Abstract

In this paper we analyze the effect of the massive deformation of the ABJM model on the calculation of conductivity of the dual theory. We show that some of the difficulties presented by the dual geometry, in particular the construction of black holes therein, can be at least partially circumvented by adopting a membrane paradigm-like computation of the conductivity, which requires us to know just the effect of the deformation on the horizon of a black hole in AdS\textsubscript{4}. The deformation at the horizon itself is found by first deforming the flat space near the horizon, and then using the corresponding solution near the horizon as initial conditions for the Einstein’s equations. We find the same result, showing an increase in conductivity, using two types of membrane paradigm computations.

1 Introduction

The past decade has seen the gauge/gravity correspondence emerge as a radically new computational paradigm in understanding quantum field theories at strong coupling. While the duality between type IIB superstrings on $AdS_5 \times S^5$ and $\mathcal{N} = 4$ supersymmetric $SU(N)$ Yang-Mills theory remains the canonical example for such strong coupling computations, the recently discovered duality between type IIA superstrings on $AdS_4 \times \mathbb{CP}^3$ and the so-called ABJM model [1], a $(2+1)$-dimensional $\mathcal{N} = 6$, $U(N) \times U(N)$ Chern-Simons-matter theory is quickly gaining ground in popularity. Much of the interest in this version of the duality stems from the utility of the ABJM model in testing various strongly coupled phenomena in planar condensed matter systems. One such application is the relatively poorly understood quantum critical phase that appears at nonzero temperatures around the $T = 0$ transition point between insulators and superconductors (superfluids). Since this system is effectively described by a conformal field theory (see for instance [2] and references therein), it is a prime candidate for application of the AdS/CFT toolbox.

Expanding on this point, the physics of particles (relevant on the insulator side of the transition) or vortices (relevant on the superconducting phase of the transition) suggest different behaviours for the conductivity of the system as a function of frequency, $\sigma(\omega)$. In [3] it was suggested that this situation could perhaps be captured by the gravity dual of the ABJM model by coupling the global $U(1)$ field to the Weyl tensor. Then, depending on the coupling, $\gamma$, one obtains either the particle-like or vortex-like behaviour for $\sigma(\omega)$. However, at nonzero temperatures, the conformal symmetry is broken by the scale $T$ and understanding how this deformation affects quantities like the conductivity is essential. To this end finding a laboratory in which this can be done in a controlled setting that preserves as much of the other symmetries as possible is key.

In this paper we study just such a laboratory, the massive deformation of the ABJM model of [4, 5], that is known to preserve the full $\mathcal{N} = 6$ supersymmetry. We want to generalize the calculation of [3] to include the effect of the mass deformation, however we will find that we can only calculate the DC conductivity, $\sigma(0)$. Even in this limited case though, in order to calculate this, we need to resort to a membrane paradigm-type calculation, similar to the one in [6], and extend its results to a more general set-up. An important technical point is that, in the absence of the exact solution for the black hole in the massive deformation of the gravity dual of ABJM, we need to rely on a perturbative approach to the massive deformation around the horizon of the black hole. We believe that this approach is new, novel and may indeed prove useful in other contexts as well.

The paper itself is organized as follows. In section 2 we review the methods and results of [3]. In section 3 we show that by applying the Kubo formula, only now for a boundary term at the horizon of the AdS black hole, we obtain exactly the same DC conductivity as [3], and then review and generalize another membrane paradigm calculation as defined in [6]. In section 4 we perform the massive deformation of the black hole horizon, by first finding the zeroth and first order deformations, then using the Einstein’s equations
to compute the higher order one. We benchmark our procedure against the known AdS black hole with excellent agreement. Section 5 concerns itself with a calculation of the conductivity using the two versions of the membrane paradigm calculation. We conclude the formal part of the paper with a discussion of future directions in section 6. Following this, in a series of appendices, we elaborate on some of the details omitted in the main text. In Appendix A outlines the T-duality calculation from the type IIB to IIA backgrounds, while in Appendix B we show that the presence of a non-vanishing $g_{rt}$ contribution to the metric, which appears due to the massive deformation, doesn’t affect the formulas for the membrane paradigm calculations with the example of a scalar field. This is then applied, in Appendix C, to the case of the conductivity calculation. Finally, Appendix D, provides the details of the calculation using the Kubo formula at the horizon.

## 2 Conductivity for AdS black holes

To begin, and largely to establish our conventions and notation, let us review quickly the computation of the conductivity associated to a Maxwell field in an AdS black hole background following [3]. Materials possessing a quantum critical phase, like ultracold $^{87}$Rb, exhibit a zero temperature phase transition in terms of the coupling $g$ of the system, between a superconducting phase for $g < g_c$ and an insulator phase for $g > g_c$. Modelling the order parameter of the system as a bosonic (scalar) field, the material is typically described by the action

$$S = \int d^3x \left[ |\partial_\tau \phi|^2 + v^2 |\nabla \phi|^2 + (g - g_c)|\phi|^2 + \frac{n}{2} |\phi|^4 \right].$$

From this action, it is clear that when $g < g_c$, the order parameter $\langle \phi \rangle \neq 0$, resulting in the usual superfluid properties of the material, while when $g > g_c$ we have that $\langle \phi \rangle = 0$, giving an insulator phase. Thus $(g = g_c, T = 0)$ is a critical point of the system, described by a $(2 + 1)$-dimensional conformal field theory. To apply the arsenal of the gauge/gravity correspondence to problems like this, it is assumed that this system is dual to some (quantum) gravitational theory in a one higher dimensional $AdS_4$ space. For example, the $(2 + 1)$-dimensional ABJM model that is the focus of this article, has a gravity dual theory in $AdS_4 \times \mathbb{CP}^3$.

At nonzero temperatures a quantum critical phase opens up\(^1\) around $g = g_c$ and it is expected that the physics of this quantum critical point should be governed by the zero temperature conformal field theory. However, a computation of the frequency-dependent conductivity $\sigma(\omega)$ using a particle/hole description which is generally valid on the insulator side of the phase transition, yields a functional form that decreases to a minimum before stabilizing. On the other hand, a similar computation using a vortex description, valid on the superfluid side of the phase transition, obtains a conductivity that increases to a maximum before stabilizing (see for instance figures 4 and 5 in [2]). There seems to be

\(^1\)See e.g. figure 2 in [2].
no way to choose which behaviour should be realized using field theory arguments. A
semi-phenomenological parameter will be introduced in the gravity dual that will govern
this choice ($\gamma > 0$ for particle-like and $\gamma < 0$ for vortex-like).

The problem appears to be better suited to a dual gravity description. To this end, let’s
consider the gravity dual of the ABJM model reduced to just Einstein-Maxwell gravity in
$AdS_4$ (plus possible terms higher order in curvature and the field strength tensor $F_{\mu\nu}$). If
we consider only terms that vanish on the $AdS_4$ background but that are nonzero in the
$AdS_4$–black hole background corresponding to a finite temperature field theory, there is a
unique contribution to the action: a coupling to the Weyl tensor. With this in mind, the
action for the Maxwell field in the gravity dual can be taken to be

$$S_{\text{vector}} = \frac{1}{g_4^2} \int d^4 x \sqrt{-g} \left[ -\frac{1}{4} F_{\mu\nu} F^{\mu\nu} + \gamma L^2 C_{\mu\nu\rho\sigma} F^{\mu\nu} F_{\rho\sigma} \right], \quad (2.2)$$

in a probe approximation for the background. That is, we consider that the $AdS$ black
hole background is not modified by the gauge field perturbation, and is given by

$$ds^2 = \frac{r_0^2}{L^2 u^2} \left( -f(u) dt^2 + dx^2 + dy^2 \right) + \frac{L^2 du^2}{u^2 f(u)}, \quad (2.3)$$

where

$$f(u) = 1 - u^3, \quad r_0 = \frac{4\pi T L^2}{3}. \quad (2.4)$$

With this in place, the DC conductivity can now be calculated from a membrane-paradigm
like calculation starting from a more general form of the action in (2.2),

$$S = \int d^4 x \sqrt{-g} \left[ -\frac{1}{8g_4^2} F_{\mu\nu} X^{\mu\nu\rho\sigma} F_{\rho\sigma} \right]. \quad (2.5)$$

The action (2.2) corresponds to a choice of

$$X^{\mu\nu\rho\sigma} = 2\delta^{[\mu\nu}[\rho\sigma] - 8\gamma L^2 C_{\mu\nu\rho\sigma}. \quad (2.6)$$

A natural current $j^\mu$ can be defined on the horizon by considering the horizon boundary
term associated with (2.2) and varying it with respect to $A_{\mu}$. Using the equations of
motion, we find the conductivity as the proportionality constant in $j^x = \sigma F_{0x}$, giving

$$\sigma_0 \equiv \sigma(\omega = 0, k = 0) = \frac{1}{g_4^2} \sqrt{-g} \sqrt{-X^{xxt_1 t_1} X^{xxt_2 t_2}} \bigg|_{r = r_H}, \quad (2.7)$$

which leads to

$$\sigma_0 = \frac{1}{g_4^2} (1 + 4\gamma). \quad (2.8)$$

---

2The DC conductivity defined here is at $\omega = 0$; more generally, we will see shortly that the relevant
parameter is $w = \omega/(4\pi T)$, hence the result is valid for $\omega/T \ll 1$. This is the quantity that will be of
interest for us in the remaining sections of the paper.
However, this membrane paradigm calculation is somewhat obscure.\textsuperscript{3} We will return to another membrane-paradigm like computation in the next section, but first, let’s note that one can also do the usual AdS/CFT calculation utilising the Kubo formula,

\[
\sigma(\omega) = -\text{Im} \left( \frac{G_{yy}(q)}{\omega} \right),
\] (2.9)

to calculate the frequency-dependent conductivity. Here \(G_{yy}\) is the 2-point function for the gauge field with \(y\) component, \(A_y\). Defining \(u \equiv r/r_0\), so that \(u = 1\) at the horizon and \(u = 0\) at the boundary, and Fourier transforming gives

\[
A_\mu(t, x, y, u) = \int \frac{d^3q}{(2\pi)^3} e^{iq \cdot x} A_\mu(q, u),
\] (2.10)

where \(q \cdot x = -t\omega + q^x x + q^y y\), with \(q^\mu = (\omega, q, 0)\). The boundary condition at the horizon is

\[
A_y(q, u) = (1 - u)^b F(q, u),
\] (2.11)

at \(u = 1\), with \(F(q, u)\) regular there. To compute the conductivity associated to \(A_y\), we first calculate the action for \(A_y\) on-shell, obtaining the boundary term

\[
S_{yy} = -\frac{1}{2g_4^2} \int d^3x \left[ \sqrt{-g} g^{uu} g^{yy} (1 - 8\gamma \xi L^2 C_{uy}) A_y(u, x) \partial_u A_y(u, x) \right]_{\text{boundary}}.
\] (2.12)

