_i \) (see Figure 5).

There exists constants \( C_1, C_2 \) not depending on \( r \), and a number \( n = n(r) \) such that \( |n - \log D_-/\beta_0| < C_1 \), and for every point \( y \in \mathcal{M} \) there exists a rectangle \( V \in \mathcal{f}^n(\mathcal{R}) \) such that the \( C_2 e^{-\alpha_0 n} \)-neighborhood of \( y \) in the stable plaque of \( y \) (with respect to \( d_+ \)) and the set \([y, \cup R_i]\) are both contained in \( V \).

It follows that we can find a sequence of rectangles \( V_i \in \mathcal{f}^n(\mathcal{R}) \) of length at most \( C_3 e^{\alpha_1 n} \) such that \( V_i \cap V_{i+1} \neq \emptyset \), the first rectangles in the sequence intersects contains a given point of \( R_{i-1} \cap R_i \), while the last one contains a given point of \( R_i \cap R_{i+1} \).
Consequently, we can find a sequence of rectangles $V_0, \ldots, V_l \in f^n(R)$ of length at most

$$C_3 r e^{\alpha_1 n} \leq C_4 r D_{-}^{\alpha_1/\beta_0}$$

such that $V_i \cap V_{i+1} \neq \emptyset$, $x_0 \in V_0$, $V_m$ contains a point $x \in R = R_m$, and for every $V_i$ there exists a point $z_i \in V_i$ such that $[z_i, \cup R_i] \subset V_i$. Moreover, we may assume that the chain $V_i$ covers any given in advance three point $y_1, y_2, y_3 \in \cup R_i$.

It follows that the $d_+\text{-distance}$ from $[y_1, y_2]$ to $[y_3, y_2]$ is bounded from above by

$$C_5 r D_{-}^{\alpha_1/\beta_0} e^{-\alpha_0 n} \leq C_6 r D_+^{\alpha_1/\beta_0} \frac{\alpha_1-\alpha_0}{\beta_0} = C_6 r D_{-}^{\alpha_1-\alpha_0}.$$

It follows that

$$D_{-} \leq C_6 r D_{+}^{\alpha_1-\alpha_0},$$

and, by the same argument,

$$D_{+} \leq C_7 r D_{-}^{\alpha_1-\alpha_0}.$$

Combining the inequalities, we get

$$D_{+} \leq C_8 r \left( C_7 r D_{+}^{\alpha_1-\alpha_0} \right)^{\frac{\alpha_1-\alpha_0}{\beta_0}} = C_8 r^{1+\frac{\alpha_1-\alpha_0}{\beta_0}} D_{-}^{\frac{(\alpha_1-\alpha_0)(\beta_1-\beta_0)}{\alpha_0 \beta_0}},$$

hence

$$D_{+} \leq C_8 r^{p_+},$$

for $p_+ = \left( 1 + \frac{\alpha_1-\alpha_0}{\beta_0} \right) \left( \frac{\alpha_1}{\alpha_0} + \frac{\beta_1}{\beta_0} - \frac{\alpha_1 \beta_1}{\alpha_0 \beta_0} \right)^{-1}$.

Similarly,

$$D_{-} \leq C_8 r^{p_-},$$

for $p_- = \left( 1 + \frac{\beta_1-\beta_0}{\alpha_0} \right) \left( \frac{\alpha_1}{\alpha_0} + \frac{\beta_1}{\beta_0} - \frac{\alpha_1 \beta_1}{\alpha_0 \beta_0} \right)^{-1}$.

In particular (taking $C_{10} = \max(C_8, C_9)$ and $p = \max(p_+, p_-)$) we have that $d_{-}(x, x_0)$ and $d_{+}(x, x_0)$ are less than $C_{10} r^p$ for any $x \in \bigcup_{R \in B(r)} R$.
Let μ+ and μ− be the SRB measures satisfying the conditions of Theorem 3.6. Let μ be their direct product on \( M = W_+(x_0) \times W_-(x_0) \). Since the measures \( \mu_+ \) and \( \mu_- \) on the leaves of \( \mathcal{X} \) are invariant under holonomies, \( G \) acts by measure preserving transformations on \( M \). It follows that there exist positive constants \( A_1 \) and \( A_2 \) such that

\[
A_1 |B(r)| \leq \mu \left( \bigcup_{R \in B(r)} R \right) \leq A_2 |B(r)|.
\]

By the proven above, the set \( \bigcup_{R \in B(r)} R \) is contained in the direct product of the balls of radius \( C_{10r^{p}} \) with center in \( x_0 \) in \( W_+(x_0) \) and \( W_-(x_0) \). By condition (1) of Theorem 3.6, volumes of these balls are bounded from above by \( C(C_{10r^{p}})^{\eta/\alpha_0} \) and \( C(C_{10r^{p}})^{\eta/\beta_0} \) for some constant \( C \). It follows that \( |B(r)| \) is bounded above by a polynomial in \( r \).