Evaluating this expression on the AdS black hole solution, we get

\[
S_{yy} = -\frac{2\pi T}{3g_4^2} \int d^3x \left[ (1 - u^3)(1 + 4\gamma \xi u^2) A_y(u, x) \partial_u A_y(u, x) \right]_{\text{boundary}}.
\] (2.13)

Considering that the boundary is only at \(u = 0\) (infinity), we obtain

\[
S_{yy} = \frac{2\pi T}{3g_4^2} \int d^3x \left[ A_y(u, x) \partial_u A_y(u, x) \right]_{u=0}
\]

\[
\equiv \int \frac{d^2q}{(2\pi)^3} \frac{1}{2} A_y(-q) G_{yy}(q) A_y(q),
\] (2.14)

where

\[
G_{yy}(\omega, q = 0) = -\frac{4\pi T}{3g_4^2} A_y(u, \omega) \left. \frac{\partial_u A_y(u, \omega)}{A_y(u, \omega)} \right|_{u \to 0}.
\] (2.15)

Substituting this into the Kubo formula then gives

\[
\sigma = \frac{1}{3g_4^2} \text{Im} \left. \frac{\partial_u A_y}{w A_y} \right|_{u \to 0},
\] (2.16)

where \(w \equiv \omega/4\pi T\). Now, the equation of motion for \(A_y\) with sources on the boundary can be solved. Indeed, for small \(w\) (or, equivalently, small \(\omega\)) the solution is found to be

\[
A_y(u) \simeq (1 - u)^{-i\omega} \left[ F_1(u) + w F_2(u) \right],
\] (2.17)
where \( F_1(u) = C \) (constant) and \( F'_2(0) = iC(2 + 12\gamma) \). This, together with the fact that both \( F_1(u) \) and \( F_2(u) \) are well-behaved at the horizon \( u = 1 \), means that

\[
\sigma(\omega \to 0) = \frac{1}{3g_4^2} \text{Im} \left[ i + \frac{F'_2(0)}{F_1(0)} \right] = \frac{1}{3g_4^2} [1 + (2 + 12\gamma)] = \frac{1 + 4\gamma}{g_4^2},
\]

exactly the same as the earlier membrane-paradigm calculation.

In ABJM theory (at \( \gamma = 0 \)), we can find the meaning of \( g_4 \) as follows. The maximally gauged supergravity action in 4 dimensions has a coupling determined by \( L \) and the 4d Newton’s constant \( \kappa^{(4)}_N \),

\[
g_4 \propto \frac{L^{-1}}{\kappa^{(4)}_N} = \frac{\kappa^{(4)}_N}{L}
\]

where the proportionality factor is a numerical constant. Since by compactifying on \( S^7/\mathbb{Z}_k \), with \( L_{S^7} = 2L \),

\[
\frac{1}{[\kappa^{(4)}_N]^{-1}} = \frac{\Omega_7 L_{S^7}}{[\kappa^{(11)}_N]^{2k}} = \frac{\Omega_7 g_s^{-3} l_s^{-9} 2^7 L^7}{k},
\]

where \( \Omega_7 \) is the volume of the unit 7-sphere, we obtain

\[
g_4 \propto g_s^{3/2} k^{1/2} \left( \frac{l_s}{L} \right)^{9/2} \propto \lambda^{1/4} N^{-1}
\]

where in the last equality we wrote \( g_4 \) in terms of field theory parameters using \( L/l_s = 5^{5/4} \sqrt{\pi} \lambda^{1/4} \) and \( g_s = \lambda^{5/4}/N \).

### 3 Membrane paradigm and conductivity from horizon data

In order to extend the computation of the conductivity to the mass-deformed ABJM model, we will first need to modify the above membrane-paradigm computation to account for the fact that we are, as yet, unable to construct a black hole directly in the gravitational dual. The modification itself is easy enough to state; in (2.12), the boundary term was considered to be at \( u = 0 \) (at infinity), whereas now we want to consider the same boundary term at the horizon \( u = 1 \). This is a bit unusual, since it assumes that the sources for the bulk are at the horizon and that, strictly speaking, we have to ignore the normal boundary at \( u = 0 \), since otherwise we get a divergent contribution due essentially to the infinite ratio between the contributions from the two boundaries. Let’s first benchmark this against the above case of the \( \text{AdS}_4 \) black hole to check that we are indeed on the right track before looking for a better justification for it.

For the boundary term at \( u = 1 \) only, from (2.13) we get

\[
S_{yy} = -\frac{2\pi T}{3g_4^2} (1 + 4\gamma) \int d^3x \left[ 3(1-u)A_y(u, \vec{x})\partial_u A_y(u, \vec{x}) \right]_{u\to1},
\]
which leads to
\[
G_{yy}(\omega, q = 0) = -\frac{4\pi T}{3g_4^2}(1 + 4\gamma) \left[ 3(1 - u) \frac{\partial_u A_y(u, \omega)}{A_y(u, \omega)} \right]_{u \to 1}.
\] (3.2)

This expression, together with the Kubo formula (2.9), evaluated at the horizon the approximation \(\partial_u A_y/w \approx i/(1 - u)\) yields
\[
\sigma(\omega \to 0) = \frac{1}{3g_4^2}(1 + 4\gamma) \Im \left[ 3(1 - u) \frac{i}{1 - u} \right] = \frac{1 + 4\gamma}{g_4^2}.
\] (3.3)

Not only is this the same result as the standard membrane paradigm computation but notice also that the factors of \(1 + 4\gamma\) and \(-3\) enter in a completely different way, so it is highly nontrivial that we get the same answer.4

To better understand this result, let’s reconsider the general membrane paradigm analysis carried out in [6] where the same type of current at the horizon as in [3] was considered in the context of the action
\[
S_{em} = -\int_\Sigma d^{d+1}x \sqrt{-g} \frac{1}{4g_{d+1}^2(r)} F_{MN} F^{MN}
\] (3.4)

where \(g_{d+1}(r)\) is an \(r\)-dependent coupling possibly arising from background fields. The bulk action results in a boundary term that can be cancelled by
\[
S_{bd} = \int_\Sigma d^d x \sqrt{-\gamma} \left( \frac{j^\mu}{\sqrt{-\gamma}} \right) A_\mu,
\] (3.5)

where \(j^\mu\) is obtained by varying the action with respect to \(\partial_r A_\mu\), and \(\gamma_{\mu\nu}\) is the induced metric on the stretched horizon \(\Sigma\). The same calculation as in the previous section then leads to
\[
\sigma(\omega \to 0) = \frac{1}{g_{d+1}^2(r_0)^2},
\] (3.6)

which is indeed compatible with (2.7) for \(d = 3\) and \(X_{\mu \nu \rho \sigma} = 2\delta_{[\mu \nu]}^{[\rho \sigma]}\).

The equations of motion of the action (3.4) in a diagonal background
\[
ds^2 = -g_{tt} dt^2 + g_{rr} dr^2 + g_{ij} dx^i dx^j
\] (3.7)

then imply
\[
\partial_r j^i = 0 + O(\omega F_{it}); \quad \partial_t F_{it} = 0 + O(\omega j^i)
\] (3.8)

which in turn mean that the relation
\[
j^i(r_H) = \frac{1}{g_{d+1}^2(r_H)} \sqrt{-g} g^{zz} F_{it}(r_H) |_{r_H}
\] (3.9)

4Also notice that the temperature has cancelled in the calculation of the DC conductivity, which as already explained, is still valid as long as \(\omega/T \ll 1\).
is valid at all \( r \), until infinity, with the same coefficient. Therefore the DC conductivity calculated at the horizon equals the one calculated at infinity, which is the usual AdS/CFT formula, with the result

\[
\sigma(\omega = 0) = \frac{1}{g_{d+1}} \sqrt{-g} \frac{g^{zz}}{g_{rr}g_{tt}} \bigg|_{r_H}
\]  

(3.10)

which matches (3.6) for \( d = 3 \). In order to apply these methods to our action in (2.2), we shall consider the case when we can write, on the background solution,

\[
S = - \int d^4x \sqrt{-g} \left( \frac{1}{4g_{M,N,A}^2(r)} F_{MN} F^{MN} \right).
\]  

(3.11)

Moreover, for the conductivity associated to \( A_y \), we need only the \( F_{ry} \) component to be nonzero in which case, following the membrane paradigm calculation, we obtain,

\[
\sigma(\omega = 0) = \frac{1}{g_{ry,4}^2}
\]  

(3.12)

instead of (3.6) so that (3.8) still holds, implying that the membrane paradigm calculation still matches the AdS/CFT result as was indeed verified for pure ABJM theory. We therefore feel confident in using it for the massive deformation. Having said that, one potential issue could be the fact that we will need to deal with a more general metric background of the form

\[
ds^2 = -g_{tt}(r,t) dt^2 + g_{rr}(r,t) dr^2 + 2g_{rt}(r,t) dr dt + g_{yy}(r)(dx^2 + dy^2)
\]  

(3.13)

However, as we show in Appendix B, the off-diagonal terms do not influence the result. Indeed, we will see shortly that the same is true for the calculation of the conductivity.

We should also point out that an explicit time dependence in the metric, as in (3.13), modifies (3.8) by replacing the “0” on the right hand side of the first equation by time derivatives of the metric (see Appendix C for more details). This would imply that we could not use (3.8) as an argument to show that the conductivity defined at the horizon matches the one defined at the boundary. However, this does not necessarily mean they are different, since the integrated \( r \)-dependence for \( \sigma = j^i / F_{i4} \) could still give the same result at the horizon and the boundary. This is as expected from the validity of AdS/CFT, which is, after all, a relation between the boundary field theory (the conductivity being a boundary observable) and bulk gravitational physics, and the membrane paradigm which implies that the bulk gravitational physics should be describable in terms of just a fictitious membrane at the horizon. Moreover, the time dependence cannot last forever. The metric must “relax” to a stationary one after some time has passed, as expected from general principles of black hole physics. Thus although, in principle, there could be an explicit time dependence in the bulk metric, we can assume this dependence will die out way before we “shake” the system with the gauge fields \( A_\mu^A \) we are using as probes.
4 Massive deformation for ABJM black hole

As alluded to in the introduction to this article, the ABJM model admits a mass deformation that, while obviously breaking its conformal symmetry, preserves its full $\mathcal{N} = 6$ supersymmetry [4, 5]. Unfortunately, the gravity dual to this massive deformation is, to say the least, very complicated (see [7, 8] for more details), and finding an exact black hole solution in this case seems hopeless. What we can do however, is to consider the deformation of the background in which the M2-branes of the ABJM model live. Recall that the pure ABJM model arises from the near-horizon limit of the back-reacted geometry produced by M2-branes moving in the background $\mathbb{R}^{2,1} \times \mathbb{C}^4 / \mathbb{Z}_k$, i.e. 11-dimensional flat space with a $\mathbb{Z}_k$ identification. The background corresponding to the mass-deformed ABJM model is obtained from the maximally supersymmetric pp-wave of type IIB string theory by a sequence of T-dualizing and lifting to M-theory [8, 9]. To add a black hole to this construction is a notoriously difficult task.

4.1 First order deformation near the horizon

Fortunately, as argued earlier, it will suffice for us to consider just a mass-deformation of the horizon of the $\text{AdS}_4$ black hole. To zeroth order, we can consider the horizon of the black hole to be flat, so we can trivially add a pp-wave to it by replacing the flat space with the pp-wave space, in the coordinates around the spherical horizon. The mass deformation is then implemented T-dualizing to obtain a first order solution. To obtain a (back-reacted) solution around the horizon of the black hole with the mass deformation, we will input this first order solution as initial data into the Einstein’s equations, and obtain the required metric and Weyl tensor at the horizon. We will show how to carry this out explicitly in the next subsection and, for now, restrict our attention to obtaining the first order solution to be used as an initial data.

To superpose the pp-wave on to the AdS black hole, we must first obtain flat space in usual Minkowski coordinates. To do that, we will take a near-horizon limit and then perform a double Wick rotation. We detail these steps as follows. The starting point is the $\text{AdS}_4 \times S^7$ black hole metric in Poincaré coordinates

$$ ds^2 = \frac{r^2}{L^2} \left[ - \left( 1 - \frac{r_0^3}{r^3} \right) dt^2 + dx_1^2 + dx_2^2 \right] + L^2 \frac{dr^2}{r^2 \left( 1 - \frac{r_0^3}{r^3} \right)} + L^2 d\Omega_7^2, \quad (4.1) $$

where $\vec{x} = (x_1, x_2)$. Since the near horizon geometry corresponds to $r \sim r_0 \ll r_0, L$, we should also consider $L \Omega_7$ large, and approximate it with the flat $d\vec{y}^2_7$. Changing the radial coordinate $r$ to $\rho \equiv 2\sqrt{r/r_0 - 1}$ and expanding in powers of $\rho$ yields the near horizon geometry,

$$ ds^2_M \simeq \frac{r_0^2}{L^2} \left[ - \frac{3}{4} \rho^2 dt^2 + dx_1^2 + dx_2^2 \right] + \frac{L^2}{3} d\rho^2 + d\vec{y}^2_7. \quad (4.2) $$
Since
\[ g_{tt} = -\frac{3r_0^2}{4L^2} \rho^2, \quad g_{x_1x_1} = \frac{r_0^2}{L^2}, \quad g_{\rho\rho} = \frac{L^2}{3}, \quad (4.3) \]
reducing to string theory on \( x_2 \) and T-dualizing along \( x_1 \) yields
\[ \tilde{g}_{x_1x_1} = \frac{1}{g_{x_1x_1}} = \frac{L^2}{r_0^2}, \]
\[ \tilde{g}_{\rho\rho} = g_{\rho\rho} = \frac{L^2}{3}, \]
\[ \tilde{g}_{tt} = g_{tt} = -\frac{3r_0^2\rho^2}{4L^2}, \quad (4.4) \]
\[ \tilde{\phi} = -\frac{1}{2} \ln \left( \frac{r_0^2}{L^2} \right). \]
The type IIB metric can then be read off as
\[ ds^2_{1IB} = -\frac{3r_0^2}{4L^2} \rho^2 dt^2 + \frac{L^2}{r_0^2} dx_1^2 + \frac{L^2}{3} d\rho^2 + dy_1^2. \quad (4.5) \]
For notational convenience, in what follows, we define the new variables,
\[ \tau \equiv \frac{3r_0}{2L^2} t, \quad \tilde{\rho} \equiv \frac{L}{\sqrt{3}} \rho, \quad \tilde{x}_1 \equiv \frac{L}{r_0} x_1, \quad (4.6) \]
in terms of which,
\[ ds^2_{1IB} = -\tilde{\rho}^2 d\tau^2 + d\tilde{x}_1^2 + d\tilde{\rho}^2 + dy_1^2. \quad (4.7) \]
Wick rotating to \( \tau = i\theta \) yields
\[ ds^2 = \tilde{\rho}^2 d\theta^2 + d\tilde{x}_1^2 + d\tilde{\rho}^2 + dy_1^2. \quad (4.8) \]
Now we Wick rotate back along a Euclidean coordinate by first defining
\[ z_1 \equiv \tilde{\rho} \cos \theta = \tilde{\rho} \cos(-i\tau) = \tilde{\rho} \cosh \tau \quad (4.9) \]
\[ z_2 \equiv \tilde{\rho} \sin \theta = \tilde{\rho} \sin(-i\tau) = -i\tilde{\rho} \sinh \tau. \quad (4.10) \]
and rotating to \( z_2 = -i\tilde{\tau} \), to give the new set of variables
\[ z_1 = \tilde{\rho} \cosh \tau, \quad (4.11) \]
\[ \tilde{\tau} = \tilde{\rho} \sinh \tau. \quad (4.12) \]
Near \( \tau \sim 0 \) we have \( z_1 \sim \tilde{\rho} \) and \( \tilde{\tau} \sim \tilde{\rho} \tau \), so that \( \tilde{\rho} \sim z_1 \) and \( \tau \sim \tilde{\tau}/\tilde{\rho} \). Thus, expanding in powers of \( \tau \)
\[ d\tau^2 = \frac{d\tilde{\tau}^2}{\tilde{\rho}^2} + O(\tau), \quad (4.13) \]
\[ d\tilde{\rho}^2 = dz_1^2 + O(\tau), \quad (4.14) \]
yields
\[ ds^2 = -d\tau^2 + d\bar{x}_1^2 + dz_1^2 + dy_7^2. \] (4.15)

Now that we have the near horizon metric explicitly written as a flat metric, we simply add the pp-wave to the horizon by replacing (4.15) with
\[ ds^2 = -d\tilde{\tau}^2 + d\bar{\tilde{x}}_1^2 - \mu^2 (z_1^2 + y_7^2) (d\tilde{\tau} + d\bar{\tilde{x}}_1)^2 + dz_1^2 + dy_7^2, \] (4.16)
and turning on an \( F_{++} \), where the lightcone coordinate \( x^+ \equiv \bar{x}_1 + \tilde{\tau} = \bar{x}_1 + \bar{\rho}\sinh \tau \) and \( z_1 = \bar{\rho}\cosh \tau \), and the ellipses are three of the \( \vec{y} \). Note that \( \mu \), the mass parameter of the pp-wave added, corresponds in the gauge theory to the mass deformation parameter of the same name, as was argued in [8, 9]. In particular, from the identification in eq. 2.28 of [9] with the calculation of the same quantity in gauge theory, we can see that \( \mu \) is indeed the same parameter. Going back from the \( (z_1, \tilde{\tau}) \) variables to the original \( (\bar{\rho}, \tau) \) ones gives the IIB wave solution
\[ ds^2 = -(d(\bar{\rho}\sinh \tau))^2 + d\bar{x}_1^2 - \mu^2 (\bar{\rho}^2 \cosh^2 \tau + y_7^2) (d(\bar{\rho}\sinh \tau) + d\bar{x}_1)^2 + (d(\bar{\rho}\cosh \tau))^2 + dy_7^2. \] (4.17)

In order to arrive at the desired eleven dimensional metric, we now need to T-dualize it to IIA and then lift it to M-theory. The Buscher rules applied to this metric are displayed in Appendix A and, after some algebra, the resulting type IIA metric turns out to be
\[ ds^2_{IIA} = \frac{1}{1 - \mu^2 (\bar{\rho}^2 \cosh^2 \tau + y_7^2)} \left( -\bar{\rho}^2 d\tau^2 + dp^2 + d\bar{x}_1^2 - \mu^2 (\bar{\rho}^2 \cosh^2 \tau + y_7^2) (d(\bar{\rho}\sinh \tau))^2 + dy_7^2. \right) \] (4.18)

Now, returning to the original \( (\rho, t, x_1) \) variables using (4.6), and defining
\[ H \equiv 1 - \mu^2 \left( \frac{3}{3} \rho^2 \cosh^2 \left[ \frac{3t r_0}{2L^2} \right] + y_7^2 \right) \] (4.19)
puts the type IIA metric above into the form
\[ ds^2_{IIA} = H^{-1} \left[ -\frac{3}{4} \rho^2 dt^2 + \frac{L^2}{3} d\rho^2 + \frac{L^2}{r_0^2} dx_1^2 - (1 - H) \frac{L^2}{3} \left( d \left( \rho \cosh \frac{3t r_0}{2L^2} \right) \right)^2 + dy_7^2. \] (4.20)

Finally, lifting to M-theory gives
\[ ds^2_M = H^{-2/3} \left[ -\frac{3}{4} \rho^2 dt^2 + \frac{L^2}{3} d\rho^2 + \frac{L^2}{r_0^2} dx_1^2 + dx_{11}^2 - (1 - H) \frac{L^2}{3} \left( d \left( \rho \cosh \frac{3t r_0}{2L^2} \right) \right)^2 \right] + H^{1/3} dy_7^2. \] (4.21)

This metric corresponds to mass-deforming the black hole solution, though only near the horizon. We also note that (4.15) only corresponded to the metric near the horizon for
small $\tau$, or equivalently for small $t$, so we will still need to be careful to use it only in black hole calculations in this region.