By the Gromov’s theorem on groups of polynomial growth [Gro81], \( G \) is virtually nilpotent. Theorem 5.1 now implies the following description of Smale spaces with pinched spectrum.

**Theorem 7.3.** Every connected and locally connected Smale space with pinched spectrum is topologically conjugate to an infra-nilmanifold automorphism.

8. Mather spectrum of Anosov diffeomorphisms

Let \( f : \mathcal{X} \rightarrow \mathcal{X} \) be a diffeomorphism of a compact Riemann manifold \( \mathcal{X} \). It induces a linear operator \( f_* \) on the Banach space of continuous vector fields by

\[
f_*(\tilde{X})(x) = Df \circ \tilde{X}(f^{-1}(x)).
\]

By a theorem of J. Mather [Mat68], \( f \) is an Anosov diffeomorphism if and only if the spectrum of \( f_* \) does not intersect with the unit circle. It belongs then to the set

\[
\{ z \in \mathbb{C} : \lambda_1 < |z| < \lambda_2 \} \cup \{ z \in \mathbb{C} : \mu_2 < |z| < \mu_1 \},
\]

where \( 0 < \lambda_1 < \lambda_2 < 1 < \mu_2 < \mu_1 \). The tangent bundle \( T\mathcal{X} \) is decomposed then into a direct sum \( W^s \oplus W^u \) such that there exists a constant \( C > 1 \) such that for all vectors \( \tilde{v} \in W^s \), \( \tilde{v} \in W^u \), and for every positive integer \( n \) we have

\[
C^{-1} \lambda_1^n \| \tilde{v}^+ \| \leq \| Df^n \tilde{v}^+ \| \leq C \lambda_2^n \| \tilde{v}^+ \|
\]

and

\[
C^{-1} \mu_2^n \| \tilde{v}^- \| \leq \| Df^n \tilde{v}^- \| \leq C \mu_1^n \| \tilde{v}^- \|.
\]

For more detail, see [Mat68, Bri77, Bri78]. Every Anosov diffeomorphism is a Smale space, see [BS02, Proposition 5.10.1]. Stable and unstable leaves of \( (\mathcal{X}, f) \) are manifolds, and the vectors of \( W^s \) and \( W^u \) are tangent to the stable and unstable leaves, respectively.

**Proposition 8.1.** Let \( \lambda_1, \lambda_2, \mu_1, \mu_2 \) be as above. Then \( \log \mu_2 \) and \( \log \mu_1 \) are unstable lower and upper exponents of \( (\mathcal{X}, f) \), and \( -\log \lambda_2 \) and \( -\log \lambda_1 \) are stable lower and upper exponents of \( (\mathcal{X}, f) \).

**Proof.** It is easy to show that for every fixed \( k_0 \) the metrics \( d_{k_0} \) on leaves \( W_+(x_0) \) and \( W_-(x_0) \) are quasi-isometric to the restrictions of the Riemannian metric of \( \mathcal{X} \).
onto \( W_+(x_0) \) and \( W_-(x_0) \), with the quasi-isometry constants depending only on \( k_0 \) (and \((\mathcal{X}, f))\).

For every stable leaf \( W_+ \) of \((\mathcal{X}, f))\) and all \( x, y \in W_+ \), \( n \in \mathbb{Z} \),

\[
d_0(f^{-n}(x), f^{-n}(y)) = d_n(x, y).
\]

It follows that there exist constants \( C_1 > 1, \Delta > 0 \) such that

\[
C_1^{-1} \tilde{d}_+(f^{-n}(x), f^{-n}(y)) - \Delta \leq d_n(x, y) \leq C_1 \tilde{d}_+(f^{-n}(x), f^{-n}(y)) + \Delta,
\]

where \( \tilde{d}_+ \) is the Riemannian metrics on the stable leaves.