Having, through considerable ingenuity, obtained the eleven dimensional metric, in order to apply the procedure for calculating conductivity, we first need to dimensionally reduce it to four dimensions with a cosmological constant. The question at hand then is whether we can perform a consistent truncation to four dimensions. The general ansatz for the truncation of the metric on an $n$-sphere $S^n$ down to $d$ dimensions is [10] (here $D = d + n$)

$$ds_D^2 = \Delta^{-\frac{2}{d-2}} ds_n^2 + \Delta^\beta T^{-1}_{AB} dY^A dY^B$$

where

$$\beta = \frac{2}{n-1} \frac{d-1}{d-2},$$

$$\Delta^{2-\beta n} = T^{AB} Y_A Y_B,$$

$$DY^A = dY^A + B^{A B} Y^B.$$ 

Here $Y^A(y)$, with $A = 0, \ldots, n$, the scalar spherical harmonics on the sphere parametrized by $\vec{y}$ intrinsic coordinates, are also coordinates for the Euclidean embedding of the sphere, i.e. $Y^A Y^A = 1$. In our case, $d = 4$, $n = 7$ and $B^{A B} = 0$, giving

$$ds_{11}^2 = \Delta^{-1} ds_n^2 + \Delta^{1/2} T^{-1}_{AB} dY^A dY^B,$$

$$\Delta = (T^{AB} Y_A Y_B)^{-2/3}. \quad (4.24)$$

This also matches with another expression found in [11], for $T_{AB} = X_A \delta_{AB}$, with

$$ds_D^2 = (X_A Y_A^2)^{\frac{2}{d-2}} ds_n^2 + (X_A Y_A^2)^{-\frac{d-3}{d-1}} (X_A^{-1} dY_A^2). \quad (4.25)$$

In our case, both this and the former expressions reduce to:

$$ds_{11}^2 = (X_A Y_A^2)^{2/3} ds_n^2 + (X_A Y_A^2)^{-1/3} X_A^{-1} dY_A^2 \quad (4.26)$$

where $A = 0, \ldots, 7$. The question is whether the metric (4.21) can be described as this kind of consistent truncation to four dimensions on a deformed 7-sphere since we need a metric solving a four dimensional action obtained by consistent truncation. It is easy to see that, in general, it can not. However, as we will now demonstrate, it is possible to do so in a special limit.

The spherical harmonics $Y^A$ are coordinates for the embedding of the sphere in 8-dimensional Euclidean space, i.e. $Y_A Y^A = L^2$. We will consider a small patch of the sphere, namely near the “North Pole”, $Y^0 = L$. Then we can consider an intrinsic parametrization of the sphere, i.e. some set of coordinates $\vec{y}$ which match the $\vec{y}_7$ coordinates in our metric. Taking the $y_i$’s to be small means that the spherical harmonic components are $\vec{Y}_7(\vec{y}_7) \approx \vec{\vec{y}}_7$ so that, from the sphere constraint, we have

$$Y^0 = \sqrt{L^2 - (\vec{Y}_7)^2} \approx \sqrt{L^2 - (\vec{\vec{y}}_7)^2}. \quad (4.27)$$
The factor $\Delta$ in the metric is then
\[ X_A Y_A^2 = X_0 \left( L^2 - (\vec{y}_i)^2 \right) + X_i^2 (y_i^2)^2, \] (4.28)
and, reading off equation from (4.21), this should match with $H^{-1}$. Expanding both sides in powers of $(y_i^2)^2$ and matching coefficients, yields the eight scalars
\[ X_0 L^2 = \frac{1}{1 - \mu^2 \rho^2 L^2 \cosh^2 \left[ \frac{3tr_0}{2L^2} \right]}, \]
\[ X_i^2 = |X_i| = X_0 + \mu^2 (X_0 L^2)^2, \] (4.29)
in four dimensions. Finally then, the four dimensional metric is
\[ ds^2 = -dt^2 \left( \frac{3r_0^2}{4L^2} \rho^2 + \frac{\mu^2 \rho^4 r_0^2}{4} \cosh^2 \left[ \frac{3tr_0}{2L^2} \right] \sinh^2 \left[ \frac{3tr_0}{2L^2} \right] \right) \]
\[ + \rho^2 L^2 \left( 1 - \mu^2 \frac{L^2}{3} \rho^2 \cosh^4 \left[ \frac{3tr_0}{2L^2} \right] \right) \]
\[ - \mu^2 r_0 L^2 \rho \cosh \left[ \frac{3tr_0}{2L^2} \right] \sinh \left[ \frac{3tr_0}{2L^2} \right] + \frac{L^2}{r_0^2} dx^2 + dx_{11}^2. \] (4.30)

Some points about this metric deserve further clarification. Obviously, as we claimed earlier, (4.21) is not of the reduced type (4.26). However, because the two match up to quadratic order in the internal $y$ coordinates, there is a solution that looks like the reduction ansatz (4.26) and whose four-dimensional metric is a small perturbation of (4.32). We also note that we only need to define the (arbitrary) initial solution on a Cauchy surface, and so we needn’t worry about satisfying the exact equations of motion for the initial solution that we define here.

Returning to the original coordinate $u$ with $\rho = 2(1/u - 1)^{1/2}$, we have
\[ ds^2 = ds^2_{AdS_4BH} + \mu^2 ds^2_{MD}, \] (4.31)
where
\[ ds^2_{MD} = -dt^2 r_0^2 \left( 1 - u \right)^2 a^2 \cosh^2 \left[ \frac{3tr_0}{2L^2} \right] \sinh^2 \left[ \frac{3tr_0}{2L^2} \right] - du^2 \frac{4L^4}{9a^4} \cosh^4 \left[ \frac{3tr_0}{2L^2} \right] \]
\[ - du dt \frac{8L^2 r_0 (1 - u)}{3a^3} \cosh \left[ \frac{3tr_0}{2L^2} \right] \sinh \left[ \frac{3tr_0}{2L^2} \right]. \] (4.32)

This metric (4.31) is our first order solution that we now employ as the initial data to the Einstein’s equations to obtain the back-reacted metric and Weyl tensor at the horizon subject, of course, to the caveat that the solution corresponds to the mass deformation of the horizon only near $t = 0$.

Note that we now have a metric with scalars turned on near the horizon. Thus, our Einstein-Maxwell action with the Weyl coupling term needs to be further modified in order

\[
^5\text{Note that the equations of motion only involve second derivatives, hence in the neighbourhood of the North Pole we only need to have the solution up to quadratic order in } y \text{ in order to satisfy them.}
\]

12
to account for the backreaction of the scalar fields. As argued in the introduction, we do not have the luxury of having an exact black hole solution for the gravity dual of the mass-deformed ABJM theory. What we do have, however, is the leading order mass deformation at the horizon, sourced by the scalars $T_{AB}$, which is sufficient to compute the membrane DC conductivity.

In order to find the correct coupling of the scalars to gravity and the Maxwell fields, we focus on the bosonic part the of the four-dimensional gauged supergravity action. We are therefore led to consider the action

$$I = \int d^4x \sqrt{-g} \left[ R - \frac{1}{2} m^2 \left( \text{Tr}(T)^2 - 2 \text{Tr}(T^2) \right) - \frac{1}{4} \text{Tr} \left( \partial_\mu T^{-1} \partial^\mu T \right) 
+ \frac{1}{g_s^2} \left( - \frac{1}{4} T_{AB} F^A_{\mu\nu} F^{B\mu\nu} + \gamma L^2 C_{\mu\nu\rho\sigma} F^A_{\mu\nu} F^{A\rho\sigma} \right) \right] \quad (4.33)$$

with $T_{AB} \equiv L^2 X_A \delta_{AB}$, with $A = 0, \cdots, 7$. The $L^2$ factor is included in the definition of the $T_{AB}$ fields for dimensional reasons. We close this subsection by writing down the Einstein’s equations that follow from the action (4.33) which we will use to compute the membrane conductivity. Recalling that we are considering the situation where the gauge fields are taken as probes, that is, that the putative black hole background is not modified by the gauge perturbation, the Einstein’s equations that follow from (4.33) are:

$$R_{\mu\nu} = \mathcal{T}_{\mu\nu} - \frac{1}{2} g_{\mu\nu} \mathcal{T}, \quad (4.34)$$

where the energy momentum tensor $\mathcal{T}_{\mu\nu}$ given by

$$\mathcal{T}_{\mu\nu} = \frac{1}{8} \text{Tr} \left( \partial_\mu T^{-1} \partial_\nu T + \partial_\nu T^{-1} \partial_\mu T \right) - g_{\mu\nu} U, \quad (4.35)$$

with $\mathcal{T} = \mathcal{T}^{\mu}{}_{\mu}$, and

$$U \equiv \frac{1}{4} m^2 \left( \text{Tr}(T)^2 - 2 \text{Tr}(T^2) \right) + \frac{1}{2} \text{Tr} \left( \partial_\rho T^{-1} \partial^\rho T \right). \quad (4.36)$$

As a final remark we should also give the relation between the parameter $m^2$ and the $AdS$ scale $L$. The most straightforward way to understand this relation is to compare the Ricci scalars of the pure $AdS_4$ black hole and the mass-deformed one. In the pure case, $R = 4\Lambda = -12/L^2$, whereas with the mass deformation turned on, we have $R = -\mathcal{T}$. In the $\mu \to 0$ limit, from (4.29) we have that $T_{AB} \to \delta_{AB}$, giving $R \to 48 m^2$. Since this has to match with $-12/L^2$, we obtain

$$m^2 = - \frac{1}{4L^2}. \quad (4.37)$$

$^6$Note that this squared-mass is well above the Breitenlohner-Freedman bound.
4.2 Integrating the Einstein’s equations to get higher order deformations

Now that we have obtained a first order solution, we need to use the Einstein’s equations to find the required second- and higher-order solution near the horizon. Indeed, in the action (2.2), we have not just the near-horizon metric, but the Weyl tensor as well, containing second order derivatives of the metric. To specify a solution of the Einstein’s equations, which are second order differential equations, we need to specify the metric and its first derivative (in a non-tangential direction) on a codimension-one Cauchy surface. Therefore, if the coordinate away from the surface, i.e. the foliation direction, is called $v$, and the surface is at $v = 0$, we need to specify the two sets of functions $g_{\mu\nu}(\vec{x}, v = 0)$ and $\partial_v g_{\mu\nu}(\vec{x}, v = 0)$, with $\vec{x}$ coordinates tangent to the Cauchy surface. Then the Einstein’s equations determine the full solution by integration, and in particular, we can obtain at least some of the second order derivatives algebraically (without the need to integrate them). We are accustomed with the situation when $v$ is actually time, and we use a time foliation such that the Cauchy surface is at $t = 0$, but in our case we are actually interested in the situation when $v$ is the radial direction away from the horizon, $\rho$, and the Cauchy surface is at the horizon, $\rho = 0$.

This situation is a bit subtle, since components of the metric are actually divergent or zero at the horizon, hence to check that we are applying it correctly, we first test it on an example when we actually know the full solution, the AdS black hole of (2.3). We will keep only the zeroth and first order solution, and deduce the second order, and in particular the Weyl tensor, from the Einstein’s equations.

As mentioned before, we already know the full metric (2.3), but we will take it in the near horizon limit ($u \to 1$) and its first derivative as the only information given. Note however, that $g_{tt}$ is zero at the horizon, whereas $g_{rr}$ is infinite. So we have non-zero components of the metric that behave as

$$g_{\alpha\beta} = \frac{g^{(-1)}_{\alpha\beta}}{(u - 1)} + g^{(0)}_{\alpha\beta} + g^{(1)}_{\alpha\beta}(u - 1) + \mathcal{O}(u - 1)^2, \quad (4.38)$$

The first derivatives with respect to the coordinate $u$ will be denoted with a prime ($g'_{\alpha\beta}$). In this case therefore we see that giving the metric and its first derivative (as functions of the remaining coordinates) on a Cauchy surfaces needs to be replaced by giving the first two coefficients. For $g_{rr}$ this means $g^{(-1)}$ and $g^{(0)}$, whereas for the rest it is $g^{(0)}$ and $g^{(1)}$. We should also comment on a more general case (even though we are not aware of such examples for the Einstein-Hilbert action): if it happens that some component starts at Laurent expansion order $g^{(-p)}$, we would give $g^{(-p)}$ and $g^{(-p+1)}$, whereas if it starts at $g^{(p)}$, we would need to specify at least $g^{(p)}$ ($g^{(p-1)} = 0$ could be a valid specification, depending on the case at hand). In the case of the AdS black hole test solution, we will take these first two coefficients in the components of $g_{\alpha\beta}$ as known, but we will use their explicit expressions just at the end of the calculations.

For the Einstein’s equations, and later for the Weyl tensor, the primary ingredient is the Riemann tensor. It is practical to write the Riemann tensor with the second derivatives
of the metric explicitly identified, that will make solving of the algebraic equations simpler.

The expression for the Riemann tensor that will be used is

\[ R_{\alpha\beta\gamma\delta} = \frac{1}{2} \left( \partial_{\alpha\delta} g_{\beta\gamma} - \partial_{\alpha\gamma} g_{\beta\delta} + \partial_{\beta\gamma} g_{\alpha\delta} - \partial_{\beta\delta} g_{\alpha\gamma} \right) + \Gamma^\epsilon_{\alpha\delta} \Gamma_{\beta\epsilon\gamma} - \Gamma^\epsilon_{\alpha\gamma} \Gamma_{\beta\epsilon\delta}, \]  

(4.39)

where, by definition, the Christoffel symbols contain first derivatives only.

Let us recall the Einstein equations with a cosmological constant and extract one piece of information before the full calculation. They are

\[ R_{\alpha\beta} - \frac{1}{2} g_{\alpha\beta} R + g_{\alpha\beta} \Lambda = 0. \]  

(4.40)

We can take the trace in the previous equation and obtain the curvature scalar without major effort. In four dimensions it is \( R = 4\Lambda \). For the full metric the Ricci scalar is \( -\frac{12}{L^2} \), and combining these last two expressions yields \( \Lambda = -\frac{3}{L^2} \).

The Ricci tensor is now

\[ R_{\alpha\beta} = \Lambda g_{\alpha\beta}, \]  

(4.41)

which contains inside the second derivatives of the metric (so from here we will have our algebraic equations) and can also be used to calculate the Schouten tensor. In four dimensions, the Schouten tensor has the following expression

\[ S_{\alpha\beta} = \frac{1}{2} \left( R_{\alpha\beta} - \frac{R}{6} g_{\alpha\beta} \right). \]  

(4.42)

Using the Einstein’s equations here will lead to \( S_{\alpha\beta} = \frac{\Lambda}{6} g_{\alpha\beta} \). The Schouten tensor is useful in this case to simplify the calculation of the Weyl tensor (it also contains all the matter information, as we will see later), which can be written as

\[ C_{\alpha\beta}^{\gamma\delta} = R_{\alpha\beta}^{\gamma\delta} - 4S_{[\alpha \delta]}^{[\gamma \beta]}. \]  

(4.43)

Let us calculate the Weyl tensor component \( C_{uy}^{uy} \) that was used to obtain the conductivity in the massless case. Here we have

\[ C_{uy}^{uy} = R_{uy}^{uy} - \frac{\Lambda}{3}. \]  

(4.44)

The Einstein’s equations will play its role here as the relation to find \( R_{uy}^{uy} \) algebraically. We will have to look at the equation for the component \( R_{yy} \) of the Ricci tensor,

\[ R_{yy} = g^{tt} R_{tyty} + g^{uu} R_{uyuy} + g^{xx} R_{xyxy}. \]  

(4.45)

We go then to equation (4.41) for \( R_{yy} \), and rising the \( y \) index we obtain

\[ R_{uy}^{uy} = \Lambda - g^{yy} \left( g^{tt} R_{tyty} + g^{xx} R_{xyxy} \right). \]  

(4.46)

Using (4.39) and the assumption that we have a static and spherically symmetric black hole solution – which is in fact true for the full solution (2.3) –, we see that \( R_{uy}^{uy} \), and therefore
$C_{uy}^{uy}$, are determined solely in terms of the metric and its first derivatives. After adding everything up and replacing the respective values of the metric and its first derivatives, we have the following expression for the sought Weyl tensor component

$$C_{uy}^{uy} = -\frac{1}{2L^2} + O(1 - u),$$  \hspace{1cm} (4.47)

in the near horizon limit. This is in complete agreement with the result one obtains from the full solution (2.3) given by

$$C_{uy}^{uy} = -\frac{u^3}{2L^2}. \hspace{1cm} (4.48)$$

### 4.3 The higher order deformation at the horizon

We now move to apply the procedure defined and tested in the last subsection to our four dimensional mass-deformed metric near the horizon of the black hole.

This case will present more ingredients than the previous one, but the method to obtain the second derivatives is applied in the same way. The massive deformation for the AdS$_4$ black hole enters in the metric like

$$ds^2 = ds^2_{AdS_4-BH} + \mu^2 ds^2_{MD}$$  \hspace{1cm} (4.49)

where $ds^2_{AdS_4-BH}$ is the near horizon expansion of the form (4.38) of (2.3) and the massive deformation is given in (4.32).

Now the desired component of the Weyl tensor is $C^{uyuy}$ (see eq.(C.14)) which, written in terms of the Riemann and Schouten tensors components is

$$C^{uyuy} = (g^{yy})^2 \left( (g^{uu})^2 R_{uyuy} + 2g^{uu} g^{tu} R_{tyuy} + (g^{tu})^2 R_{tyty} \right) - g^{yy} \left( g^{uu} (S_u^u + S_y^y) + g^{tu} S_t^u \right).$$  \hspace{1cm} (4.50)

Like in the previous case, assuming also that we have spherical symmetry in the full solution (i.e. the metric does not depend on $y$, nor $x$) only the $R_{uyuy}$ component involves the second derivatives $\partial^2_{uy} g_{yy}$; the other components $R_{tyuy}$ and $R_{tyty}$ only contain the metric and its first derivatives.

But there is a caveat: we need to assume that $g_{yy}$ is $t$-independent in the full solution, not only in the Cauchy solution, if not, we could have unknown second time derivatives of the metric to calculate as well. We believe however that these are reasonable assumptions, though at this moment we cannot rigorously prove them.

The Einstein’s equations (4.34) now involve an energy-momentum tensor. From those equations we will now obtain the Schouten tensor, that will capture just matter content

$$S_{\alpha\beta} = \frac{1}{2} \left( \mathcal{T}_{\alpha\beta} - \frac{1}{3} \mathcal{T} g_{\alpha\beta} \right).$$  \hspace{1cm} (4.51)
Let us write again the Ricci tensor component that we need for this case,

$$ R_{yy} = g^{tt} R_{tyty} + g^{uu} R_{uyuy} + 2 g^{tu} R_{tyuy} + g^{xx} R_{xyxy}. $$  (4.52)

From here we see that the combination $g^{uu} R_{uyuy} + 2 g^{tu} R_{tyuy}$, that also appears in the Weyl tensor (4.50), can be written in terms of $R_{tyty}$ and $R_{xyxy}$ which do not involve any second derivatives of the metric; so only these two components need to be computed. Thus, we have managed to write $C^{uyuy}$ completely in terms of the metric and its first derivatives as desired.