If \( \gamma \) is a curve in the stable leaf connecting \( f^{-n}(x) \) to \( f^{-n}(y) \), then \( f^n(\gamma) \) is a curve connecting \( x \) to \( y \), and

\[
\text{length}(f^n(\gamma)) = \int \left\| \frac{d}{dt} f^n \circ \gamma(t) \right\| \, dt = \int \left\| Df^n \circ \frac{d}{dt} \gamma(t) \right\| \, dt,
\]

hence

\[
C^{-1} \lambda_1^n \text{length}(\gamma) \leq \text{length}(f^n(\gamma)) \leq C \lambda_2^n \text{length}(\gamma),
\]

and

\[
C^{-1} \lambda_1^n \cdot \tilde{d}_+(f^{-n}(x), f^{-n}(y)) \leq \tilde{d}_+(x, y) \leq C \lambda_2^n \cdot \tilde{d}_+(f^{-n}(x), f^{-n}(y)).
\]

It follows that

\[
C_1^{-1} C^{-1} d_+(x, y) \cdot \lambda_2^n - \Delta \leq d_n(x, y) \leq C_1 C \tilde{d}_+(x, y) \cdot \lambda_1^n + \Delta
\]

for all stably equivalent \( x, y \) and all positive \( n \). Then, by Propositions 3.5 and 4.11

\(- \log \lambda_1 \) and \(- \log \lambda_2 \) are upper and lower exponents.

The case of unstable leaves is proved in the same way. \( \square \)

M. Brin considers in \( \text{[Bri77, Bri78, Bri80, BM81]} \) considers Anosov diffeomorphisms such that either

\[
1 + \frac{\log \mu_2}{\log \mu_1} > \frac{\log \lambda_1}{\log \lambda_2} \tag{18}
\]

or

\[
1 + \frac{\log \lambda_2}{\log \lambda_1} > \frac{\log \mu_1}{\log \mu_2} \tag{19}
\]

Note that since \( \frac{\log \mu_2}{\log \mu_1} \) and \( \frac{\log \lambda_1}{\log \lambda_2} \) are both greater than one, each of the inequalities (18) and (19) imply

\[
\frac{\log \lambda_2}{\log \lambda_1} + \frac{\log \mu_2}{\log \mu_1} > 1. \tag{20}
\]

For instance, in the case of (18):

\[
\frac{\log \lambda_1}{\log \lambda_2} + \frac{\log \mu_1}{\log \mu_2} > 1 + \frac{\log \mu_1}{\log \mu_2} = \frac{\log \mu_1}{\log \mu_2} \left( \frac{\log \mu_2}{\log \mu_1} + 1 \right) > \frac{\log \mu_1}{\log \mu_2} \cdot \frac{\log \lambda_1}{\log \lambda_2}.
\]

Multiplying by \( \frac{\log \mu_2}{\log \mu_1} \cdot \frac{\log \lambda_2}{\log \lambda_1} \), we get (20).

Note that if \( a_0 \) and \( a_1 \) are stable lower and upper critical exponents, and \( b_0 \) and \( b_1 \) are unstable lower and upper critical exponents of the Smale space, then

\[- \log \lambda_2 \leq a_0, \quad \text{and} \quad - \log \lambda_1 \geq a_1, \quad \log \mu_2 \leq b_0, \quad \text{and} \quad \log \mu_1 \geq b_1, \]

so that

\[
\frac{\log \mu_2}{\log \mu_1} \leq \frac{a_0}{a_1}, \quad \frac{\log \lambda_2}{\log \lambda_1} \leq \frac{b_0}{b_1},
\]

and therefore

\[
\frac{a_0}{a_1} + \frac{b_0}{b_1} \geq \frac{\log \mu_2}{\log \mu_1} + \frac{\log \lambda_2}{\log \lambda_1}.
\]
Consequently, each of the conditions (18), (19) implies the inequality
\[ \frac{a_0}{a_1} + \frac{b_0}{b_1} > 1, \]
which is the condition of Theorems 7.1 and 7.2. In particular, we conclude that Theorem 7.3 is a generalization of the results of [BMSI].

9. Co-dimension one Smale spaces

We say that a Smale space is of co-dimension one if its stable or unstable leaves are homeomorphic to \( \mathbb{R} \) with respect to their intrinsic topology.

It was proved by Franks [Fra70, Theorem 6.3] that every co-dimension one Anosov diffeomorphism is a linear Anosov diffeomorphism of a torus. Here we prove this statement for all locally connected and connected Smale spaces.

**Theorem 9.1.** A locally connected and connected co-dimension one Smale space is topologically conjugate to a co-dimension one hyperbolic automorphism of a torus \( \mathbb{R}^d / \mathbb{Z}^d \).

**Proof.** Let us show that every co-dimension one locally connected and connected Smale space has pinched spectrum. In fact, we will show that the upper and lower critical exponents of the leaves homeomorphic to \( \mathbb{R} \) coincide. This will obviously imply that \( \frac{a_0}{a_1} + \frac{b_0}{b_1} > 1 \).