Making all the replacements in (4.50) the component for the mass deformed Weyl tensor in the near horizon limit reads

$$ C^{uyuy} = \left( \frac{3}{2r_0^2 L^2} + \frac{\mu^2}{2r_0^2} \right) (u - 1). $$  (4.53)

As a consistency check we see that, after using (2.3) also, the $\mu \to 0$ limit above gives the correct answer for the massless case (4.47).

5 Conductivity of the mass-deformed system

We finally return to the calculation of the conductivity. There are two (equivalent) ways to calculate it using the membrane paradigm, as we saw in section 3: one, using a version of Kubo’s formula at the horizon, and the other using formula (3.12), obtained by adding a surface term involving the current.

There is one more observation to be made: the conductivity is usually defined with respect to a $U(1)$ (abelian) field, whereas we have an $SO(8)$ (nonabelian) field, so the conductivity will depend on how we embed the abelian field inside $SO(8)$. In principle there are many ways to do this but we saw that, due to our approximation of being near the North Pole of the $S^7$ of the compactification that generates $SO(8)$, the diagonal gauge field associated with $X^0$ ($A^0$, for index $A = 0$) is special, and different than the diagonal gauge fields associated with $X^i$ ($A^i$, for $A = i$). At the horizon, the $X^i$ scalars “feel” the massive deformation while the $X^0$ field does not (see equation (5.2)).

From section 3, it follows that we need only compute the effective coupling $g_{r_y A}$ at the horizon (see eq. 3.11) with the mass deformation now turned on. In this case,

$$ g^{uu} = \frac{3(1 - u)}{L^2} + \mathcal{O}(1 - u)^2, \quad g^{yy} = \frac{L^2}{r_0^2} + \mathcal{O}(1 - u), $$

$$ C^{uyuy} = \left( \frac{3}{2r_0^2 L^2} + \frac{\mu^2}{2r_0^2} \right) (u - 1) + \mathcal{O}(1 - u)^2, $$  (5.1)

$$ X_0 = \frac{1}{L^2} + \mathcal{O}(1 - u), \quad X_i = \frac{1}{L^2} + \mu^2 + \mathcal{O}(1 - u), $$

near the horizon. Concentrating on the gauge field part of the action (4.33), for $T_{AB} =$
$L^2 X_A \delta_{AB}$, the terms involving $F_{ry}$ are

$$-\frac{1}{4} \int d^4 x \sqrt{-g} F^A_{ry} F^{A,ry} \left[ L^2 X_A - 8 \gamma C^{ry}_{ry} \right].$$

(5.2)

Therefore using (3.12) and the near horizon behavior listed in equations (5.1) through (5.2), we find that

$$\sigma^{(0)} = \frac{1}{g_A^2} \left( 1 + 4 \gamma + 28 \gamma \mu^2 L^2 \right)$$

(5.3)

$$\sigma^{(i)} = \frac{1}{g_A^2} \left( 1 + \mu^2 L^2 + 4 \gamma \left( 1 + 7 \mu^2 L^2 \right) \right),$$

(5.4)

where the (0) and (i) superscripts on the left hand side denote the conductivities associated with the $A^0_\mu$ and $A^i_\mu$ gauge fields respectively.\(^7\) One potential problem that we alluded to earlier was that now we also have a non-vanishing off-diagonal term in the metric $g_{rt}$. However, as we show in Appendix B, its effects cancel each other out at the horizon and do not contribute in the case of a scalar field. In Appendix C, we go one step further and show also that in the case of the gauge field, the above calculation for the conductivity goes through without modification due to a similar type of cancellations that occur at the horizon. Notice also that since $X^0$ does not “see” the mass deformation at the horizon, $\sigma^{(0)}$ is blind to the effect of $\mu^2$ as we turn off the Weyl coupling $\gamma$.

Finally, we can use the Kubo formula for the boundary term at the horizon, just as in the $\mu = 0$ case. Here, we have $X^{uyty}$ nonzero in the background, so the action for the $A_y$ field is now

$$S_{yy} = -\frac{1}{2g_A^2} \int d^3 x \sqrt{-g} \left( X^{uyuy} A_y \partial_u A_y + X^{uyty} A_y \partial_t A_y \right) \bigg|_{u \to 1}.$$

(5.5)

As before, the associated Green’s function

$$G_{yy}^{(A)} = -\frac{3r_0}{L^2 g_A^2} \left( 1 + 4 \gamma + h_A(\mu^2) \right) \left( 1 - u \right) \frac{\partial_u A^A_y(\omega)}{A^A_y(\omega)} \bigg|_{u \to 1},$$

(5.6)

where the index $A$ is used to describe the gauge field whose conductivity we are calculating, leading to

$$h_0(\mu^2) = 28 \gamma \mu^2 L^2$$

$$h_k(\mu^2) = \mu^2 L^2 + 28 \gamma \mu^2 L^2.$$

\(^7\)Note that $\mu$ corresponds exactly to the mass parameter in the gauge theory, as already noted. Then in the gauge theory, the corrections to the dimensionless conductivity (defined at zero frequency and momentum) must also come in a dimensionless combination of $\mu$ and a quantum scale in the nonconformal massive ABJM theory, corresponding to $L$, just like in the ”hard-wall” model for QCD of Polchinski and Strassler, and in other theories with a mass gap that are conformal in the UV, $L$ corresponds to $\Lambda_{QCD}^{-1}$. Also, $g_A$ was related to gauge theory parameters in (2.21) and $\gamma$ is a semi-phenomenological parameter from the point of view of gauge theory.
The equation of motion for $A_y$ near the horizon is then
\[
\frac{\partial_u A_y(\omega)}{A_y(\omega)} \bigg|_{u \to 1} = i\omega \frac{L^2}{3r_0} \frac{1}{1 - u} + i\omega O((1 - u)^0). \tag{5.8}
\]
Consequently then,
\[
\sigma^{(A)} = \frac{1}{g_4^2} \left( 1 + 4\gamma + h_A(\mu^2) \right). \tag{5.9}
\]
More details of this computation may be found in Appendix D.

\section{Conclusions}

To summarize then, in this article we have analyzed the effect of a massive deformation of the ABJM model on the conductivity calculated from the gravity dual. However, unlike the computation in [3], since we don’t have the full $A_y$ defined from the horizon to the boundary, nor even an explicit formula for the gravity dual, we need to use membrane paradigm-type calculations. In particular we have developed a novel calculation based on an extension of the Kubo formula, only using a boundary term at the horizon, together with a corresponding extension of the membrane paradigm method presented in [6].

Crucial to a computation of the conductivity is knowledge of the mass-deformed black hole solution. However, given the complications of the background dual to the mass-deformed ABJM model, such an exact solution remains unknown. Nevertheless, we were able to compute the conductivity knowing only the effect of the mass deformation on the near horizon region of the $\text{AdS}_4$ black hole. In order to determine the mass deformation of the solution near the horizon, we employed a two-step process: First, we input the zeroth and first order solutions as Cauchy data in the Einstein equations, and to find the correct ones that correspond to the mass deformation, superposed a pp-wave on the (approximately flat) horizon and T-dualized. Then, in order to find the higher order solution near the horizon, we developed a method of using Einstein’s equations and the Cauchy data. This procedure was benchmarked against the known AdS black hole solution with excellent agreement. Finally, we obtained the same value for the mass-deformed DC conductivity using both membrane paradigm calculations, with both exhibiting an increase as a function of $\mu^2$.

Of course, given the motivation for this work, we would have wanted to obtain $\sigma(\omega)$ at nonzero $\mu$, with the hope that the mass deformation could replace the deformation by the Weyl tensor coupling $\gamma$ at least in some regime (which should include $\mu \ll T$ so that we still have an approximate conformal field theory at finite temperature). But, due to the technical complications of the background geometry illustrated above, we could only calculate the DC conductivity, $\sigma(0)$. In that respect, all we are able to say is that the mass deformation gives a positive contribution, like a positive $\gamma$, but are unable to speculate any further on what happens at nonzero $\omega$. It goes without saying that it would be of enormous interest to extend the calculation to finite $\omega$ in the future.

A T-duality from IIB to IIA

In this appendix we will give a few details of the T-dualization of the mass-deformed metric. Expanding out the differentials in (4.17), the nonzero components of the metric are:

\begin{align}
g_{\tau \tau} & = -\rho^2 (1 + \mu^2 \cosh^2 \tau (\dot{\rho}^2 \cosh^2 \tau + y_1^2)) \\
g_{\bar{x}_1 \bar{x}_1} & = 1 - \mu^2 (\dot{\rho}^2 \cosh^2 \tau + y_1^2) \\
g_{\rho \bar{\rho}} & = 1 - \mu^2 \sinh^2 \tau (\dot{\rho}^2 \cosh^2 \tau + y_1^2) \\
g_{\rho \tau} & = -\mu^2 \dot{\rho} \cosh \tau \sinh \tau (\dot{\rho}^2 \cosh^2 \tau + y_1^2) \\
g_{\bar{x}_1 \tau} & = -\mu^2 \dot{\rho} \cosh \tau (\dot{\rho}^2 \cosh^2 \tau + y_1^2) \\
g_{\rho \bar{x}_1} & = -\mu^2 \sinh \tau (\dot{\rho}^2 \cosh^2 \tau + y_1^2)
\end{align}

Now we will T-dualize on the $\bar{x}_1$ direction to IIA, application of the Buscher rules yields

\begin{align}
\tilde{g}_{\bar{x}_1 \bar{x}_1} & = 1/g_{\bar{x}_1 \bar{x}_1} = \frac{1}{1 - \mu^2 (\dot{\rho}^2 \cosh^2 \tau + y_1^2)} \\
\tilde{g}_{\tau \tau} & = g_{\tau \tau} - (g_{\tau \bar{x}_1})^2/g_{\bar{x}_1 \bar{x}_1} = -\dot{\rho}^2 (1 + \mu^2 \sinh^2 \tau (\dot{\rho}^2 \cosh^2 \tau + y_1^2)) \frac{1 - \mu^2 (\dot{\rho}^2 \cosh^2 \tau + y_1^2)}{1 - \mu^2 (\dot{\rho}^2 \cosh^2 \tau + y_1^2)} \\
\tilde{g}_{\rho \bar{\rho}} & = g_{\rho \bar{\rho}} - (g_{\rho \bar{x}_1} g_{\bar{x}_1 \tau})/g_{\bar{x}_1 \bar{x}_1} = 1 - \mu^2 \cosh^2 \tau (\dot{\rho}^2 \cosh^2 \tau + y_1^2) \frac{1 - \mu^2 (\dot{\rho}^2 \cosh^2 \tau + y_1^2)}{1 - \mu^2 (\dot{\rho}^2 \cosh^2 \tau + y_1^2)} \\
\tilde{g}_{\rho \tau} & = g_{\rho \tau} - (g_{\rho \bar{x}_1} g_{\bar{x}_1 \tau})/g_{\bar{x}_1 \bar{x}_1} = -\mu^2 \dot{\rho} \cosh \tau \sinh \tau (\dot{\rho}^2 \cosh^2 \tau + y_1^2) \frac{1 - \mu^2 (\dot{\rho}^2 \cosh^2 \tau + y_1^2)}{1 - \mu^2 (\dot{\rho}^2 \cosh^2 \tau + y_1^2)} \\
\tilde{\phi} & = -\frac{1}{2} \log |g_{\bar{x}_1 \bar{x}_1}| = -\frac{1}{2} \log (1 - \mu^2 (\dot{\rho}^2 \cosh^2 \tau + y_1^2)) \\
B_{\bar{x}_1} & = g_{\tau \bar{x}_1} / g_{\bar{x}_1 \bar{x}_1} = -\mu^2 \dot{\rho} \cosh \tau (\dot{\rho}^2 \cosh^2 \tau + y_1^2) \frac{1 - \mu^2 (\dot{\rho}^2 \cosh^2 \tau + y_1^2)}{1 - \mu^2 (\dot{\rho}^2 \cosh^2 \tau + y_1^2)} \\
B_{\rho \bar{x}_1} & = g_{\rho \bar{x}_1} / g_{\bar{x}_1 \bar{x}_1} = -\mu^2 \sinh \tau (\dot{\rho}^2 \cosh^2 \tau + y_1^2) \frac{1 - \mu^2 (\dot{\rho}^2 \cosh^2 \tau + y_1^2)}{1 - \mu^2 (\dot{\rho}^2 \cosh^2 \tau + y_1^2)}.
\end{align}

Then, the mass-deformed metric on type IIA has the following form:

\begin{align}
ds_{IIA}^2 & = \frac{1}{1 - \mu^2 (\dot{\rho}^2 \cosh^2 \tau + y_1^2)} \left( -\dot{\rho}^2 d\tau^2 + d\rho^2 + d\bar{x}_1^2 -\mu^2 (\dot{\rho}^2 \cosh^2 \tau + y_1^2) (d(\rho \cosh \tau))^2 \right) + dy_1^2. 
\end{align}
B Membrane paradigm in the presence of $g_{rt}$

In the metric we obtain, we have an off-diagonal component $g_{rt}$, so in this Appendix we study its effect on the formulas for the membrane paradigm.

B.1 Infalling condition

We would like to find the infalling boundary condition for a metric of the form

$$ds^2 = -g_{tt}(r, t)dt^2 + g_{rr}(r, t)dr^2 + 2g_{rt}(r, t)dr dt + g_{yy}(r)(dx^2 + dy^2).$$

Define first the tortoise coordinate $r^*$ such that

$$ds^2 = dvdu + g_{yy}(r)(dx^2 + dy^2)$$

where $dv = dr^* + dt$, $du = dr^* - dt$. To find $dr^*$ in terms of $dr$ we write

$$dv = dt + dr^* \equiv dt + a dr$$

$$du = dt - dr^* \equiv b dt + d dr$$

which gives a quadratic equation for $a$, namely, $a^2 g_{tt} + 2g_{rt}a - g_{rr} = 0$. Solving for $a$ yields

$$dr^* = a dr = \left( -\frac{g_{rt}}{g_{tt}} \pm \sqrt{\frac{g_{rt}^2}{g_{tt}^2} + \frac{g_{rr}}{g_{tt}}} \right) dr.$$  

Consider now a scalar field $\phi$ near the horizon of a black hole described by the metric (B.1). The infalling condition at the horizon means that $\phi$ can only depend on $r$ and $t$ through the non-singular combination given by the Eddington-Finkelstein coordinate $v$, defined in (B.3). Thus, for fixed $v$, we have $dt = -adr$, and

$$d\phi(v) = \partial_r \phi(r, t)dr + \partial_t \phi(r, t)dt = (\partial_r \phi(r, t) - a\partial_t \phi(r, t)) dr = 0$$

yielding the relation

$$\partial_r \phi(r, t) = a \partial_t \phi(r, t)$$

but now with $a$ as defined in (B.5). Note that in order to recover the usual infalling condition $\partial_r \phi = \sqrt{g_{rr}/g_{tt}} \partial_t \phi$ when $g_{rt} = 0$, we need to take the + solution in (B.5).

B.2 Scalar field calculation

To see the effect of the off-diagonal metric on a membrane paradigm-type calculation, we look at the example of a scalar field.

Consider a massless bulk scalar field with action

$$S = -\frac{1}{2} \int_{r>r_0} d^{d+1}x \sqrt{-g} \frac{1}{g_{d+1}^2(r, t)} \partial_{\mu} \phi \partial^{\mu} \phi$$
where the horizon is at \( r = r_0 \), and we now have allowed for an \( r \) and \( t \) dependent scalar coupling \( g_{d+1}^2(r,t) \). This is to account for the fact that our background fields can now depend on \( t \) as well (see for example equations (4.29) and (4.32)). Following [12], we need to add a boundary term at the horizon to the one that arises from variations of this action. This term is given by

\[
S_{\text{surf}} = \int_{\Sigma} d^{d}x \sqrt{-\gamma} \left( \frac{\Pi(r_0,x)}{\sqrt{-\gamma}} \right) \phi(r_0,x) \quad (B.9)
\]

where \( \gamma_{\mu\nu} \) is the metric induced at the stretched horizon \( \Sigma \), and \( \Pi \) is the momentum conjugate to \( \phi \) with respect to a foliation in the \( r \)-direction, i.e.:

\[
\Pi \equiv \frac{\partial L}{\partial (\partial_r \phi)} = -\frac{\sqrt{-g}}{g_{d+1}^2(r,t)} g^{\mu\nu} \partial_\mu \phi. \quad (B.10)
\]

The “membrane \( \phi \)-charge” is therefore

\[
\Pi_{\text{mb}} \equiv \frac{\Pi(r_0,x)}{\sqrt{-\gamma}} = -\frac{1}{q(r,t)} \left( g_{rr} + \frac{g_{rt}}{g_{tt}} \right)^{1/2} \left( g^{rr} \partial_r \phi + g^{rt} \partial_t \phi \right) \quad (B.11)
\]

where in the last equality we have used the form of the metric (B.1). Now we use the infalling condition (B.7), obtaining

\[
\Pi_{\text{mb}} = -\frac{1}{g_{d+1}^2(r,t)} \sqrt{\Delta} \left( \frac{g^{rr} g_{rt}}{g_{tt}} + \frac{g^{rr}}{g_{tt}} \sqrt{\Delta} + g^{rt} \right) \partial_t \phi \quad \text{(B.12)}
\]

where \( \Delta \equiv g_{rr} g_{tt} + g_{rt}^2 \). If go to the frame of an observer hovering just outside the horizon with proper time \( \tau \), then

\[
\Pi_{\text{mb}} = -\frac{1}{g_{d+1}^2(r,t)} \partial_r \phi. \quad (B.13)
\]

Therefore, the effect of the off-diagonal metric component \( g_{rt} \) gets completely cancelled out and the membrane response \( \Pi_{\text{mb}} \) is the same as in the case of a diagonal metric (see e.g. [6]).

## C Conductivity using \( J^i \) vs. \( F_{ti} \) relation in the presence of \( g_{rt} \)

Consider now a generalization of the action in (2.5), namely

\[
S = \int d^4x \sqrt{-g} \left[ -\frac{1}{8g_4^2} X_{AB}^{\mu\nu\rho\sigma} F_{\mu\nu}^A F_{\rho\sigma}^B \right] \quad (C.1)
\]

with

\[
X_{AB,\mu\nu}^{\rho\sigma} = 2\delta_{[\mu\nu]}^{[\rho\sigma]} T_{AB} - 8\gamma L^2 \delta_{AB} C_{\mu\nu}^{\rho\sigma}. \quad (C.2)
\]
Generalizing the result of section 3, we need to add the surface term
\[ S_{\text{surf}} = \int_{\Sigma} d^3x \sqrt{-\gamma} \left( j^\mu_A \right) A_\mu \]
with
\[ j^\mu_A \equiv \frac{\partial L}{\partial (\partial_\nu A^\mu_A)} = -\frac{1}{2g_4^2} \sqrt{-g} X^{\mu\nu\rho}_{AB} F^B_{\nu\rho}. \]

Thus, the membrane current in this case is
\[ J^i_{mb} \equiv \left( j^\mu_A \right) A_\mu \bigg|_{r=r_0} \]

Using the ansatz (B.1), the only non-zero components of the \( X \) tensor that enter in the right hand side above for \( J^i_{mb} \) are \( X^{riri} \) and \( X^{riti} \), yielding
\[ J^i_{mb} = -\frac{1}{g_4^2} \sqrt{g} \left( X^{riri}_{AB} F^B_{ri} + X^{riti}_{AB} F^B_{ti} \right) \bigg|_{r=r_0} \]

(no sum over \( i \)). Now, for the \( A_i \) component of the gauge fields (we omit the scalar indices \( A, B \) for now), the infalling condition (B.7) at the horizon is
\[ \partial_r A_i = a \partial_t A_i, \quad r \to r_0 \]
which, using the \( A_r = 0 \) gauge and the condition that \( A_t = 0 \) vanishes at the horizon\(^8\), yields
\[ F_{ri} = a F_{ti} \quad \text{as} \quad r \to r_0. \]

This implies that \( J^i_{mb} \) is proportional to \( F_{ti} \) at the horizon as expected, i.e.
\[ J^i_{mb} = -\frac{1}{g_4^2} \sqrt{g} \left( a X^{riri} + X^{riti} \right) F_{ti} \bigg|_{r=r_0}. \]

The factor in parenthesis after some algebra becomes
\[ a X^{riri} + X^{riti} = \Delta^{-1/2} g^{ii} - 8\gamma L^2 \left( \frac{\Delta^{1/2}}{g_{tt}} C^{riri} - \frac{g_{rt}}{g_{tt}} C^{riti} + C^{riti} \right). \]

For our ansatz (B.1), we have
\[ \frac{C^{riti}}{C^{riri}} = \frac{g_{rt}}{g_{tt}} \]
which implies that the last two terms inside the parentheses in (C.10) cancel each other out, giving
\[ a X^{riri} + X^{riti} = \Delta^{-1/2} g^{ii} - 8\gamma L^2 \frac{\Delta^{1/2}}{g_{tt}} C^{riri}. \]

\(^8\)This is required in order to have a nonsingular gauge connection (see, for example, [13])
After some more algebra, we arrive at

$$J_{mb}^i = -\frac{1}{g_{t}^4} \frac{\left( g^{tr} g^{ri} - 8\gamma L^2 C_{riri} \right)}{\sqrt{g} g^{tr}} g_{ti} F_{ri}^i \quad \text{(C.13)}$$

where we also used the fact that $g_{ij} = g_{ii} \delta_{ij}$ to write $F_{ri} = g_{ti} F_{ri}^i$.