Consider the case when the stable leaves are homeomorphic to \( \mathbb{R} \). Let \( \mu_+ \) be the measure on stable leaves described in Theorem 3.6.

Let \( W_+ \) be a stable leaf, and let \( x, y \in W_+ \). Define \( d_+(x, y) = \mu_+(\{x, y\}) \), where \( (x, y) \) is the interval with endpoints \( x \) and \( y \). Then \( d_+(x, y) \) is a metric on \( W_+ \). It is associated with the standard log-scale \( \ell_+ \), by Theorem 3.6.

Let \( \mathcal{R} \) be a finite covering of \( X \) by open rectangles such that their projections onto the stable direction are intervals. Note that for any two plaques of a rectangle \( R \in \mathcal{R} \) are intervals of the same \( \mu_+ \)-measure. Let \( M \) be the maximum of measures of the stable plaques of elements of \( \mathcal{R} \).

Define \( d'_n(x, y) \) for \( x, y \in W_+ \) to be the smallest length \( k \) of a chain \( I_0, I_1, \ldots, I_k \) of plaques of elements of \( \mathcal{R} \) such that \( f^n(I_i) \subset W_+ \) for every \( i = 0, \ldots, k \), \( x \in f^n(I_0) \), \( y \in f^n(I_k) \), and the intersection \( f^n(I_i) \cap f^n(I_{i+1}) \) is non-empty for every \( i = 0, \ldots, k-1 \). Note that then \( (x, y) \subset \bigcup_{i=0}^{k-1} f^n(I_i) \). It is easy to show that \( d'_n \) is uniformly quasi-isometric to the metrics \( d_n \) defined by the standard log-scale on stable leaves.

Let \( \eta \) be as in Theorem 3.6. Then for every such a chain we have
\[ (k + 1)e^{-\eta n} M \geq \sum_{i=0}^{k} \mu_+(f^n(I_i)) = e^{-\eta n} \sum_{i=0}^{k} \mu_+(I_i) \geq \mu_+((x, y)) = d_+(x, y), \]
hence \( k + 1 \geq M^{-1} e^{\eta n} d(x, y) \), i.e., \( \eta \) is a lower stable exponent.

It follows from the Lebesgue’s covering lemma that there exists \( \epsilon > 0 \) such that for every point \( z \in W_+ \) there exists a plaque of an element of \( \mathcal{R} \) containing the \( \epsilon \)-neighborhood of \( z \). Let us order the points of \( W_+ \), identifying it with \( \mathbb{R} \). Then for any \( x, y \in W_+ \), such that \( x < y \) we can find a sequence of plaques \( I_0 = (a_0, b_0), I_1 = (a_1, b_1), \ldots, I_k = (a_k, b_k) \) such that \( x \in f^n(I_0) \), \( y \in f^n(I_k) \setminus f^n(I_{k-1}) \), and \( I_{i+1} \) contains the \( \epsilon \)-neighborhood of \( b_i \). Then \( b_{i+1} > b_i \), and \( d(b_i, b_{i+1}) > \epsilon \), so that
\[ d(x, y) = d(x, b_0) + d(b_0, b_1) + \cdots + d(b_{k-1}, b_k) + d(b_k, y) \geq (k - 1)\epsilon e^{-\eta n}, \]
hence
\[ k - 1 \leq e^{\eta} d(x, y), \]
which implies that \( \eta \) is also an upper stable exponent.

It follows that \( \eta \) is equal to stable lower and upper critical exponents, which shows that the Smale space has pinched spectrum.

The group \( G \) of deck transformations of a splitting of \( \mathcal{X} \) acts on a stable leaf \( W_+(x_0) \cong \mathbb{R} \) by transformations \( x \mapsto [x, x_0] \). This action preserves the measure \( \mu_+ \). Let us identify \((W_+(x_0), \mu_+)\) and \(\mathbb{R}\) with the Lebesgue measure by a measure-preserving homeomorphism. Since \( G \) acts by measure-preserving transformations, the corresponding action of \( G \) on \( \mathbb{R} \) is by transformations of the form \( x \mapsto \pm x + a \) for \( a \in \mathbb{R} \).

The action of \( G \) on \( W_+(x_0) \) is free, since otherwise an unstable leaf is not mapped homeomorphically onto its image in \( \mathcal{X} \). But this implies that \( G \) acts on \( \mathbb{R} \) by translations, hence is torsion-free abelian. Therefore, by Proposition 5.2 and Theorem 6.10, \((\mathcal{X}, f)\) is topologically conjugate to a hyperbolic automorphism of the torus \( \mathbb{R}^d/\mathbb{Z}^d \) for some \( d \).

\[ \square \]