In an orthonormal frame of a physical observer just outside the horizon, with proper time $\tau$, we have that $F_{ri}^i = -\sqrt{g_{tt}} F_{ri}^r = -\sqrt{g_{tt}} \hat{E}_i$, where $\hat{E}_i$ is the electric field measured by such observer.

Reinserting the scalar indices $A, B$, and using $T_{AB} = L^2 X_A \delta_{AB}$, we arrive at a conductivity from the membrane paradigm given by

$$\sigma_{mb}^A = \frac{L^2}{g_{t}^4} \left( X_A - \frac{8\gamma g_{ti} C_{riri}}{g^{tr}} \right) \bigg|_{r \to r_0}. \quad \text{(C.14)}$$

Using the formulas at the horizon (5.1) to (5.2), we obtain

$$\sigma_{mb}^{(0)} = \frac{1}{g_{t}^4} \left( 1 + 4\gamma + 28\gamma \mu^2 L^2 \right) \quad \text{(C.15)}$$

$$\sigma_{mb}^{(k)} = \frac{1}{g_{t}^4} \left( 1 + 4\gamma + \mu^2 L^2 + 28\gamma \mu^2 L^2 \right) \quad \text{(C.16)}$$

which are the same we obtained using (3.12).

We can readily check that both of the formulas above give the correct result when the mass deformation is absent, namely [3]

$$\sigma_{mb}^A \to \frac{1}{g_{t}^4} (1 + 4\gamma). \quad \text{(C.17)}$$

Recall that the relation we just obtained here corresponds to the conductivity defined on the horizon membrane. One way to relate to the conductivity at the boundary is to study the $r$ dependence of the current $j_i^i$ and electric field $F_{ti}$, by looking at the equation of motion and Bianchi identities involving $\partial_r j_i^i$ and $\partial_r F_{ti}$ along the lines of Appendix B in [6]. Namely, in our case we have

$$\partial_r j_i^i = GX_{riri} \partial_r F_{ri} + GX_{itti} \partial_t F_{ti} + GX_{ijij} \partial_j F_{ij} + \partial_t (GX_{riri}) F_{ri} + \partial_t (GX_{itti}) F_{ti} \quad \text{(C.18)}$$

$$\partial_r F_{ti} = \partial_t F_{tr} + \partial_t F_{ri} \quad \text{(C.19)}$$

where $G \equiv \sqrt{-g/g_{t}^2}$ and $i \neq j$ (i.e., since the boundary is 2+1 dimensional, $i = y$ and $j = x$ or vice-versa). From here we immediately see that (C.19) implies that $F_{ti}$ becomes $r$-independent in the $k_\mu \to 0$ limit, and that the first three terms in (C.18) will be suppressed in this limit. However, the last two terms in (C.18) will remain finite since they do not involve space-time derivatives of the gauge fields, but only time derivatives of the metric. Since the near horizon metric (4.31), (4.32), obtained by mass-deforming the flat horizon, does have an explicit time dependence – at least for small $t$ - , we cannot rule out, in principle, the possibility that the full metric in the bulk also is time dependent, and we have a nontrivial $j_i^i(r)$, but as we explained in the text, this is not necessarily a problem.
D Conductivity using the Kubo formula at the horizon

In this Appendix we give details about the calculation using the Kubo formula

\[ \sigma(\omega) = -\operatorname{Im} \left( \frac{G_{yy}(\omega, \vec{q})}{\omega} \right) \]  

(D.1)

at the horizon. The boundary term in the action is (we omit the scalar indices for now)

\[ S_{yy} = -\frac{1}{2g_4^2} \int d^3x \sqrt{-g} X^{uyuy} A_y \partial_u A_y \bigg|_{u \to 1} \]  

(sum over \( \mu \)).

(D.2)

Note that in the massless case, i.e. for the pure AdS\(_4\) black hole, the integrand above reduces to \( \sqrt{-g} X^{uyuy} A_y \partial_u A_y \). In our case however, we have an extra term coming from the fact that \( X^{uyty} \) does not vanish in the background (B.1). Therefore, \( S_{yy} \) is

\[ S_{yy} = -\frac{1}{2g_4^2} \int d^3x \sqrt{-g} \left( X^{uyuy} A_y \partial_u A_y + X^{uyty} A_y \partial_t A_y \right) \bigg|_{u \to 1}. \]  

(D.3)

Since we are interested in the conductivity at \( \omega = 0 \), one might naively think that we can simply ignore this second term above on the grounds that the time derivative will produce a term proportional to \( \omega \) in the Green’s function \( G_{yy} \). However, the first term \( \partial_u A_y \), when evaluated on-shell, will also be proportional to \( \omega \), and in fact gives a (leading) finite contribution to the conductivity (D.1). Therefore, we can not simply ignore \( O(\omega) \) extra terms right from the beginning.

Thus, it seems that we need to go back to the Einstein’s equations to obtain the back-reacted Weyl component \( C^{uyty} \) at the horizon. However, we don’t need to, since, in the general background (B.1), we have

\[ X^{uyty} = -\frac{g_{ut}}{g_{tt}} X^{uyuy}. \]  

(D.4)

To simplify even more the integrand in (D.3), we can also take advantage of the infalling condition at the horizon (valid for \( u \to 1 \)) given in (C.7) to write \( \partial_t A_y \) in terms of \( \partial_u A_y \).

Thus, all in all we have

\[ S_{yy} = -\frac{1}{2g_4^2} \int d^3x \sqrt{-g} X^{uyuy} A_y \partial_u A_y \left( 1 + \frac{u^2}{r_0 a(u)} \frac{g_{ut}}{g_{tt}} \right) \bigg|_{u \to 1} \]  

(D.5)

where

\[ a(u) = \frac{u^2}{r_0} \left( \frac{g_{ut}}{g_{tt}} + \sqrt{\frac{g_{ut}^2}{g_{tt}^2} + \frac{g_{uu}}{g_{tt}}} \right). \]  

(D.6)

The second term inside the parentheses in (D.5) was not present in the massless case, when \( g_{ut} \) is zero. However, expanding about \( u = 1 \) gives

\[ 1 + \frac{u^2}{r_0 a(u)} \frac{g_{ut}}{g_{tt}} = 1 + \mu O(1 - u)^{1/2} \]  

(D.7)
which makes it irrelevant for the computation of $S_{yy}$ at the horizon.

The Green’s function we need is therefore

$$G^{(A)}_{yy} = -\frac{3r_0}{L^2 g_4^2} \left( 1 + 4\gamma + h_A(\mu^2) \right) \frac{\partial_u A_y^A(\omega)}{A_y^A(\omega)} \bigg|_{u \to 1}$$  \hspace{1cm} (D.8)

where $h_A$ was defined in (5.7). The last step is to obtain $A_y$ near the horizon. The equation of motion for $A_y$ is

$$A_y'' + \alpha A_y' + \beta A_y = 0$$  \hspace{1cm} (D.9)

where

$$\alpha \equiv \frac{\partial_t (\sqrt{-g} X^{tyu}) + \partial_u (\sqrt{-g} X^{uyu}) - 2i\omega \sqrt{-g} X^{tyu}}{\sqrt{-g} X^{uyu}}$$  \hspace{1cm} (D.10)

$$\beta \equiv -\frac{q^2 \sqrt{-g} X^{xyy} + \omega^2 \sqrt{-g} X^{tty} + i\omega (\partial_t + \partial_u) (\sqrt{-g} X^{tty})}{\sqrt{-g} X^{uyu}}.$$  \hspace{1cm} (D.11)

Inserting the ansatz $A_y = (1 - u)^b F(u)$ into the equation of motion we again obtain $b = \pm \frac{i L^2 \omega}{3r_0}$ near $u = 1$ (independent of $\mu$!). Using the + (infalling) value for $b$ again into the equation for $A_y$ near $u = 1$, we get

$$\frac{F'(1)}{F(1)} \simeq i\omega \left[ \frac{L^2(3 - 28\gamma)}{6r_0(1 + 4\gamma)} + O(\mu^2) \right] + O(\omega^2)$$  \hspace{1cm} (D.12)

for $q^2 = 0$ and small $\omega$. Therefore

$$\left. \frac{\partial_u A_y(\omega)}{A_y(\omega)} \right|_{u \to 1} = i\omega \frac{L^2}{3r_0} \frac{1}{1 - u} + i\omega \left( \frac{L^2(3 - 28\gamma)}{6r_0(1 + 4\gamma)} + O(\mu^2) \right) + O(\omega^2).$$  \hspace{1cm} (D.13)

Putting all this into the Kubo formula (D.1) we obtain once again

$$\sigma^{(A)} = \frac{1}{g_4^2} (1 + 4\gamma + h_A(\mu^2))$$  \hspace{1cm} (D.14)

which matches the other results we obtained.
